4619. Forcing the mulberry. Knight observes, that "the mulberry is a much finer fruit when ripened under glass, in the north of Herefordshire, than in the open air; and in the still colder parts of England it is probably the only means by which it can be ripened at all. The culture of this fruit, by me, under glass, has been confined to plants growing in pots; but I am not acquainted with any species of fruit-tree which, under such circumstances, produces more abundantly, or which requires less care. Its blossoms set equally well in different degrees of heat, and the same continued temperature which will ripen the earlier varieties of the grape in the end of July, will afford perfectly ripe mulberries early in June; and a tree of the latter species, when fully loaded with fruit, presents at least as agreeable an object to the eye as many plants which are cultivated as ornaments only. It is not subject, under common care, to any disease or injury, except the attacks of the red spider; and as the foliage and growing fruit of the mulberry-tree are not at all injured by being watered every evening with clear water, the red spider can never prove a very formidable enemy." (Hort. Trans. ii.)

4620. The barberry is a branchy prickly shrub, rising to the height of eight or ten feet, with ash-colored bark, yellow inside. The flowers appear in pendulous racemes towards the ends of the branches; the corolla, yellow; the berries at first green, but of a fine red when ripe. The flowers appear in May with a cowslip odor; and the fruit, which is of an acid flavor, ripens in September. It is a native of the eastern countries, and also of most parts of Europe, and is found in woods, copses, and hedges in England, especially in a chalky soil. It is generally supposed that the Puccinia, a fungus which closes up the epidermis of the leaves of corn crops, and appears on their surface like rust, is generated by the Acidium berberidis, an insect which inhabits the barberry. (Sir J. Banks on Blight, &c.)

4621. Use. "The fruit is used for preserving, candying, and pickling, as well as for garnishing dishes; the plant is also an ornamental shrub, both when in flower and in fruit."
4622. Varieties. Those most esteemed for their fruit are the following, viz.

Red barberry without stones; which has an agreeable flavor when full ripe. It is sometimes planted when the plant has attained considerable age, and is on a poor soil.

White barberry. (Pol. of Turg. Fr. t.51.) Evergreen; which is the tenderest of them, and should be planted in a warm situation.

Common red with stones. (Duchesn. i. p. 152.) et tab.) This is planted more for ornamental than for use; on account of its beautiful red berries.

Purple-fruited. (Pol. of Turg. Fr. t.50.

4623. Propagation. "All the varieties are propagated commonly by suckers, also by cuttings and layers of the young plants, and occasionally by grafting; the common red sort is also raised by seed; each of which methods of propagation may be performed in the spring; that by suckers and layers may be effected also in autumn."

4624. Soil and final planting. The barberry prefers a light dry soil. One or two plants may be planted in a complete orchard, and trained as standards; but where the shrubbery is the site, it may be allowed to grow as a bush or shrub. "According to the nature of the ground, plant either at any time from autumn, or only in the spring; the plants may be already furnished with a head, pretty well advanced, if thought proper; allow them square distances of from fifteen to thirty feet."

4625. Mode of bearing and pruning. "The barberry produces its fruit at the sides of the branches in small loose bunches; it bears both on young and old wood, chiefly toward the extremities. The branches are, in the young wood,长短 of design be to force out new wood, permit the head to extend freely; and give only occasional pruning, to keep it in a pretty round form, open in the middle; cutting out weak, luxuriant, crossing, superfluous, and decayed branches; reduce also long ramblers, and trim up low strong ones, also lateral shoots on the stem, and eradicate all root-suckers."

4626. As a proportion of the berries ripen in the course of September, they will afford occasional gatherings for present use; and as they will be wholly ripe in October, all that are wanted for domestic supply should be then pulled; always pick them in bunches."

(Abercrombie.)

4627. The common elder is a bushy tree of twelve or sixteen feet in height, much branched, and covered with a smooth grey bark, becoming rough on old stems. The leaves are unequally pinnate. The flowers appear in terminating cymes, and are succeeded by globular blackish-purple berries, mawkishly sweet. It flowers in May, and the berries ripen in July. The whole plant has a narcotic smell, and it is not prudent, we are told, to sleep under it. It is a native of Britain, and many other parts of Europe, and of Africa, Japan, &c. It is common in damp woods and hedges, and is sometimes introduced in cottage gardens and plantations for the fruit, and in forest plantations, exposed to the sea air, as a nurse plant.

4628. Use. The fruit is in demand in many places, but especially in London and the principal English towns, for making elder wine of the expressed juice; a powerful, warming, and enlivening article for the cottager. The tree, professor Martyn observes, is a whole magazine of physic to rustic practitioners, nor is it quite neglected by more regular ones. An excellent healing ointment is made of the green inner bark, which is also purgative in moderate, and diuretic in small doses. A decoction of the flowers promotes expectoration and perspiration, and they give a peculiar flavor to vinegars. The flowers are reported to be fatal to turkeys, and the berries to poultry in general. No quadruped will eat the leaves of this tree; notwithstanding it has its own phalena and aphis. The wood is used by the turner and mathematical instrument maker; and is made into skewers for butchers, tops, angling rods, and needles for weaving nets.

4629. Varieties. Miller mentions several, but those cultivated for their fruit are chiefly the white and black. The scarlet and green barberry may also be used like the black, and are very ornamental trees in the shrubbery.

4630. Site and soil. "As the tree will grow any where, either in open or shady situations, it may be planted in any out-ground or waste spot, in single standards or in rows, to assist in forming boundary fences. Trees planted in the hedge order, if suffered to grow untrimmed, will produce abundance of berries for use."

4631. Propagation and rearing. "The elder is raised by cuttings of the young shoots in the spring, and by seed in the autumn. Select for cuttings some strong young shoots of last summer, cut into lengths of one foot, and thence to three feet or more: these may be planted either where it is intended the plants should remain, or in a nursery for a year's growth. Insert them from six to fifteen inches into the ground, according to their length; they will soon strike root; and will shoot strongly at top the same year. Train those designed for standards with a single stem from three to five feet high; and those for hedges, with branches out from the bottom. To raise this tree from seed: sow in autumn, October, or in early spring in the spring; and they soon in the spring, in the ground, where the plants are to remain; or in a bed or border for planting out when of one or two years' growth."

4632. Final planting. "Standards may be planted from ten to twenty feet apart. They should be allowed to shoot out above to form a branchy head, nearly in their natural order, in which they will soon become plentiful bearers. For hedge-planting, insert cuttings or year-old plants into the sides or tops of banks or ditches, or other suitable boundary lines, a foot asunder. Permit them to branch out from the bottom; and where they are designed for full fruiting, merely cut in the sides a little regular below, leaving them to shoot up. Sow in spring; in hearty growth, for producing large crops of berries."

4633. Taking the crop. "The berries ripen in perfection for the purpose of making wine, about the middle and end of September, and in October, and should then be gathered in bunches."

(Abercrombie.)

4634. The gooseberry in Piedmont, where it is found wild, and the berries eatable, but astrangent and neglected, is called griselle. Some derive our name gooseberry from gooseberry, or the resemblance of the bush to gorse; others, as Professor Martyn, from its being used as a sauce with young or green geese. Garrard says, it is called feaberry (feverberry) in Cheshire, and it has the same name in Lancashire and Yorkshire. In
Norfolk this term is abbreviated to feabes, or, as they pronounce it, fapes. Carberry is another British name for this fruit. The gooseberry-bush is a low, branching, prickly shrub, with trifoliate sub-pubescent leaves, one-flowered nodding pedunclules, and pendulous berries, hairy or smooth. It is a native of several parts of Europe, and abounds in the Vallas in copsewoods, where it produces a small, green, hairy, high-flavored fruit. In England it is naturalised in various places on old walls, ruins, and in the woods and hedges about Darlington. It is cultivated in greater perfection in Lancashire than in any other part of Britain; and next to Lancashire, the climate and treatment of the Llothians seem to suit this fruit. In Spain and Italy the fruit is scarcely known. In France it is neglected and little esteemed. In some parts of Germany and Holland the moderate temperature and humidity of climate seems to suit the fruit; but in no country is its size and beauty to be compared with that produced in Lancashire, or from the Lancashire varieties cultivated with care in the more temperate and humid districts of Britain. Neill observes, that when foreigners witness our Lancashire gooseberries, they are ready to consider them as forming quite a different kind of fruit. Happily this wholesome and useful fruit is to be found in almost every cottage garden in Britain; and it ought to be considered a part of every gardener's duty to encourage the introduction of its most useful varieties in these humble enclosures. In Lancashire, and some parts of the adjoining counties, almost every cottager who has a garden, cultivates the gooseberry, with a view to prizes given at what are called gooseberry-prize meetings; of these there is annually published an account, with the names and weight of the successful sorts, in what is called the Manchester Gooseberry-Book. The prizes vary from 10s. to £5 or £10. The second, third, to the sixth and tenth degrees of merit, receiving often proportionate prizes. There are meetings held in spring to "make up," as the term is, the sorts, the persons, and the conditions of exhibition; and in August to weigh and taste the fruit, and determine the prizes. In the gooseberry-book for 1819 is an account of 136 meetings; the largest berry produced was the top-sawyer seedling, a red fruit, weighing 26 dwts. 17 grs. Forty-six red, thirty-three yellow, forty-seven green, and forty-one white sorts were exhibited, and fourteen new-named seedlings, which had been distinguished at former meetings, stated as "going out," or about to be sold to propagators.

4635. Use. The fruit was formerly in little esteem; but it has received so much improvement, that it is now considered very valuable for tarts, pies, sauces, and creams, before being ripe, and when at maturity it forms a rich dessert fruit for three months; and is preserved in sugar for the same purpose, and in water for the kitchen. Unripe gooseberries can be preserved in bottles of water against winter; the bottles are filled with berries close corked and well sealed; they are then placed in a cool cellar till wanted. By plunging the bottles, after being corked, into boiling water for a few minutes, (heating them gradually to prevent cracking,) the berries are said to keep better. (Neill.)

4636. Varieties. The gooseberry is mentioned by Turner in 1573. Parkinson enumerates eight varieties: the small, great, and long common, three red, one blue, and one green. Ray mentions only the pearl-gooseberry; but Neill has several, and says there are several varieties obtained from seed, most of them named from the persons who raised them; but as there are frequently new ones obtained, it is needless to enumerate them. The present lists of London nurserymen contain from 80 to 100 names; but those of some of the Lancashire growers above 300. Forsyth, in 1800, mentions ten sorts as common; and adds a list of forty-three new sorts grown in Manchester. The following may be considered established varieties, and such as merit cultivation:

4657. Selection of sorts. "It must be admitted," Neill observes, "that although the large gooseberries make a fine appearance on the table, they are often deficient in flavor when compared with some of smaller size. Many of them have thick, strong skins, and are not considered suitable by those who like a thin, firm, and almost transparent rind. Some of the large sort, however, are of very good quality, such as the red champagne and the green walnut. Among these also Wilmot's early red deserves further notice. It was raised by Wilmot, at Isleworth, in 1809, and has been cultivated by him very extensively on account of its valuable properties, being an early ripening, extremely high flavored and easily preserved. It usually ripens from the middle of June to the end of July. For culinary use in the month of May it is larger and better than most others, the skin not being tough, but the whole berry melting to a fine consistence." Forsyth very judiciously recommends cultivating the early and late sorts, in order to preserve this fruit. He states that in the Weald of London, or Manchester red, which is an improved variety of the old ironmonger, is esteemed the best dessert fruit; and the shoots growing upright, the shrub occupies less horizontal space than most other varieties. The walnut red they consider the best sort for preserving. The best mode to obtain a complete assortment of large showy sorts, a numerous variety, or a selection of the most useful sorts: but all the sorts worth having as dessert or kitchen fruit, are in the London and Edinburgh nurseries.

4638. Propagation. The gooseberry may be propagated by all the modes applicable to trees or shrubs; even by pieces of the roots; but the mode by cuttings is usually adopted for continuing varieties, and that by seeds for procuring them.
4633. By seeds. As far as we know, the scientific mode of impressing one variety with another has not been applied to gooseberry. In general, the seed of some characters is set down in autumn or early in spring, in beds or pots of rich light mellow earth: when the plants are a year old they are planted out in nursery rows, to be cultivated and trained there a year or two; in general they will be ready the third year.

4634. By cuttings. Miller says, the best season for planting gooseberry-cuttings is in autumn, just before their leaves begin to fall. The cuttings should be taken from bearing shoots, rather than those gourmands which issue from the main stem. Cut them to such a length as the strength and ripeness of the wood will bear, and cut off all the excepting those at the top of the plants, with a single stem of nine inches, or a foot high, from the top of which the branches should radiate upwards at an angle of 45°, or better if 49°. Haynes advises taking off cuttings in July, when the fruit is on the tree, in order to make some of the fruit ripen. He says, regaining the same object, as from ripe wood-cuttings. (Tr. on the Gooseberry, Sc. p. 92.)

4641. Soil and site. Any good garden-soil, on a dry bottom and well manured, will suit the gooseberry. That which is soft and moist produces the largest fruit. The situation should not be under the drip of trees over much shaded or confined, otherwise the fruit will be small, ill flavored, and the plants apt to mildew. Forsyth says, gooseberries should be dugged every year, or at least have a good coat of dung once in two years. Haynes recommends a mixture of peat and loam well manured, and a shaded situation. The last he proposes to effect by planting among his compartments of gooseberries, rows of Jerusalem artichokes in the direction of east and west.

4642. Final planting. "The season for planting gooseberries is any time during open weather from October till March. When trees are procured from the public nurseries choose such as are of some advanced size, about three years' growth, with pretty full heads, for immediate plentiful bearers. Let the general supply be in standard bushes, and planted principally in the kitchen-garden, in single rows, along the south or north side to the main compartment, or, where they may be there may be planted in cross rows, to subdivide extensive compartments. When the object is to raise large quantities of fruit, plantations are made in continued parallel rows, eight or ten feet asunder, by six feet in the row. It would be eligible to first choice and second choice at the same time, some few choice walls or palings of the larger and lesser fruit; or on north walls, to ripen late in succession. (Abercrombic.)"

4643. Forsyth says, "The market-gardeners about London plant them in rows, from eight to ten feet apart from row to row, and six feet from row to plant in the rows. In small gardens I would recommend placing them in a compartment of 15 ft. by themselves (by six feet), and four feet from plant to plant; or you may plant them round the edges of the compartments, about three feet from the path; you will then have the ground clear for cutting, and a man, by setting one foot on the border, can gather the gooseberries without injuring the plants."

4644. A place of three trees, or some such group of trees, on each side of the borders, are trained to a single tall stem, which is tied to a stake: this, though six or eight feet high, occasions scarcely any shade on the border, and it does not occupy much room, nor exclude air; while, at the same time, the stem becomes close hung with berries, and makes a pleasant appearance in that state. (Ed. Enc. art. Hort. § 161.)

4645. Maher observes (Hort. Trans. ii. 146.), that as "the crop of ripe fruit is often injured, by having the largest and earliest berries prematurely gathered, whilst green, for tarts, a sufficient number of trees of one year's growth, the earliest, are set in a separate compartment of the garden, and devoted exclusively to the use of the kitchen, for tarts and sauce."

4646. Mode of bearing. "The gooseberry produces its fruit not only on the shoots of last summer, and on shoots two or three years old, but also on spurs or snags arising from the elder branches along the sides; but the former afford the largest fruit. The shoots retained for bearers should therefore be left at full length, or nearly so." (Aber.)

4647. Pruning. "The bushes will require a regulating pruning twice in the year."

4648. Summer pruning. "Where any bushes are crowded with cross and water shoots, of the same year, shading the fruit from the sun, and preventing the access of air, thin the heart of the plant and other tufted parts moderately, pinch out the tips, and short-cut the shoots which are tending to bear. Maher says, "it will greatly contribute to the perfection of the fruit, if the very small berries are taken away with a pair of scissors about the middle or end of May; and these small berries will be found quite as good for sauce or gooseberry-cream as the larger."

4649. You may prune at any time, according to the weather, from November until the end of February, or until the buds are so swollen that farther delay would endanger their being rubbed off in the operation. Cut out the cross shoots and water-shoots of the preceding summer, and the superfluous among crowded branches. Prune long ramblers and low stragglers to some well placed lateral or eye; or if an under-straggler spring very low, cut it away. Of last year's shoots retain a sufficient of the best well placed laterals and terminals, in vacant parts, to form successional bearers, and to supply the places of unfruitful and decayed old wood, which, as you proceed, should be removed. Mostly retain a leading shoot at the end of a principal branch, leaving it either naturally terminal, or where the branch would thus be too extended, pruning to some competent lateral within bounds. The superfluous young laterals on the good main branches, instead of being taken off, may be cut into little stubs of one or two eyes; which will send out fruit-buds and spurs. Of the supply reserved for next year, mingle more shorters; Maher's rule will be admirably; cut the shoots in the first instance, where the sprouts are too extended; leave those from eight to twelve inches in length, according to strength and situation; of moderate pretension and regular growth will require very little shortening, and many none at all. Observe, in cutting off the young shoots, the well formed buds, or generally shortening, occasions a great superfluity of wood in summer: when the multiplied laterals thus forced from the eyes of the shorted branches increase to a thicket, so as to retard the growth and full ripening of the fruit: on which account it is an important part of pruning to keep the middle of the head open and clear, and to let the occasional shortening of the shoots become the guide of pruning. Between the leads of the later buds, leaving not more than six at the extremities, which will render them fertile bearers of good fruit. Some persons, not pruning the gooseberry-tree on right principles, are apt to leave the shoots excessively close and tufted, while they should be thinned out as much as possible. Large gardens, in which the frost is not severe, sometimes do not touch in consequence of being pruned in these methods, the bushes shoot croudedly, full of young wood in summer, from which the profit is always very small, and does not ripen freely with full flavor."

4650. Forsyth says, "Many of the Lancashire sorts are apt to grow horizontally, and the branches frequently become loaded with fruit, which is then either injured by high winds, or by weight of fruit they are loaded with fruit. In that case I would recommend two or three 'hoops' to be put round them, to which the branches may be tied, to support them, and prevent their being broken by the wind."

4651. Jenne has tried training gooseberries on an arched trellis, in the manner of a berceau, or arbor-vine. For this purpose, he plants in rows, five feet and a half apart, and the plants three feet distance in the row. He chooses the strongest-growing kinds, and trains four branches, at nine inches' distance.
from each plant, till they meet at top. The advantages of this plan are, beauty of fruit, fruit not
being damaged, easily gathered, and the ground more readily cultivated. (Hort. Trans. vol. iv. p. 194.)

4552. Taking the crop. "From gooseberries being useful for different purposes, both in a green and in
a mature state, and from the compass of time afforded by early and late sorts, they are in season and great
request four or five months in succession. April till September. The last till September, with the
first in small green berries, for tarts, &c. in April or early in May, and attain maturity in June.
From common standard bushes an abundant supply is yielded in May and June of gooseberries in a
green state; and in proportion as part is reserved to ripen, a succession, in full size and
flavour, is obtained in July, during the whole of August, and even till November. Some late kinds, either produced
from the sun in their ripening state, continue good on the tree till September."

4553. Prolonging of the crop. In addition to planting late sorts in shady situations, the bushes,
whence standards or trained, may be matted over when the fruit is ready, and in this way some of the reds,
as the thimble and many other sorts, as the Mogul, will keep on the trees till Christmas.

4554. Sucking. By a preparing very rich soil, and by watering, and the use of liquid manure, shading,
and thinning, the largest fruit of the prize cultivator is produced. Not content with watering at root
and over the top, the Lancashire contributor, when he has his bushes of watered, he only watered under each gooseberry, only three or four of which he leaves on a tree. This is
technically called sucking. He also pinches off a great part of the young wood, so as to throw all the
strength he can into the fruit.

4555. Insectating varieties. Hunt tried planting on half a gooseberry-bush, which half produced ripe
fruit a week sooner than the other, and twice the usual size. (Hort. Trans. iv. 565.)

4656. Insects, diseases, &c. The caterpillars of saw-flies (Tenthredinidae, Leach (fig.
195.), of butterflies (Papilles, L.), and of moths (Phalaena, L.) are well known and serious enemies to
gooseberries. The larvae of the Tenthredinidae have from sixteen to twenty-eight feet; a round head; and when
touched, they roll themselves together. They feed on the leaves of the gooseberry, apple, and most fruit-trees, as
well as roses, and other shrubs and plants. When full-
grown, they make sometimes in the earth, and sometimes
between the leaves of the plant on which they feed, a net-
work case, which, when complete, is strong and gummy, and in that change to a pupa
incompleta, which for the most part remains during the winter in the earth. The
perfect fly emerges early in the ensuing spring; its serrated sting is used by the female
in the manner of a saw, to make incisions in the twigs or stems of plants, where it deposits
its eggs. The Caledonian Horticultural Society having "requested information respecting
the best method of preventing or destroying the caterpillar on gooseberries," received
various communications on the subject, and the following are extracts from such as they
deemed fit for publication: —

4657. Gibbs describes the large black, the green, and the white caterpillars, with their methods of
destroying them. During the winter months, the large black kind may be observed lying in clusters on
the undersides of the leaves; and even in this season (Feb.) I find them in that
state. In the course of eight or ten days, however, if the weather be favorable, they will creep up the
day-time, feed on the buds, and return to their nest during the night. Whenever leaves appear
upon the bushes they feed upon them till they arrive at maturity, which is generally in the month of
June. At this season (July) which they continue to feed on the under sides of the branches, where they lodge till the crust
or shell is formed over them. In July they become moths, and lay their eggs on the under sides of the leaves, and of the bark. The produce of these eggs, coming into life during the month of September,
feed on the leaves so long as they remain, or afterwordseats, and afterwards go into the
leaves, and in crevices of the bark, where they remain all the winter, as already said. Winter
is the most proper time for attacking this sort with success, as their destruction is most effectually
accomplished by the simple operation of pouring a quantity of boiling hot water upon them from a watering
pan, thereby destroying the bushes.

4658. The green sort are at present (Feb.) in the shelly state, lying about an inch under ground. In
April they come out small flies, and immediately lay their eggs on the veins and under sides of the leaves. These eggs produce young caterpillars in May, which feed on the leaves till full grown, and then
become the blackish kind of skin, and afterwards crawl down from the bushes into the earth, where a crust or shell
is formed over them, and in that state they continue till the following April. The only method which I have
hitherto found effectual in destroying these is, 1st, to dig the ground around the bushes very deep during
the winter season, by which means the greater part of them are destroyed, or buried too deep ever
to penetrate to the surface; 2dly, in April, when the flies make their appearance, to pick off all the leaves
on which any eggs are observable; this is a tedious operation, but may be done by children. If any of the
enemy should escape both these operations, they will be discernible as soon as they come to life, by their eating
holes in the leaves, and may then easily be destroyed, without the least injury to the bushes or fruit.

4659. The white kind, otherwise called borers, are not so numerous as the other kinds, though very de-
structive; they bore the berry, and cause it to drop off; they preserve themselves during the winter sea-
on, in the chrysalis state, about an inch under ground, and break the shells near the young spring, when
the leaves are full grown, and in crevices of the bark, and these eggs produce young caterpillars in May,
which feed on the berries till they are full-grown, and then creep down into the earth, where they
remain for the winter in the shelly state. (Caled. Mem. vol. 1.)

4660. Masson,Th. in autumn, show the little cone-serice around the stem of each bush, as much as suffices
must to testen the ground. The bushes which were treated in this manner remained free of cater-
pillars for two years; while those that were neglected, or intentionally passed over, in the same compart-
ment, were totally destroyed by the depredations of the insects. A layer of sand spread laid on in autumn,
and the same year, did the same. (Caled. Mem. vol. 1. 195.)

4661. R. Elliot says, "Take six pounds of black-currant leaves, and as many of elder-leaves, and boil
them in twelve gallons of hot water, then take fourteen pounds of hot lime, and put it in twelve gallons
of water; mix them all together; then wash the infested bushes with the liquor after that is done,
and then lay the bushes on the sand till the leaves of each bush or tree that has been washed, which completes the
whole. By these means any sort of water will do; you can only stir the surface of the earth all round the roots of the
bushes and trees, and lay a little hot lime about them to destroy the eggs. This I have never found to fail
of success since my first trial, six years ago. The above-mentioned proportion of leaves, lime, and water,
will serve for two acres of ground or more, covered with trees and bushes in the ordinary manner, and will cost very little money indeed. The same proportion is to be observed in making a wash for the rest of the trees or bushes."

4653. Mackay procured some tobacco and soft or black soap, and boiled a quarter of a pound of tobacco with one pound of soft soap in about eighteen Scots pints of water, and kept stirring the liquid while boiling with a whisk, in order to dissolve the soap; this liquor, when milk warm, or so cool as not to hurt the foliage, he applied to the bushes with a hand-squirter in the evening, and in the morning found all the ground covered with dead caterpillars covered over with dead dust. This practice he continued for six years, always with success, when he saw any symptoms of the approach of caterpillars.

4654. Tweedie, in the course of one of the winter months, pares all the earth from under the bushes to the depth of about three inches, into a flat ridge between the rows; and on the first dry day, without digging, either trenches, beat, or rolls these ridges, and then deposits the whole down one and a half or two spades deep, observing to tread the soil earth into the bottom of the trench.

4655. Forsyth’s method is as follows: “Take some sifted quick-lime and lay it under the bushes; but do not at first let any of it touch the branches or leaves; the bees, which each bush suddenly and smartly produce, will fall into the lime; if the bush be not shaken suddenly, the caterpillars, on being a little disturbed, will take so firm a hold as not easily to be shaken off. After this is done, sift some of the lime over the bushes; this will drive down those which may have lodged on the branches or leaves; the caterpillars which may next day be observed to be upon the bushes, will be observed to be upon the bushes, will be destroyed any caterpillars that may still remain, and also the aphides, if there are any on the bushes.”

4656. Sweet first syringes the plants, and then powders them with quick-lime by hand, so that every leaf both above and below is covered with it. He found destroyed not only gooseberry caterpillars, but the 6693. Blackcurrant, the thorn or thistle-bush. (Hort. Trans. v. 76.)

4666. Harrison considers, that in the winter season, “the eggs of the insects are deposited in crevices and joints of the tree, also in the ground.” In the pruning season, he burns the prunings, and washes the trees with a mixture of quicklime and water, and then casts in powdered lime among the branches; or, instead of this, he washes the trees with twelve gallons of water, half a pound of tobacco, and six ounces of black pepper boiled together for half an hour, and used when cold. In the following spring, “just before the trees come into bloom,” he sprinkles them with lime-water, and throws on them powdered lime, sprinkled with lime-water at the roots of the trees. Soon after the berries are set, he smokes the trees with straw fires. When summer flies visit the trees, he picks off the leaves on which their eggs are deposited.

4667. "This," he says, “is readily done, and very effectual.” If they increase very rapidly, he uses lime-water as a substitute. (Fr. v. 348.)

4668. Our opinion is, that no reliance is to be placed in powdered hot lime alone, for destroying either the insects or their eggs. Hot water, applied in Gibbs’s manner; lime-water, or water and powder of lime, in the manner of Elliot and Sweet; and digging down, as performed by Tweedie, may be of real service; but the rain seems to be abating the effects of previous hand-picking; which, however tedious it may seem, will often be found a more economical mode than any of the above. Hand-picking, with the spring-generated kinds, should commence as soon as the eggs are observed on the undersides of the leaves, of a white, yellow, or green color, which whole leaf may be picked off, or the eggs brushed or sprinkled off: with the winter kinds it ought to commence as soon as they leave their nidus in the soil or bark and appear on the leaves.

4669. Preventive treatment. Sprinkling the gooseberry and currant bushes with tar-water, prevents the fly or moth from settling on the plant to lay its eggs; this must be done early in the spring, for if done after the fruit is set, it will taste of it. (J. Busch, in Hort. Trans. iv, 583.)

4670. Forcing. The gooseberry may be forced in pots or boxes placed in pits, or in the peach-house or winery. Hay plants in pots in November, removes to the peach-house in January, and has ripe fruit in the end of April, which he sends to table growing on the plants. (Hort. Trans. iv. 415.)

4670. The black currant is an humble shrub, with smooth shoots, strong-smelling tri-lobate leaves and hairy racemes, with a solitary one-flowered peduncle at the base of the raceme. The flowers appear in April, of a greenish-white, and the fruit ripens in June and July, and changes from a green to a black color. It is a native of most parts of Eu- rope, especially the more northern parts. It abounds in the woods in the north of Rus- sia; and in the subalpine regions of Siberia, where the branches and berries are very large and sapid. In Britain, it is found in wet hedges, on the banks of rivers, in alder swamps, and sometimes in woods.

4671. Use. The fruit, which has a peculiar flavor, and disliked by some, is seldom brought to the dessert; but it is eaten in puddings and tarts, and made into jellies, and wines. The Russians put the berries into brandy, and the Irish into whiskey, in the same way as the English put cherries; the Russians also ferment the juice with honey, and so form a strong and palatable wine. Many cottagers, who cannot afford to mix green tea with common bohea, substitute one or two dried leaves of black currant, the flavor produced by which few are so acute as to distinguish from that of a mixture of green and black tea. There are no varieties of the black currant.

4673. Soil and site. A moist soft soil and shady situation, such as is afforded by borders of north exposure is preferable. Miller says, "The fruit is always best when the plants are placed in an open situation, and light loamy soil."

4674. Finest planting. As only a few plants are in general required for private gardens, these may be placed at the distances recommended for gooseberries, in the margin of a shady border, or against a wall of short height of exposure. Neil says, it procures most fruit as a standard, but the largest berries when trained to a wall.

4675. Mode of bearing. The black currant bears chiefly on the shoots of the preceding year, and also from snags or spurs, which, however, are less abundant, and of smaller size in the black currant than in the gooseberry or red currant.

4676. Pruning. Attend to the general directions given for pruning gooseberries, observing to depend less on spurs than on the preceding year’s wood, cutting out the old as it becomes naked and barren, to make room for the new shoots.

4677. Insects and diseases. The black currant is seldom attacked by insects; though, like the elder-tree, it has its own variegated caterpillars, which sometimes reduce it to a state of complete nudity. (6657.)

4678. Gathering the fruit. See Red Currant.

4679. Boying. The black currant may be forced in pots like the gooseberry. In Russia this is often done for the sake of the fragrance of the leaves.

The *red currant* is a low shrub, with smooth branches, doubly serrate, pubescent leaves, yellowish-green flowers on pendulous racemes, which appear in May, and the fruit ripens in June and July. The berries of this shrub, in its wild state, are red; cultivation has produced white and pale-red berried varieties. It is a native of the northern parts of Europe, and found in hedges and woods in England. Professor Martyn observes, that "the currant does not seem to have been known to the ancient Greeks and Romans, as the southern nations of Europe have not even an appropriate name to it at this day." The old French name *groseilles d’outre mer*; and the Dutch, *beskien oversee*, proclaim their having been strangers imported. Our English name of currant is evidently from the similitude of the fruit, to that of the uva coronithiaca, the small grape of Zante, or the common grocers’ corinths, or currants. The red currant has been long cultivated in Britain, and very much improved in the size of the bunch and berried

Use. The fruit is acceptable at the dessert, being of an agreeable acid taste. It is much used for jellies, jams, and wines. Forsyth says, it is the most useful of all the small fruit, either for the table and kitchen, or for preserving, making wine, &c.; and continues longer in succession than any other. According to Withering, the juice forms an agreeable acid to punch; and Professor Martyn says it was a common beverage in Paris in 1763. Its medicinal qualities are similar to those of other subacid fruits, allaying thirst, lessening an increased secretion of the bile, and correcting a putrid and scorbutive state of the fluids.

Propagation and nursery culture. The same as in the gooseberry. With a view to obtaining improved varieties from *Ribes*, that indefatigable horticulturist, Knight, procured cuttings, in the year 1810, of the finest varieties of the red and the white currant, which he planted in pots of very rich mould and placed underneath a south wall, to which the trees were subsequently trained. At the end of three years, within which period the pots had been as often changed, the trees were trained in the form of a very small number, removed from the white currant trees, as soon as their buds unfolded; and those which remained were deprived of their stamens, whilst immature, and subsequently fertilised by the pollen of the red variety. The seeds thus obtained were sown in pots, as soon as the fruit had become perfectly mature, and were subjected, early in the following spring, to the artificial heat of a forcing-house; by which means, and by proper subsequent attention, the plants grew more than a foot in height in the first season. At two years old, in the year 1816, several of the plants, and, in 1817, the greater part of them, produced fruit of great variety of character, and merits; but out of about two hundred varieties, only three red and two white appeared to possess greater merits than their parents. (Hort. Trans. iii. 88.)

Soil and site. All the sorts are very hardy, will grow freely, and bear plentifully almost anywhere, alike in open and shady situations, by the roadside, being obtained which are generally grown for several months in succession till October. As to soil, the currant generally does well in any common garden-ground, well tilled and recruited; it bears the greater crop in a strong loam, or improved clay, somewhat moist; the earlier in a sandy light mould, which is not poor. Previous to planting, the ground should be dug two feet deep.

The season for planting on a dry soil is any time in open weather, from the fall of the leaf till February or March. Plants expected to bear the following summer are best moved in October, unless the ground be wet in winter. Aloft a competent supply of standard bushes, to be placed chiefly in the rows of the main compartments, in the outside and borders, or some in cross rows, to divide extensive compartments. Plant them from five to ten feet distant in the row. To raise large supplies, full plantations are formed in parallel rows, with intervals between the rows of eight or ten feet, and between the trees in each row of six feet. When convenient, have also some sorts trained against walls or paling, of different aspects, to obtain early and late fruit in perfection; some against a south exposure, for early production; others on east, west, and north walls, for intermediate succession and late fruit. Plant them at six, eight, or ten feet distance; letting them occasionally fill up the vacant spaces between other wall-trees. The branches should be allowed to advance from near the bottom, and be trained in a nearly horizontal direction from three to six inches asunder. Before nailing them, cut out superabundant and irregular growths, retaining a competency of regular shoots for ordnary training, among which, if any are of very considerable length, prune them to moderate extent. Some may be allowed to proceed, others trained and detached row, in the borders or divisions of the compartments. The trees so trained may either be left to grow without support, or be tied occasionally to stakes, and the branches thus will not overspread the ground. Being kept moderately thin and regular, they will bear fine large fruit, and make an agreeable appearance."

Mode of bearing. Currant-trees, in general, bear the fruit both on the young wood of one, two, and three years’ growth; and on the older branches, from small spurs, and snags along the sides,—which continue several years fruitful, but the fruit produced on the last year’s shoot is always finest, especially when the old mother bearers have borne more than four years.

Pruning. The chief part of the future culture is seasonable pruning. After the plants are furnished with full heads, they produce many superfluous and disorderly shoots every summer, crowding the general bearers, so as to require retrenchment and regulation, both in the young growths of the year and older shoots. The capital pruning is done in winter, and a preparatory part is performed in summer, to thin the superfluous shoots of the year where too crowded, excluding the sun and air from the fruit. First, as to standards:

Summer pruning. "In May or June cut out close the most irregular shoots rising in the centre of the tree, with all the cross and water-shoots, to admit more freely the essential influence of the air
and sun, and promote the growth of the fruit and improve its flavor. Also twist off all root-suckers as they appear.

468. Winter pruning. "This extends both to the old and young wood; the time for it is when the plant is at rest. Of the shoots of the preceding summer, cut out the cross-placed and the otherwise irregular, with those which are not wanted for vacancies; but superfluous good lateral shoots are to be cut down to short stubs or artificial spurs, about half an inch long, so as to leave an eye or two, in order that there may be new sucker shoots and spurs. With regard to the old bearers, take away those which are stunted, or getting unfruitful, or of which the fruit is declining in size; reduce any of excessive length, pruning in to some well placed lateral young shoot, to preserve the head within some regular compass; cut out also any decayed or cankery parts; retain a constant number of the finest best-placed new shoots above and below the terminal parts, to come in succession; or to supply the places of defective old wood; and preserve a leading shoot to the principal branches, where within orderly limits; shortening such terminal shoots as are of greatest length, to ten, twelve, or fifteen inches, according to their strength and situation on the plant. Close out each year, and leaving that of a mature fruit-shoot in its place, and then take care of the small natural fruit-spurs, and occasionally select short lateral roots of one, two, or three inches, for bearing fruit; or similar small shoots may be cut to short snags of an inch or two long, also for fruiting. Thin out spurs on the old branches where very thick. As the old fruit-branches decline bearing or decay, cut them away, taking care not to lose young ones in succession; and thus keep the trees always furnished with full-bearing branches, and advancing young bearers, in a regular open expansion, six, eight, or ten inches asunder at the extremities; circumscribing the general head within the height of three or four feet, or five at most."

469. Macdonald, at Dalkeith House, Neill observes, "raises currants of the finest quality. A good deal depends on the way in which he manages the bushes, especially during the ripening of the fruit. He prunes the bushes at the usual season of mid-winter, shortening the last year's shoots down to an inch or an inch and a half. Next summer the plants show plenty of fruit, and at the same time throw out strong shoots. As soon as the berries begin to color, he cuts off the summer shoots to within five or six inches before the bush. This is commonly done with the garden-shears, with which a man may go over half an acre of bushes in a day. Sun and air thus get free access, and more of the vigor of the plant is directed to the fruit." Aphis vinifera, the currant aphid, does considerable damage as its white or yellow woolly colonies grow on the young shoots in the spring. Using appropriate pesticides to kill these pests is important to the success of currant production.

4691. To wall-trees, espaliers, and fan standards without support, the same course of summer and winter pruning is applicable, with the obvious variations required by their figure. In training wall-trees, two branches are led in a horizontal direction along the bottom of the wall or trellis, perhaps half an inch from the surface of the earth; and the growth from these of all upright shoots, which will admit of being arranged at the distance of five or six inches from each other, is encouraged. Fan standards are sometimes trained in a manner nearly similar (fig. 496.), and sometimes with the branches raised above the crown of the stock. In the latter case, the young shoots of the crown are cut off, and the young shoots of the side shoots are let out in the usual manner.

4692. Jactets, &c. The red currant is occasionally attacked by the caterpillar (Phalaena graminaria), and very frequently by the Aphis ribis, which changes the color of the leaves to red, pits and puckers them, and prevents the fruit to be shrivelled and flavorless. These are to be destroyed by watering with lime-water, and water alone.

4693. Forsyth says, "As currants are very liable to be devoured by earwigs, which take shelter under their leaves and branches, bundles of bean-stalks should be hung up some time before the bushes are covered with mats or nets. If proper attention be not paid to this, the fruit will generally suffer very much from these insects. After the bushes are covered, take the mats off once in three or four days, and kill the earwigs that have got into the bean-stalk, which it will be necessary still to keep hung up. As there is a mischief in the inside of bean-stalks which attracts the earwigs, they very readily take shelter in them from rain."

4694. Taking the crop and preserving. "The ripening fruit comes in for small gathering in June, advances to maturity in July, and continues in perfection till the end of August; or if trees in a full exposure be left to ripen, and be gathered in September, and still more so in October. Gather in a dry state, as in rainy weather they lose their flavor. (Abcrnethy.)."

4695. Forcing. To obtain early currants by forcing, let some good bearing trees, in pots, be placed, as early as January or February, in any common forcing department: they will produce ripe fruit in April and May.

4696. The raspberry plant has stems which are suffruticosoe, upright, rise about two feet high, and are biennial in duration; but the root is perennial. The leaves are quinate-pinnate, the flowers come in panicles from the extremity of the present year's shoots; they are white, appear in May and June, and the fruit, which in the wild plant is red, ripens about a fortnight afterwards. It is a native of Britain, and not common in woods in low moist situations.

4697. Use. The fruit is grateful to most palates, as nature presents it, but sugar improves the flavor; accordingly, it is much esteemed when made into sweetmeats, and for jams, tarts, and sauces. It is fragrant, subacid, and cooling; alloys heat and thirst, and promotes the natural excretions in common with other summer fruits. It is much used in distilling, to make the verdant spirituous liquor, to which it gives name. Raspberry-syrup is next to the strawberry in dissolving the tartar of the teeth; and as, like that fruit, it does not undergo the aceto fermenting in the stomach, it is recommended to gouty and rheumatic patients.

4698. The varieties are —

| Early small white | Most large red Antwerp | Two-bearing white |
| Large white | Large yellow Antwerp | Two-bearing red |
| Large red | Care or smooth-stalked | Smooth cane, two-bearing |
| | | (Woolward's raspberry) |

(Usk. P. L. t.)
469. Estimate of sorts. "With respect to the varieties of fruit: the first in the above list is a small fruit, but esteemed for its early bearing. The second and third, the common large white and red sorts, are also esteemed in larger crops, as plants bear longer before the two Antwerp sorts are still superior in yielding fine large fruit, and deserve a wall or espalier. The cane-raspberry is a good sort for the main crop. The twice-bearers are esteemed for their singular property of producing two crops of fruit the same year, which the first commonly ripens in July, and the second in September or October; and in fine dry seasons the plants will afford some production from the second crop till November."

4700. Propagation. "The varieties can be perpetuated by young sucker-shoots rising plentifully from the root in spring and summer; when these have completed one season's growth, they are proper to detach with roots for planting, either in the autumn of the same year or the next spring, in February or March, but not later than the middle of April. These new plants will bear some fruit the first year, and furnish a succession of strong bottom shoots for full bearing the second season. New varieties are easily raised from seed; and they come into bearing the second year."

4701. Soil and site. "All the varieties will succeed in any common mould trenched about two feet deep, and sufficiently manured; but the soil in which the raspberry-bush most prosper and bears the finest fruit is a light rich loam. Allow the main crop a free exposure to the sun, that the berries may ripen to perfection. Be careful to favor the twice-bearers with a dry soil, and a sheltered sunny situation; give the second crop every aid in coming to maturity. When raspberries are cultivated on a large scale, it is best to keep them in plantations by themselves. Set these in rows, from four to six feet asunder, as the bushes are of the smaller or larger kinds, by three or four feet in each row. Scattered bushes may either occupy a single row lengthwise along the back part of a border, or stand in detached stools, at ten or fifteen feet distance. Select sorts are frequently trained against walls, stakes, or espaliers, from the most sunny to the most shady aspect, for early and late fruit of improved growth and flavor. "Neil says, 'the raspberries are better in an open place than in the middle of the afraid; for though the place be enclosed by trees, and even slightly shaded, the plant succeeds. In an enclosed and well sheltered compartment, with rather a damp soil, containing a proportion of peat-moss, we have seen very fruitful and well flavored berries produced; for example, at Mevillon House, the seat of the Earl of Leven, in Fifeshire.' Haynes also recommends well manured bog-earth, and a situation naturally or artificially shaded."

4702. New plantation. Raspberry-bushes are in their prime about the third and fourth year; and if well managed, continue in perfection for five years, after which they begin to decline in growth, and the fruit to become small, so that a successive plantation should be provided in time. Select new plants from vigorous stools in full perfection as to bearing."

4703. Summer culture. "Keep them clear from weeds during the summer by hoeing between the rows; at the same time, loosen the earth about the plants. Under this management the plants, if tolerably strong, will both yield a moderate crop the first summer, and supply young stems for bearing in greater plenty and perfection the following season; and so, from year to year, the summer culture should be continued. When the plants get all straggling together, let all the extreme roots of single stools, be cleared out by hoeing, or twisted off, to admit the air and sun freely to the fruit."

4704. Pruning and winter dressing. "It is requisite every winter or spring to cut out the dead stems, and to thin the superfluous young shoots. This is the most important part of the culture during open weather, from November till the beginning of April. When kitchen-garden crops are cultivated between the rows, it is most convenient to do this as soon as the old bearers begin to decay. As to pruning indiscriminately in the open weather of winter, it sometimes happens that severe frosts immediately follow, and partially destroy the plants; therefore it is safer to do the pruning when the young shoots begin to appear early in spring; but let it not be deferred till the buds are making new shoots, as that would weaken the root. Cut out all the old dead stems clean to the bottom; and having selected from the strongest young shoots, three, four, or five, to be preserved, to furnish a succession of bearers, cut away the superabundant close to the ground. Let each of the shoots retained be pruned at top, below the weak shoots part, and cut them in the smaller plants, to about three or four feet in length, and in the large sorts, to the length of five or six feet. If any of the stems diverge irregularly, or struggle much under; then the weak or strong ones will be borne on the strong ones; and if more than one shoot, each of the shoots may have the support of stakes. Prune plants against a wall or trellis as above; and train the shoots to rise a little diagonally. After pruning, having cleared away the cuttings, dig the ground between and about the plants. To turn in a little rich compost every year will conduite to plentiful and fine returns; lay it at the extremities of the roots, and deeper as the plantation gets older. Eradicate all straggling suckers."

4705. To obtain fruit of a very large size. The fruit of the raspberry may be obtained of a very large size, other circumstances being of the most favorable kind, by destroying all the suckers; but in this way, the plant being destroyed, a double plantation is wanted, one to grow only suckers, and the other fruit. In this way Keet, at Berlin, produces plants ten and twelve feet high, with fruit larger than any we have seen in this country. (Vorsch. den Weinbau, & p. 46.)"

4706. Taking the crop. "The fruit of the different varieties comes in from the end of June or July till October or later. As it ripens, it should be timely gathered for immediate use; because, when fully ripe, it will not keep above two or three days before it moulds, or becomes maggoty, and unfit to be used."

4707. Raspberries may be forced equally well with gooseberries and currants, and like them either planted in pots or in the soil of the floor of the house. In M. Hope's garden at Harlem, the raspberry is planted outside along the north and south sides of a pit; the shoots of the preceding year are introduced under the glass and trained to a trellis, and forced while the suckers are left to grow upright in the open air."

4708. The American cranberry (Oxycoccus macrocarpus, P. S.) (Hort. Ker. ii. 7.) is a native of North America, and by the ingenuity of Sir Joseph Banks, it may be said to be now added to our cultivated fruits. The plant was known to Miller, who, of the cranberry tribe, in general, observes, "they can only be cultivated for curiosity in gardens, for they will not thrive much, nor produce fruit out of their native swamps and bogs."

A very interesting account of the mode adopted by the illustrious horticulturist above mentioned is given by himself in the Hort. Trans. i. 71. and of the produce, which was large and uniform. In one year, viz. 1813, from three hundred and twenty-six square feet, or a bed about eighteen square feet, three, and half Winchester bushels of
berries were produced, which, at five bottles to the gallon, gives one hundred and forty bottles, each sufficient for one cranberry-pie, from two and a half square feet.

4700. Culture in moist soil. "Wherever there is a pond," Neill observes, "the margin may, at a trifling expense, be fitted for the culture of this plant, and it will continue productive for many years. All that is necessary is to drive in a few stakes, two or three feet within the margin of the pond, and to place some old boards within these, so as to prevent the soil of the cranberry-bed from falling into the water; then to dig a trench of small width in the bottom, and over the roots or bog-earth the depth of about three inches above, and seven inches below the usual surface of the water. In such a situation the plants grow readily; and if a few be put in, they entirely cover the bed in the course of a year or two, by means of their long runners, which take root at different points. From a very small area a very large quantity of cranberries may be gathered; and they prove a remarkably regular crop, scarcely affected by the state of the weather, and not subject to the attacks of insects." The cranberry will also succeed when planted as an edging to any pond, provided some bog-earth be placed for its roots to run in; or if the bed of bog-earth be sunk in any shady situation, so as its surface may be a few inches below the general level, for the sake of retaining water, the plant will thrive well, and being regularly watered in the driest weather, produce abundant crops.

4701. Cult. ou d'un erbe des fraisiers. "The American cranberry," Salisbury observes (Hort. Trans. ii. 92), "may be cultivated very successfully in situations not positively wet, if only planted in bog-earth, which retains moisture longer than any other soil; for a few plants, even in pots, which had stood some time neglected under a hedge, so that their branches were matted together, produced a plentiful crop." Hallot found the cranberry, and also the bilberry succeed perfectly in a dry bed of peat-earth, so that it may now be cultivated in any garden where that soil can be procured. (Hort. Trans. iv. 483.) Milne also found vigorous shoots and abundant crops produced on dry beds of peat-earth, even in the warm summer of 1822. He finds the American cranberry easier cultivated than the common; but some prefer the flavor of the latter. (Hort. Trans. v. 276.)

4711. The common cranberry (Oxycoccus palustris, L. S.) (Engl. Bot. 519.) may be subjected to the same treatment. "Great quantities of this berry are gathered in upland marsches and turf-bogs, both in England and Scotland. The berries are made into tarts, and have much the same flavor as the Russian imported cranberries, or those procured by cultivation." (Neill.) Twenty or thirty pounds worth are sold each market-day for five or six weeks together in the town of Longtown, on the borders of Cumberland. (Light-foot.)

4712. The strawberry is a small creeping plant, with a perennial root, and, in general, ternate leaves. There are numerous sorts by some botanists distinguished as species, by others considered as only varieties. Knight (Hort. Trans. vol. iii. 207.) considers the grandiflora or pine, the Chibensis or Chili, and the Virginiana or common scarlet, (the first supposed to be a native of Surinam, the second of Chili, and the third of Virginia,) to be varieties only of one species; as all may be made to breed together indiscriminately. The fruit has received its name from the ancient practice of laying straw between the rows, which keeps the ground moist and the fruit clean. They are natives of temperate or cold climates, as of Europe and America. The fruit, though termed a berry, is, in correct botanical language, a fleshy receptacle, studded with seeds.

4713. Use. The fruit is fragrant (whence fragaria), delicious, and universally esteemed. It consists almost entirely of matter soluble in the stomach, and neither there nor when laid in heaps and left to rot, does it undergo the aceto fermentation. Hence it is very nourishing, and may be safely eaten by gouty and rheumatic persons. In addition to its grateful flavor, the subacid juice has a cooling quality, particularly acceptable in summer. Eaten either alone, or with sugar and cream, there are few constitutions with which strawberries, even when taken in large quantities, are found to disagree. Further, they have properties which render them, in most conditions of the animal frame, positively salutary; and physicians concur in placing them in their small catalogue of pleasant remedies. They dissolve the tartaric incrustations of the teeth. They promote perspiration. Persons afflicted with the gout have found relief from using them very largely; so have patients in cases of the stone; and Hoffman states, that he has known consumptive people cured by them. The bark of the root is astringent. (Abercrombie.)

4714. The species and varieties are —

The wood-strawberry (F. rufa) (Engl. Bot. 268.) has the leaves so incised, the fruit round and small, red, white, and green. A native of Britain. The scarlet (F. virginiana) (Dahh. arb. i. t. 5.) with leaves like the preceding; the fruit conical and scarlet-colored. A native of Virginia. Varieties. Early scarlet, one of Wilmott. Late, Wilmott's Coxcomb scarlet. (Hort. Trans. v. 276.)

The rosyberry (F. virginiana) (Hort. Trans. ii. pl. 27.) is an Aberdeen seedling, introduced in 1801; it has a few roundish leaves; larger fruit than the scarlet, and are very prolific. Continued bearing August to.

The Downton (F. virg. var.) (Hort. Trans. ii. pl. 15.) The fruit is large, trigonous, and concave-flat; leaves large; plant hardy and prolific. The Carolina (F. caroliniana); red, from America. Boston. The small or houndberry (F. eddeieur) (Engl. Bot. 2767.) with oval rough bark, flattened; the fruit large, of a pale red color. A native of Britain. The white (F. Chilian) (Dahh. arb. i. t. 5.) with large, oval, thick, hairy leaves and large flowers; the fruit large and scarlet. A native of South America. Keen's imperial, or new Chili (F. Chil. var.) (Hort. Trans. v. pl. 7.) a large showy fruit. Keen's seedling. (Hort. Trans. v. pl. 12.)

The pine (F. grandiflora) (Miller, icon. S. 278.) the leaves small and delicate; there are two sorts, the red and the white, or greenish-tinted, of this most richly flavored fruit. South America. Marthaven castle. Princess Charlotte. The alpine or procumbent (F. collina) which commonly lasts from June till November, and in a mild season, till near Christmas; two sorts of the fruit, the red and the white. Alps of Europe. The chilean (F. chilena) (Dahh. arb. i. 675.) the pulp of the fruit pink-colored. South America.

4715. Modes of propagation. "The plants multiply spontaneously every summer, as well by suckers from the parent stem as by the numerous runners; all of which, rooting and forming a plant at every point, require only removal to a bed where there is room for them to flourish. Each of these separately
planted, bears a fine fruit the following season, and will bear in full perfection the second summer. A plantation of the wild strawberry yields fruit the same year that it is commenced, or the following year, or later from seed, and bring a finer fruit than from offsets. The other species are uniformly propagated by offsets, except the intention be to try for new varieties." Knight, in making experiments, with a view of ascertaining whether most of the sorts would not breed together indiscriminately, raised above four hundred a dozen sorts was sent to the Horticultural Society in August, 1818, and found of various degrees of excellence. The seeds, if sown immediately after being gathered, will produce plants which will bear the following year.

4716. Soil and site. Neil says, "Strawberries are generally placed in a compartment of the garden by themselves, and it should be a place which is freely exposed to sun and air. They are sometimes, however, planted in single rows, as edgings to borders, and in this way they often produce great crops. In either case care must be taken to replenish every fourth or fifth year at the farthest. The alpine and wood species may be placed in situations rather cool and shady; perhaps as an edging in the shrubbery. In such places they produce their fruit perfectly well, and late in the season, which is desirable."

4717. General culture. The following original and excellent instructions for cultivating the strawberry, are given by Keen, of Isleworth; a most successful grower of this fruit. He says, "I will commence with a general detail of my practice: this may be considered as applicable to all the varieties of the strawberry; and afterwards, in noticing each kind that I cultivate, I will specify such peculiarities of treatment as are exclusively applicable to each."

4718. In preparing the soil for strawberries, "if it be new, and, as is frequently the case, very stiff, it should be trenched; but if the bottom spnit of soil, as sometimes happens, be of an inferior quality, I then recommended only a simple digging, placing dung at the bottom, underneath the mould so dung; on the contrary, should the land have been kept in a high state of cultivation, or be good to the full depth, it will be advisable to spnit the top, placing the dung between the spnts. The best way to obtain new plants, is, by planting out runners in a nursery, for the express purpose, in the previous season: for it is a very bad plan to supply a new plantation from old plants. With respect to the time of planting, I have always found the month of March better than any other. Sometimes, when my crop failed, I have had runners planted in the autumn, for the following year, but these have always disappointed my expectations. I plant them in beds, containing three or four rows, and the plants, in each row, at a certain distance from each other, leaving an alley between each bed, the distance of the rows is five feet, the width of the alleys, three and a half feet. The plants are planted. The width of the alleys, as it will afterwards be stated, may appear considerable; but, I am satisfied, that allowing this space for the workmen to stand on, when they water the plants, or gather the fruit, is beneficial, because I have observed in other persons' grounds, where less space is allotted for this purpose, that great damage is done by the workers and the trampling of the people."

4719. General culture. "After the beds are planted, I always keep them as clear of weeds as possible, and on no account allow any crop to be planted between the rows. Upon the growing of the runners, I have them cut when necessary: this is usually three times in each season. In the autumn, I always have the fruit ripened in the bed, for I find it is kept much longer in the garden, from whom it may be convenient, to scatter in the spring, very lightly, some loose straw or long dung, between the rows. It serves to keep the ground moist, enriches the strawberry, and forms a clean bed for the transplanting. It is also a great trouble to have watered alleys, if a more light covering of dung is taken. A short time before the fruit ripens, I always cut off the runners, to strengthen the root; and after the fruit is gathered, I have what fresh runners have been made taken off with a reapng-hook, to gether with the outside leaves around the main plant, after which I take the beds, then hoe them, and rake them again. In the autumn, unless the plants appear very strong, I have some dung dug in between the rows, but if they are very luxuriant the dung is not required; for in some rich soils it would cause the plants to turn nearly all to leaf. I also have to remark, that the dung used for manure should not be too spst; fresh dung from the stable-door is preferable to spit-dung, which many persons are so fond of."

4720. Sorts grown by Keen. The pine Keen grows in a light loam, "though no other kind of strawberry will bear a strong loam better than this. It is likewise to be noticed, that this is of all others the most difficult strawberry from which to procure a good crop. Particular care must be taken that they are planted in open ground: for in small gardens they grow very strong, but seldom bear fruit, in consequence of being so much shaded by standard trees; and I have observed the shade of the walnut-tree to be much more in- jurious to these than to others: for under it they seldom bear at all, but run entirely to leaf. In planting the beds of pines, I keep the rows two feet apart, and put the plants eighteen inches from each other in the row, leaving alleys of three feet wide between each bed: these large distances I find necessary, for the trusses of fruit in my garden-ground are frequently a foot long. The duration of this strawberry, with me, is three years: the first year it bears the best, the second year the crop is very good, and the third year it is less."

4721. The imperial strawberry, "which was raised by myself from seed, may be treated in a similar way, with respect to planting, distance, &c. as the pine; but I have to remark, that it requires rather a light loam, and cannot be planted under trees, nor must it run to leaf, when planted in that situation."

4722. The scarlet strawberry must be treated also like the pine. "With respect to distance for planting the beds of scarlets, I put each row twenty-one inches apart, and each plant eighteen inches distant in the row, and make the alleys two feet six inches wide. The duration of this strawberry, with me, seldom exceeds three years."

4723. The hushtoy "I have always found to thrive best in a light soil: and it must be well supplied with dung, for excess of manure does not drive it into leaf like the pine-strawberry. In planting the beds, each row must be made apart, and the plants must be eight inches distant between the beds three feet wide. There are many different sorts of hushtoys: one has the male and female organs in the same blossom, and bears very freely; but that which I most approve, is the one which contains the male organs in one blossom, and the female in another: this bears fruit of the finest color, and of far superior flavor. In selecting these plants, care must be taken that there are not too many of the male plants among them; for as these bear no fruit, they are apt to make more runners than the females. I consider one male to ten females the proper proportion for an abundant crop. I
learned the necessity of mixing the male plants with the others, by experience, in 1809; I had, before that period, selected female plants only for my beds, and was entirely disappointed in my hopes of a crop. In that year, suspecting my error, I obtained some male blossoms, which I placed in a bottle on the bed of female halfbushes. In a few days, I perceived the flower near the bottle to swell; on this observation, I placed more blossom-plants in other bottles, in which manner they increased, and removing the bottles to fresh places every morning, and by this means obtained a moderate crop where I had gathered no fruit the preceding year. The duration of the halfbush, with me, seldom exceeds three years."

4745. The wood-strawberry is best raised from seed, "which I obtain from fruit just gathered, sowing it immediately in a bed of rich earth. When the plants are of a proper size, I transplant them into other beds, where I let them continue until the March following. They are then placed in rather a moist soil, in beds two feet apart, and in each row kept apart, by the alley between each bed being three feet wide: in this way I produce abundant crops of very fine fruit. I have propagated this strawberry from runners, but never with such good success as from seeds, particularly if the runners were taken from old roots. The duration of this strawberry, with me, seldom exceeds two years."  

4746. The alpine strawberry must always be raised from seed, which should be sown in a bed of rich earth, in the spring. "When the plants are of a proper size, which will be in July or August, I plant them in rows at the back of hedges or walls, in a rich, or in a very moist soil: the rows should be two feet apart, and the distance, from plant to plant, in the rows, twelve inches. My alpines, this year, thus managed, are bearing most abundantly, so much so, that in gathering them there is not room for the women to set their feet, without destroying many. The alpines differ from all other strawberries in quickness of bearing; for no other sort, sown in the spring of the year, will produce fruit, under two years, whereas this yields a crop at the end of one year. Its duration, with me, seldom exceeds two years, and frequently it lasts only one year." (Hort. Trans. ii.) Williams considers that the fruit of plants raised from seed, comes in very well as a late autumn crop, but is certainly inferior in flavor to that produced from transplanted runners. (Hort. Trans. i. 247.)  

4747. The Rev. T. Garnier, a successful cultivator of strawberries, never suffers any of the varieties to remain in the ground more than one year. "Early in August, or as soon as the gatherings are over, I destroy to trench, manure, and prepare the bed for the ensuing year, taking care to select for that purpose the strongest and best-rooted runners from the old rejected plants. If at this season the weather should be particularly dry, I moisten the surface of the ground and much of the roots: I then set out my beds and planting them till the ground is moistened by rain. Such is the simple mode of treatment which I have adopted for three successive years, and I have invariably obtained upon the same spot, a great produce of beautiful fruit, superior to that of every other garden in the neighborhood. Depth of soil I have found absolutely necessary for the growth and production of fine strawberries, and when this is not to be obtained, it is useless, in my opinion, to plant many of the best varieties. It is not generally known, but I have ascertained the fact, that most strawberries generate roots, and strike them into the ground, nearly two feet deep in the course of one season. The pine and roseberry succeed better than any other in stiff and shallow soils, but they should always be planted in an open situation, and not, as is too commonly the practice, in shady and neglected parts of the garden" (Hort. Trans. iv. 480.)  

4748. Young justly blames gardeners for cutting over the leaves of strawberries after they have borne a crop, thereby preventing proper beds for next year, and depriving the plants of their natural protection from the frost. He is also adverse to the practice of digging between the rows in winter, which, he says, cuts off the fibrous roots, and prevents the plants from setting out in spring with that vigor which they otherwise would do. Instead of supplying manure in this way, he recommends the use of liquid manures; or whenever letting a crop remain above three years on the same piece of ground. (Celed. Hort. Soc. Mem. iii. 291.)  

4749. Brick-beds for strawberries. These were observed in a small garden near Chatham, and are thus described: "The beds (fig. 497. a) were upon flat ground, each about three feet wide, and between them were trenches about nine inches wide, and four-inch walls of brick on each side of the trenches (b), to keep up the earth on the sides of the beds. These trenches were about the depth of two or three courses of bricks laid flat, without mortar, and were intended for the purpose of holding water, which was supplied from a pump whenever the ground was dry, while the plants were in fruit. By this method, a much greater crop of fruit was obtained, and the plants continued bearing much longer than in beds where there were no trenches for water. In Devonshire, strawberry-beds are constructed against the side of a hill or bank, by building up beds in steps, with rough granite at the front, to keep up the earth, each step being about two feet high and three feet wide. These steps were filled with good loam, and the surface of each was covered with rough pieces of granite bedded into the loam, leaving openings between the stones, just sufficient to put in the plants. The surface being covered with granite, kept the ground longer in a moist state, and the fruit always clean. If you should expect," observes the writer, "that chippings of stone, such as may be had from the masons in London, might answer the same purpose. I have found a great advantage in keeping the fruit clean, by laying a row of common bricks on each side of the rows of strawberry-plants; I tried plain tiles, but found bricks answer better, as the tiles are apt to be broken in gathering the fruit, and will not do to use a second time." (Atkinson, in Hort. Trans. v. 191.)  

4750. Taking the crop. "The fruit ripens from June to August and September; but the main crop is usually over in July. Gather when the weather is dry, and the same day that the fruit is to be sent to table, otherwise it will soon lose its flavor. Pinch off the calyx and a quarter of an inch of the peduncle, along with the berry."
To have a regular succession of strawberries throughout the autumnal months. This is commonly done by means of the wood and alpine species, and their varieties. Garnier thinks it may be accomplished by late planting; for example, of Wilmot's late scarlet, or the common scarlet about May, the planted runners being in the last days of July, and gathering their crops about the 7th of September. (Hort. Trans. i. 482.) Williams cultivates the alpine for this purpose. "Early in the month of May, when they are in flower, he cuts away all the blossoms, preserving the leaves uninjured; this is again repeated after the middle of June. After this, the blossoms are suppressed, and the plants allowed to continue their flowering, and till cut off by the autumnal frosts. If the first blossoms were not removed, the principal crop of alpines would be ripe at the time the larger strawberries are in season, and consequently of little value; but by this mode of culture, they come into bearing in the latter part of the summer, just at the time the other kinds are over." (Hort. Trans. v. 247.)

For forcing the strawberry, see Chap. VII. Sect. VIII.

Nuts.

Among nuts the most useful in this country is the walnut, both for the dessert and pickling; the filbert is also a very useful fruit; chestnuts are wholesome and nutritious, and, in Spain and Italy, an important article of human food.

The walnut is a large and lofty tree, with spreading boughs, and pinnate leaves, having a very strong aromatic odor. The male flowers come in subterminating aments; the females scattered two or three together in close sessile buds on the young wood near the extremities of the branches. The flower is an ovate, coriaceous, smooth drupe, enclosing an irregularly grooved nut, which contains a four-lobed oily edible kernel, with an irregular knobbed surface, and covered with a yellow skin. The flowers are produced in the end of April and beginning of May, and the fruit ripens in September and October. It is a native of Persia and the south side of Caucasus; but it is supposed to have been introduced here from France, and called "gaul-nut," before 1562.

Use. The kernel, when ripe, is in esteem at the dessert; and the fruit whole, in a green state, before the stone hardens, is much used for pickling. An oil which supplies the place of that of almonds, is expressed from the kernel in France. In Spain they strew the gritings of old and hard nuts, first peeled, into their tarts and other meats. The leaves strewed on the ground and left there annoy worms; or macerated in warm water, afford a liquor which, from its bitterness, may effect their death. The unripe fruit is used in medicine for the same purpose. Pliny says, "the more walnuts one eats, with the more case will he drive worms out of his stomach." The timber is used in this country for gun-stocks, being lighter in proportion to its strength and elasticity than any other. It is almost exclusively used in cabinet-work in most parts of the continent.

The young timber is held to make the finest-colored work, but the old to be finer variegated for ornament.

Varieties. Those commonly cultivated for their fruits are—

Propagation. It has generally been propagated from the nut; and this mode is recommended by Miller, as it produces the trees the most easily from having known that the tree may be continued by inoculation as practiced successfully by Knight. Inarching this tree was long ago recommended by Bouthier, who says, "he found the fruit in this way produced in one third of the time necessary for plants raised from the nut." 1621. Knight, "having planted, in the spring of 1799, some walnut-trees of two years old in garden-pots, raised them up to the bearing branches of an old walnut-tree, and grafted them, by approach, with parts of the bearing branches of the old tree. An union took place during the summer, and in the autumn the grafts were detached from the parent stock. The fruits obtained were planted in a nursery, and, without any peculiar care or management, produced both male and female blossoms in the third succeeding spring, and have since afforded blossoms every season." (Hort. Trans. i. 61.) After numerous trials, he also succeeded in propagating the walnut-tree from budding. "The buds of trees," he says, "are as a rule almost every species, succeed with most certainty when inserted in the shoots of the same year's growth; but the walnut-tree appears to afford an exception; possibly, in some measure, because its buds contain within themselves, in the spring, all the leaves which the tree bears the following summer; whence its annual shoots, it may be supposed, only one or two buds, to all its shoots, of the same season are also, exceptionally, very nearly of the same age: and long before any have acquired the proper degree of maturity for being removed, the annual branches have ceased to grow longer, or to produce new foliage. To obviate the disadvantages arising from the preceding circumstance, I adopted means of retarding the period of the vegetation of the shoots, comparatively with that of the bearing tree; and by these means I became partially successful. There are at the base of the annual shoots of the walnut and other trees, those which join the year-old wood, many minute buds, which are almost concealed in the bark, and which rarely are never vegetating, in the event of the destruction of the large prominent buds which occupy the middle and opposite end of the annual wood. By inserting in each stock one of these minute buds, and one of the large and prominent kind, I had the pleasure to find that the minute buds took freely, whilst the large all failed without a single exception. This experiment was repeated in the same year, upon two yearling stocks which had few in pots, and had been planted during the spring and early part of the summer, in a shady situation under a north wall; whence they were removed late in July to a forcing-house, and instantly budded. These being suffered to remain in the house during the following summer, produced thick shoots, but the small buds, shoots nearly three feet long, terminating in large and perfect female blossoms, which necessarily proved abortive, as no male blossoms were produced at the early period in which the female blossoms appeared: but the early formation of such blossoms sufficiently proves that the habits of a bearing branch of the walnut-tree may be transferred to a young tree by budding, as well as by grafting by approach. The most eligible situation for the insertion of buds of this species of tree (and probably of others of similar habits) is near the summit of the wood of the preceding year, and of course, very near the base of the annual shoot; and if buds of
CHESTNUT.

the small kind above mentioned be skillfully inserted in such parts of branches of rapid growth, they will be found to succeed with nearly as much certainty as those of other fruit-trees, provided such buds be in a manner thrown into the soil in a state more like those of the stocks on which they are inserted."

4738. Carisile (Hort. Trans. ii.) mentions the case of a walnut-tree propagated from the nut in the usual way, on a light soil, on a sandy sub-soil, and in a warm sheltered situation, which produced fruit in six years; but the usual period is eight or ten years.

4739. In the subgenus serocorma Miller, the walnut-tree is propagated, in general, by sowing well ripened nuts of the finest varieties; but as seedlings are apt to vary, new plants are occasionally raised by layers andarching, to continue particular sorts permanent. The nuts may be sown in autumn or spring, in drills, nine to twelve inches deep, plants two inches asunder, and having earthed them in, smooth the surface. They will come up in the spring. When of one year's growth, set out the plants in nursery rows, a foot asunder by six inches in the rows, to remain two years, then be transplanted (doubling the distance) into other nursery lines. Train each with a single stem of six or seven feet high; or in small fields above, to be permitted to branch out and form a specimen head. Layers may be made, in autumn or spring, of young shoots produced near the ground from proper stools formed for that purpose: they will root in one season, to plant out in rows of nursey training as above. Inarching may be performed in February or March upon seedling-walnut-stocks, advanced in proper stems.

4740. Soil and site. The walnut-tree will succeed in any common fertile soil, a light or a clayey loam, so as the sub-soil be dry, and the site a little sheltered; but it thrives best where there is a good depth of loam mixed with sand or gravel rather than clay. As this tree is long before it bears fruit, there is a particular inducement for procuring plants from the nursery, either inarching, budded, or in as advanced a stage as it will be safe to remove them at. This may be when they are from eight to twelve years old, according as they may have been prepared by repeated transplantations. Walnut-trees may be planted in orchards or small paddocks, in a row towards the boundaries; or in parallel double rows in a quincey order, in extensive grounds, but detached from fruit-trees of more contracted growth. The line of walnut-trees, when fully grown, will serve as a screen to the fruit-trees occupying the interior ground. The plants should stand at twenty-five and the trees to fifty feet distance.

4741. Mode of keeping. On the extremities of the preceding year's shoots.

4742. Pruning. Walnut-trees, when finally planted, may be permitted to branch out in their natural order, with the exception of a little occasional pruning, to regulate any casual disorderly growth, to reduce overcrowding of branches, and to prune up the low stragglers.

4743. Ringing to induce bearing, is practised by the Baron de Tschoudi, near Metz, in Lorraine. A zone of bark, two inches broad is taken out, and the part plastered over with cow-dung and loam; the consequence is that the trees prove more prolific, and the fruit ripens sooner.

4744. The way for pruning. Walnuts should be taken for pruning when the internal parts remain tender and fleshy, which may be ascertained by probing them with a pin or needle. The nuts are ripe in September and October, and should then be gathered so as not to injure the tree, and housed in the proper manner for winter use.

Monocr. Poly. L. and Amentees, J. Châtignac, Fr. ; Castanienbaum, Ger. ; and Castagno, Ita.

4745. The chestnut is a large tree, spreading its branches finely on every side where it has room, but, planted closely, will shoot up straight to a great height. The leaves are lanceolate, serrated, and very large. The aments, or catkins, of male flowers are pendulous at the ends of the branches; very long, resembling those of the walnut. They have a strong spemantic smell; the flowers are collected in remote little balls, and are sessile. The proportion of male flowers to the females is prodigious. The calyx of the female flowers becomes an echinate capsule or four valves, of a silky smoothness in the inside, and containing two or three nuts or one only. It flowers in May, and ripens its fruit in October. It is supposed to have been originally brought from Sardis to Italy by Tib. Cæsar. It is so common as to be considered a native in France and Italy; and some consider it as naturalised in England, though it is not likely to propagate itself in this country. Some of the oldest trees in the world are of this species; as that mentioned by Brydone on Etma, and the great tree at Teworth in Gloucestershire.

4746. Use. The fruit is a desirable nut for autumn and winter, and is eaten roasted, with salt, and sometimes raw. Abroad, it is not only boiled and roasted, but puddings, cakes, and bread are made of it. "Chestnuts stewed with cream," according to Phillips (Pomarium Brit. 95.), "make a much admired dish, and many families prefer them to all other stuffings for turkeys." He says, "I have had them stewed and brought to table with salt fish, when they have been much admired." The timber was formerly in very general use in house-carpentry, though some, with every appearance of reason, consider what is generally called old chestnut as old oak.

4747. Varieties. There are none of any note. Some varieties ripen their fruit a few days earlier than others, but none of these have been fixed on and perpetuated by the nurseriesmen so as to be rendered available by purchasers.

4748. Propagation. Miller and most gardeners recommend propagation from nuts; but, for fruit, the Devonshire practice of grafting is decidedly preferable. Sir Joseph Banks says, 4 the nurseriesmen there deal in grafted walnut-trees;" and we may add, that they are now to be had in the London nurseries. (Hort. Trans. i. 62.) Knight says, 4 The Spanish chestnut succeeds readily when grafted in almost any of the usual ways, and when the grafts are taken from bearing branches, the young trees afford blossoms in the succeeding year; and I am much inclined to think, from experiments I have made on this tree, that by selecting the shoots which ripen their fruit early in the autumn, and by propagating with grafts or buds from young and vigorous trees of that kind, which have just attained the age necessary to enable them to bear fruit, it might be cultivated with much advantage in this country, both for its fruit and timber."

Hort. Trans. i. 62.

4749. Soil and site. The tree prefers a sandy loam with a dry bottom; but will grow in any soil on a dry sub-soil. Distribute the plants towards the northern boundary of orchards; and in larger gardens, over any vacant tracts in extensive pleasure-grounds or parks, and to form spacious avenues, or a row along any out-boundary. A great number should not be placed close to a residence, as the smell of the flowers is offensive. Plant them at not less than thirty feet, and thence to fifty feet distance.
4750. *Subsequent culture.*" Permit the trees to branch out freely above, mostly in their natural order, to attain the usual second, third, 
and occasional fourth and fifth branches, 
and low stragglers. After they have attained some tolerably branchy growth, they will come into bearing in moderate plenty; and when they have expanded into large full heads, they may be expected to yield considerable quantities of nuts.

4751. *Taking the crop.* The nuts ripen from the end of September to the end of October. When the outer capsule containing the nuts begins to divide, and the nuts appear of a brown color, and some fall promiscuously from the tree, their full maturity is indicated. They may be gathered by hand, or beat down by long poles. Selecting the finest and best-ripened, clear them from the husks; they will then be well dried and kept in the fruit racks, in thin layers, &c.; and some packed in layers of very dry fine sand for longer keeping." (Abercrombie.)

4752. *The common hazel-nut,* or the filbert in its wild state, is a large-sized shrub, with an ash-colored bark, and alternate roundish cordate leaves. The male catkins appear on the preceding year's shoots in autumn, and wait for the expansion of the female gins in the spring. It is a native of Britain, very common in most woods, and extensively cultivated about Maidstone, in Kent.

4753. *Use.* As a table nut it is in universal esteem; and the wood and twigs of the wild plants are used for sticking pens, forming pegs, number-sticks, staining green-house plants and raspberries, and many other similar purposes in gardening.

4755. *Estimate of sorts.* The common wood-nut, the least desirable for horticultural plantations, may be admitted for variety. The filbert merits culture in a large proportion, and its returns are very profitable for sale. The red-filbert is accounted to have a finer flavor than the white. The cobnut is large, with a thick shell, but the kernel is considerable in size, and sweet. The Barcelona, a good large nut, with a thin shell, is not considered as being imported as well grown here. The long native nut seldom kernels well. The consford is very sweet, kernels well, and the tree is a great bearer.

4756. *Soil and site.* Abercrombie says, "A cool, dry, poorish soil is to be chosen for filbert and nut trees in general; for example, a sandy loam, not clayey stoneware, and with a correct proportion of vegetable or animal remains, for the plants fruit best when but moderately strong. About Maidstone, according to the Rev. W. Williamson, they prefer a hazel loam of some depth, on a dry sub-soil, which they dress every year, as the filbert requires a considerable quantity of manure. They are generally planted on a hard, or in a place which has been previously ploughed, where such is not the case, they are usually propagated by grafting, by layers, or by sowing the nuts. The most advisable methods, because they are certain to keep the respective variety permanent, are, by either grafting them in February or March upon seedling or sucker stocks of the filbert or hazel; or by layering early wood. The nuts are planted in October or November, or in the spring, in a bed of light earth, covering them about two inches. The greater part will germinate in spring, and when the plants are one or two years old plant them out in nursery lines in autumn or spring. Train a principal supply in standards, half-standards, and dwarf standards, each with a single clean stem, from six feet high down to twelve inches." (Abercrombie.) About Maidstone, according to Williamson, they are almost universally propagated by suckers.

4757. *Mode of bearing.* All the species bear principally upon the sides and ends of the upper young branches; and from small shoots, which proceed from the bases of side branches cut off the preceding year.

4758. *Final planting.* "The season for planting all the sorts is autumn or spring, or any interval in mild weather from October till the beginning of March. All sorts should be planted at least one foot distance, to have room to branch out in full heads. In the filbert-grounds about Maidstone it is usual to plant hops, standard apples, and cherries among the filberts. When the filberts come into a bearing state the hops are destroyed, and the fruit trees only suffered to remain. The ground is then planted with gooseberries, currants, &c. and herbaceous vegetables." (Hort. Trans. iv. 152.)

4760. *Pruning.* In the filbert-orchards, about Maidstone in Kent, it is a prevailing practice to train the trees with short stems, like a gooseberry-bush, but with the heads in the shape of a punch-bowl, and exceeding thin of wood, and to prune them with exact attention to the mode of bearing. The filbert is a profligate and extravagant tree, according to Williamson advises to plant them where they are to remain; to suffer them to grow without restraint for three or four years; and then to cut them down within a few inches of the ground. They will push five or six strong shoots which, the second year after cutting down, are to be shortened one foot, to give place to the internodes or equal distances. In the third year, a shoot will spring from each bud; these must be suffered to grow till the following autumn or spring of the fourth year, when they are to be cut off nearly close to the original stem, and the leading shoot of the last year shortened two thirds. In the fifth year, sever half the shoots from the six branches of the ninth year's preceding year, from these the fruit is to be expected, and the future object of the pruner must be directed to produce an annual supply of these by cutting out all that have borne fruit. The leading shoot is every year to be shortened two thirds or more, and the whole height of the branches must not be suffered to exceed six feet. The shoots that is left must be trimmed, which prevents the tree from being feeding in making wood at the end of the branch. Observe, in pruning early in spring, to have a due supply of male blossoms and to eradicate all suckers." Such is the Maidstone practice, which "has been long celebrated," by which 30 cwt. of nuts per acre have been grown on particular grounds, in particular years; but 30 cwt. is considered a large crop, and rather more than half that quantity the usual one, with a total failure three years out of five, so that the average produce is not more than 5 cwt. per acre. Williamson thinks the failure, happening so often, may be owing to the excessive productiveness of the succeeding year, by which "the whole nourishment of the tree is expended in the production of fruit." He recommends leaving the trees rather more in a state of nature, and, from experiments in his own garden, thinks a regular crop in succession will thereby be obtained. (Hort. Trans. iv. 154.)

**Notes.** The leaves are little troubled with vermin of any sort; but the eggs of the weevil (Curculio weevii) (fig. 408, a) and C. puri (b) are deposited in the germen, and nourished on the kernel, which they effectually destroy. The only way of lessening this evil is by taking care to de-
straw all the nuts so infested, in order that the larve may never attain to the fly state.

4762. The Rev. G. Swane having had a plantation of filberts, which for the 30 years of their existence had produced very little fruit, began to suspect a want of male blossoms. He therefore selected a number of oaks from the common hazel, and suspended them over the scarlet blossom of his filberts; and the result was, that the first year he had more fruit than he had during the 20 preceding years. To prove that it was owing to the farina of the male blossoms, he tried some with and some without this assistance, and found the fruit produced as the male blossoms applied. He taught this mode to a neighboring farmer's wife who had a row of barren trees, and she was "much delighted" with the plan; but it in execution the next day, and the same season sent her instructor 6l. of very fine filberts from four old stunted trees that had not borne one for many years. (Hort. Trans. v. 316)

4763. Taking the crop. "The maturity of the fruit is indicated by the cup turning brown, and by the nuts which have also become brown, readily quitting the husk. House a quantity for keeping; gather them in bunches as they grow. If a portion, after being properly dried, be laid in boxes, and covered with dry sand to exclude the air, it will tend to preserve the kernels from shrinking; and they will thus keep well for a month or two." Braddock's mode of keeping nuts two years by closing them up air-tight in emptied butter-firkins has been already mentioned. (2908.)

Sect. V. Native, or neglected Fruits, deserving Cultivation.

4764. Though some of our native fruits recommend themselves by their already known utility, as the cranberry; yet others, as the sorb, haw, &c. are only mentioned with a view of directing scientific horticulturists of leisure and means, to try what can be done in improving them. We shall enumerate them in the order of stone-fruits and berries.

4765. The sloe is the Prunus spinosa, L. (Eng. Bot. 584.) Icos. Monog. L and Rosaceae, J. Ripe, it makes an excellent preserve; unripe, the innsipsited juice forms the German aeciae, and affords an almost indecipherable ink used to mark linens. It is used in home-made wines, to communicate the color and roughness of red port; and the leaves are employed to adulterate the tea of China. Knight and others consider the sloe as the parent of the bullace (P. insititia), and all the varieties of the common plum (P. domestica). As a shrubbery plant the sloe is most ornamental, blossoming before all others of the prunus tribe.

4766. The bird-cherry is the Prunus padus. (Eng. Bot. 1383.) The fruit is nauseous to most palates; but infused in gin or whiskey it greatly improves these spirits, and is only surpassed by an infusion of peach-leaves. A few trees therefore are desirable, especially in Scotland and Ireland.

4767. The mountain-ash is the Sorbus Aucuparia, L. (Eng. Bot. 557.) Icos. Dicent. L. and Rosaceae, J. The berries are eaten in some parts of Scotland and Wales, and afforded an agreeable fermented liquor, and, by distillation, a strong spirit. Grafted on the service-tree, as is frequently done in France, the fruit is said to become larger and more abundant. (Neill, in Hort. Tour. 94.)

4768. The wild service (Prunus tornatilis, W.) (Eng. Bot. 229.) (fig. 493), the bastard service (P. pin-natifida, E. H.) (Eng. Bot. 5231.) (fig. 500), and the whitebark-ash (P. Aria) (Eng. Bot. 1383.), afford agreeable mealy berries, with much less acid than those of the mountain-ash. These trees are most ornamental in shrubbery woods on lawns; and the two last are not undeserving a place in orchards.

4769. The tree-current (Ribes specaturn, L. (Eng. Bot. 1290.) Pentand. Monog. L and Cacti, A.) affords a fruit somewhat smaller and more acid than the common red current; but by crossing and cultivation might, no doubt, be greatly improved; and from its comparatively tree-like habits, might be a more convenient fruit-shrub in respect to crops below or around it.

4770. The common bramble, Rubus fruticosus, L. (Eng. Bot. 715.) Icos. Polyg. L. and Rosaceae, J. The fruit is powerfully acid and astringent, forms agreeable pies and tarts, medicinal gargles, and may also be used raw. There are two single varieties, the white-fruited and smooth, and one with double blossoms.

4771. The cloud-berries, Rubus Chamaemorus, L. (Eng. Bot. 716.) (figs. 50 and 501.) "In Scotland," Neill observes, "the fruit is also called roebuck-berries or knot-berries, and they are perhaps the most grateful and useful kind of fruit gathered by the Scots Highlanders. On the sides and near the bases of the mountains it may be collected for several months in succession. It is not cultivated without difficulty, and it seldom yields its fruit in a garden." By raising from seed, and again from the seeds of plants so raised, and so on for six or eight generations, perhaps at the same time crossing the flowers with those of the bramble or raspberry, in all probability this plant might become a valuable accession to the kitchen-garden. Its berries are ripe in September. (See a curious paper in Caled. Hort. Mem. i. 383.) In Lapland and Sweden the fruit is much prized, and used for a great variety of purposes. Dr. Clarke, as we have seen (581.) found it medicinal. (Scandinavia, chap. xiv.)
4772. The dwarf crimson bramble (Rubus arcticus) (Eng. Bot. 1883.) (fig. 502) produces an excellent berry, found only on the highest and wildest mountains of Scotland. By successive sowing of the seeds on different levels, doubtless it might be brought down, step by step, to live and produce fruit on plains, and in appropriate parts of gardens.

4773. The dewberry (Rubus caesius) (Eng. Bot. 836.) (fig. 503.), the stone-bramble (Rubus saxatilis) (Eng. Bot. 2253.) (fig. 594. a), and the upright bramble (Rubus subreclusus) (Eng. Bot. 2572.) (fig. 504. b), afford agreeable acid and aromatic fruits, which come in late in the season, and merit attempts with a view to accommodating them to habits of cultivation.

The same remarks will apply to a plant common in the woods of Russia and Poland, and which Dr. Clarke has figured, and named Crisia; but which appears to be a species of rubus, and probably a variety of R. subreclusus.

"At Shawhill, near Ha. Difex, it produced fruit abundantly, planted under a north wall, shaded behind by high trees, in a border of sandy peat; and it succeed pretty well in nearly a similar situation at Chapel Allerton, during the eighteen years of my residence at that place, often ripening its berries; but they being little esteemed, I only preserved a patch of it as a rare plant. The flavor of the fruit, however, is exceedingly agreeable to some persons, being strongly perfumed, like eau de noyau, or bitter almonds, and mixed with a pleasant acid. I now regret that I never tried the berries baked with sugar in a tart; if gathered before they are too soft, they may, no doubt, be preserved in bottles, like cranberries, and possibly prove a valuable addition to our winter fruits of that sort." (Salisbury, in Hort. Trans. vol. ii.)

4775. The purple or common bilberry, blackberry, or whortleberry, (Vaccinium Myrtillus, L.) (Eng. Bot. 486.) is another bog-plant common in Britain and the north of Europe. The berries are gathered in autumn for making tarts; in Devonshire they are eaten with clotted cream; in Poland they are ripe in July, and, being mixed with wood-strawberries, and eaten with new milk, are considered a great delicacy. In the Highlands of Scotland they are eaten with milk, and made into jellies. They may be successfully cultivated in a shady border of bog-earth.

4776. The red bilberry, or crowberry, Vaccinium vitis Idea, L. (Eng. Bot. 598.) The fruit is acid and somewhat bitter, but makes a very good rob or jelly, which in Sweden is eaten with all kinds of roast meat, and forms a sauce for venison, which is thought superior to currant jelly. In Wales we have experienced it to be an excellent addition to roast mutton. It may be cultivated in a moist shady border of bog-earth, like the common bilberry.

4777. The broad-leaved whortleberry (Vaccinium amarun, L.) (Bot. Rep. 138.) is cultivated at Enghien, in the Duch d'Aremberg's garden, and the fruit used in the same way as the cranberry. (Nell, in Hort. Tour, 292.)

---

**Horticultural Catalogue. — Exotic Fruits.**

4778. Among exotic fruits we comprehend such fruits as require the aid of artificial heat to bring them to perfection, and among these we have included the vine and the fig; for though these fruits ripen in the open air in very favorable situations and warm seasons, yet it is allowed on all hands, that in by far the greater number of situations and seasons, grapes and figs, grown in the open air, do not attain any thing like their proper size and flavor. Exotic fruits may be arranged as follows:

4779. Those in general cultivation; as the pine, vine, fig, melon, and cucumber.
4780. Those well known, but neglected, as such; as the orange, pomegranate, olive, Indian fig, torch-thistle, and strawberry-pear.

4781. Those little known, some of which seem to merit cultivation; as the akee-tree, alligator-pear, anchovy-pear, durion, guava, granadilla, jamrodsade, malay apple, litchie, loquat, mango, mangosteen, pishamin, and various others.

4782. The varieties of some of these species, as the vine, fig, and melon are very great; in making a selection we would recommended the plan submitted as to the selection of hardy fruits. (4367.)

Sect. 1. Exotic Fruits in general Cultivation.

4783. The exotic fruits in general cultivation include the three first fruits in the world; the pine pre-eminent for its flavor; the vine, for its generous and enlivening juice; and the melon, approaching in flavor to the pine. All circumstances considered, it is doubtful if the durion, mangosteen, and other Indian fruits, equal these; certainly no fruit hitherto discovered in any region surpasses the pine-apple.

4784. The pine-apple is described in Miller's Dictionary (art. Bromelia), as herbaceous; but it is by others considered as a shrub. Its common name of pine-apple is supposed to be derived from the resemblance of the fruit in shape to the cone of some species of pine-tree. In richness of flavor this fruit stands unrivalled; and, as Neill observes, "it is one of the greatest triumphs of the gardener's art, to be able to boast that it can be produced in Britain in as high perfection as in a tropical climate." The leaves of the pine-plant are long, narrow, channelled, and in general furnished with spines or prickles on the edges. The flowers are in a loose spike, on a scape, which is leafy at top; "as the spike ripens, it takes the form of a fleshy scaly strobile, vulgarly called the fruit, and composed of many coadunate berries, which have scarcely any cells or seeds." Professor Martyn doubts whether there may not be some of the fruits with male flowers only, and others with hermaphrodite flowers; "because those fruits which have seeds are remarkably different from the others when cut through the cells, in which the seeds are lodged; for in these they lie near to the centre of the fruit, whereas in those which have abortive cells, they are chiefly close to the rind." South America is generally considered the native place of the pine, though it is indigenous in uncultivated places in Africa, in great abundance. Linnaeus ascribes it to New Spain and Surinam; and Acosta says, that it was first sent from the province of Santa Croce, in Brasil, into the West, and afterwards into the East Indies. Professor Martyn thinks it may be common to the tropical parts of the three continents. The pine-plant has been long cultivated in Jamaica and other West India islands with great success, and was introduced to the gardens of Europe by Le Cour, of Leyden, about the middle of the seventeenth century. This gentleman, Miller informs us, received his first plants from America, and "after a great many trials with little or no success, did at length hit upon a proper degree of heat and management, so as to produce fruit equally good (though not so large) as that which is produced in the West Indies." From Le Cour "our gardens in England were first supplied with this king of fruits;" and it is "commonly said that Sir Matthew Decker, of Richmond, was its earliest cultivator;" but, as a botanical plant, it was introduced so far back as 1690, by Bentick. (Hort. Kew.) Miller informs us, that at first the plants were kept in dry stoves, during winter, placed on scaffolds, after the manner in which orange-trees are placed in a green-house; and that in summer, they were removed to hot-beds of tanners' bark, under frames. They soon, however, began to erect "low stoves," called succession-houses, and bark-pits under deep frames, for the suckers and crowns. Bradley informs us, that by the year 1730, pine-stoves of the different kinds were established in all the principal English gardens; and Justice, in his British Gardener's Directory, published in 1744, states, that pine-apple stoves had also been erected in Scotland, and he gives the plan of one erected by him in his own garden at Crichton, near Edinburgh, in the year 1752, in which the pine was fruited for the first time in Scotland. He recommends such as intend cultivating this fruit, to get their plants and furnaces (the latter cast in one piece) of Scott, of Turnham Green, London, and their thermometers from Coles, in Fleet-street.

4785. Use. It is the first of dessert-fruits; and is also preserved in sugar, and made into marmalades and other confectionaries. In preparing to eat this fruit, first twist out the crown and then cut the fruit into horizontal slices: these being served, the rind and scales of the pips are pared off by the guest with a knife and fork. (Speedly.)

4786. Varieties. There are many varieties of this fruit, independently of some distinct species, as the B. Penguin and B. Karatas; the fruit of these species being sometimes eaten in the West Indies. If the seeds of the ananas were sown frequently in their native country, Professor Martyn considers that varieties might be rendered as nu-
merous as those of the apple and pear. Miller, in sowing the seeds, found a variety of sorts produced from the same fruit; and Speechly mentions, that he raised in 1768 above seventy plants, from seeds sent to the Duke of Portland from the West Indies, most of which varied in some distinctive circumstance, either in their leaves or fruit. Many of these fruits turned out of inferior quality, probably from the seeds having been gathered indiscriminately. Seeds are not usually produced in this country; when they occur it is generally in those pines which blossom in August, and Ripen their fruit in December. (Buch, in Hort. Trans. iv. 535.) The best esteemed varieties in present cultivation are —

The old queen. Fruit oval-shaped, and of a fine color; the fruit, being the hardest kind, and fruited in fifteen or eighteen months. The fruit grows to a large size, often weighing from three to four pounds. It is much more certain of showing in fruit at a proper age and season than most of the other sorts, and has a fruit preference in most hot-houses.

Ripley's new queen. A variety of the old queen, with a large elegant form; fruited also in an equally short period.

Welbeck seedling; fruit small, generally broader at the base than at the top; of a pale yellow, or sulphur color, with very flat pips; flesh white and tender, rich in flavor, with less acidity than is found in most other pines. (Hort. Trans. i. 215.)

Pyramidal, or brown sugar-loaf. Cone-shaped, and dark-colored till it ripens; pips hard and fragrant. Prickly seeded sugar-loaf. Cone-shaped, the fruit of a golden color, the leaves small, spiny, and the pips clear, and small in size. Smooth striped sugar-loaf; similar to the above except that its leaves are larger, its flowers more abundant, and its fruit smaller. Havannah. Tankard-shaped, dark-colored.

Montserrat. The leaves of a dark-brown, inclining to purple in the inside; fruit middle-sized and tun-shaped, and the pips or proportion of the fruit being larger and flatter than in the other kinds.

King pine, or shining green. The leaves of four to five stripes, the pulp hard and rather stringy, but of good flavor when ripe.

Green, or St. Vincent's pine. A rare variety. The fruit is striped like the fruittin of a pyramid; leaves of a brownish tinge, and dropping at the extremities, with strong prickles, thinly scattered. The pips of the fruit are large, often an inch over; and it attains a large size, weighing from three to four pounds. It is of a dark color till it ripens; very juicy, and high flavored.

Black Janacula. The fruit is large, and the plants similar in character and habits to the above.

Providencia pine, or new providence. There are two varieties of this kind, the green, the fruit is larger than that of any of the kinds cultivated in this country; the form inclining to pyramidal; the color at first brownish-grey, but when mature of a pale-yellow. The flesh yellow and melting, abounding with quick juicy juice. Speechly procured in the gardens at Welbeck in 1754, a fruit that weighed five pounds and a quarter, or eighty-four ounces, and from a plant that was not a large one. Griffin had, in 1803, a plant placed under his care, which fruited in July 1804, the fruit of one plant weighing seven pounds seven ounces, and the other nine pounds three ounces, avoirdupois.

This sort, and the two preceding, require generally three years, and sometimes five or six years to produce their fruit. What is called the old providence, is a small fruit from one of the Bermudas of that name.

Blood red; fruit equal in bulk at both ends. Pips of moderate size, color brick red; flesh white and opaque; leaves of a changeable hue; the flavor of the fruit being inferior to that of most of other fruits it is to be considered merely as a curious variety. (Hort. Trans. iv. 214.)

Silver-striped queen. Leaves beautifully striped with white, yellow, and red; but the plant, though elegant, is a reluctant fruitier.

Variegated-leaved pines. Besides the striped-leaved queens, there are several sorts with beautifully variegated leaves and fruits, and some with red or brown leaves; but in general they are tardy in fruiting, and are not considered as ornamental than as useful varieties.

New sorts. Pine plants are frequently imported from the West Indian islands, and in this case generally bear their names. In general, however, these plants are far inferior, both as to kinds and condition, to those grown, and to be procured from nurserymen in this country. They are generally infested with the bug, and very uncertain in their time of fruiting, as well as to their flavor. If these were to be enumerated, the list of pines known in this country would amount to upwards of forty sorts. Specimens of above thirty sorts are grown in the gardens of Gunter, at Earl's-court. The globe pine-apple, a subvariety of the queen, was sent to Washington by the late Mrs. Dewees, and is now reimported under the name of the Russian globe. (Hort. Trans. v. 265.)

4787. The insects which more especially infest the pine are, the brown turtle bug (Coccus hesperidum, L.) (fig. 505. a to e). The female has at first the appearance of a flat scale (a); afterwards, when depositing its eggs, it becomes fixel and turgid (b); these eggs (c) are hatched under the mother, who soon after dies; the young insects, seen under a magnifier, appear like turtles in miniature (d). Only the males (e), which are few in proportion to the females, have wings; these devour nothing, and having performed the office of impregnation, die.

4788. The white scaly bug (C. hesp. var.) (f to l) bears a considerable resemblance to the above; but the scale (f) is somewhat smaller: the color is white, and the males or flies (l) are not so large as those of the brown.

4789. The white mottled crimson-tinged bug (C. hesp. var.) (n and m) differs from the latter in being larger and crimson-colored. Speechly considers it as viviparous. This and the former species are much the most pernicious. The various modes of destroying them, and also the other insects which attack the pine, have been already detailed.

4790. The grape-tineis a trailing, deciduous, hardy shrub, with a twisted irregular stem, and long flexible branches, decumbent, like those of the bramble, or supporting themselves when near other trees, by means of tendrils, like the pea. The leaves are large, lobed, entire, or serrated and downy, or smooth; green in summer, but when mature, those of varieties, in which the predominating color is red, constantly change to, or are tinged with some shade of that color; and those of white, green, or yellow grapes, as constantly change to a yellow, and are never in the least tinged either with purple, red, or scarlet. The breadth of the leaves varies from five to seven or ten inches, and the length of the foot-stalks from four to eight inches. The flowers are produced on the shoots of the same year, which shoots generally proceed from those of the year preceding:
they are in the form of a raceme, of a greenish-white color, and fragrant odor, appearing in the open air in this country in June; and the fruit, which is of the berry kind, attains such maturity as the season and situation admit, by the middle or end of September. The berry or grape is generally globular, but often ovate, oval, oblong, or finger-shaped; the colors green, white, red, yellow, amber, and black, or a variegation of two or more of these colors. The skin is smooth, the pulp and juice of a dulcet, poigniant, elevated, generous flavor. Every berry ought to enclose five small heart or pear shaped stones; though, as some generally fail, they have seldom more than three, and some varieties, as they attain a certain age, as the ascalon or sultana raisin, none. The weight of a berry depends not only on its size but on the thickness of its skin, and texture of the flesh, the lightest being the thin-skinned and juicy sorts, as the sweetwater or muscadine; and what are considered large berries of these varieties, will weigh from five to seven pennyweights, and measure from one to two thirds of an inch in girth. A good-sized bunch of the same sorts may weigh from two to six pounds; but bunches have been grown of the Syrian grape, in Syria, weighing forty pounds, and in England weighing from ten to nineteen pounds. A single vine in a large pot, or grown as a dwarf standard in the manner practised in the vineyards in the north of France, ordinarily produces from three to nine bunches; but by superior management in gardens in England, the number of bunches is prodigiously increased, and one plant, that of the red Hamburgh sort, in the vinery of the royal gardens at Hampton Court, has produced 2200 bunches, averaging one pound each, or in all nearly a ton. That at Valentine’s, in Essex, has produced 2000 bunches of nearly the same average weight.

4791. The age to which the vine will attain in warm climates is so great as not to be known. It is supposed to equal or even to surpass that of the oak. Pliny speaks of a vine which had existed six hundred years; and Bosc says, there are vines in Burgundy upwards of four hundred years of age. In Italy there are vineyards which have been in a flourishing state for upwards of three centuries; and Miller tells us, that a vineyard a hundred years old is reckoned young. The extent of the branches of the vine, in certain situations and circumstances, is commensurate with its produce and age. In the hedges of Italy and woods of America, they are found overtopping the highest elm and poplar trees; and in England, one plant trained against a row of houses in Northallerton (lately dead), covered a space, in 1585, of one hundred and thirty-seven square yards; it was then above one hundred years old. That at Hampton Court, nearly of the same age, occupies above one hundred and sixteen square yards; and that at Valentine’s, in Essex, above one hundred and forty-seven square yards. The size to which the trunk or stem sometimes attains in foreign countries, is so great as to have afforded planks fifteen inches broad, furniture, and statues; and even in this country, the Northallerton vine above mentioned, in 1785, measured four feet in circumference near the ground; and one branch of the Hampton Court vine measures one hundred and fourteen feet in length. Vine timber is of great durability. It may be remarked, that vines regularly pruned and dressed, can rarely attain similar magnitudes, nor is it desirable that they should.

4792. The native country of the vine, like most of our acclimated fruits, is generally considered to be Persia; and Dr. Sickler (Geschichte der Obst. Cult. vol. i.) has given a learned and curious account of its migration to Egypt, Greece, and Sicily. From Sicily it is supposed to have found its way to Italy, Spain, and France; and in the latter country it is believed to have been cultivated in the time of the Antonines, in the second century. It has been found wild in America, and is now considered as a native, or naturalised in the temperate climates of both hemispheres. In the old world, its culture forms a branch of rural economy from the 21st to the 51st degree of north latitude, or from Shiraz in Persia to Coblenz on the Rhine. Some vineyards are to be found even near Dresden and in Moravia; and by means of garden-culture, it is made to produce fruit for the table still farther north; being grown to a considerable degree of perfection in the hot-houses of St. Petersburgh and Stockholm.

4793. The introduction of the vine to Britain is supposed by some to have taken place under the first Roman governors, though, from Tacitus, it appears to have been wanting in Agricola’s time. There is evidence, however, to prove that vineyards were planted here in the year 280, A. D. (see 312.); and Bede, writing in 731, says, there were vineyards growing in several places. Harte observes, that the religious fraternities of the dark ages spread out from Italy in all directions, carrying with them the knowledge of agriculture and gardening; there is little doubt, Professor Martyn remarks, that orchards and vineyards were common appendages to abbeys and monasteries from their first establishment, at least in the southern parts of the island, to the time of the reformation. From this period they have disappeared, in part, perhaps, from the culture of the vine being little understood by those to whom the lands of religious houses were sold or granted; and in part, because a better article would be introduced from our French provinces in the time of the Henries, and continued to be imported when we lost these.
4794. Vineyards have also been planted in modern times, and wine produced, nearly, if not entirely equal, to that of France. In the *Museum Rusticum*, it is stated, that at Arundel Castle in Sussex, the Duke of Norfolk had a vineyard, of which there were in his Grace’s cellar, in 1763, above sixty pipes of excellent Burgundy. Bradley informs us, that Warner, a gentleman of Rotherhith, made good wine from his own vineyards. Switzer mentions several instances, and among others, that of Rocque, of Walham Green, who made wine for thirty years from a vineyard he had planted in a common field-garden. Hanbury and Hales confirm these accounts, and cite others; and Barry, in his *History of Wines*, gives an account of a very productive vineyard, formed by the Hon. Charles Hamilton, at Painshill, in Miller’s time, which succeeded for many years, and produced excellent champagne. It is not yet twenty years since this vineyard was neglected or destroyed. There can be no hesitation, therefore, in agreeing with these authors, and with Miller, Martyn, and Speechly, that vineyards would succeed in various parts of England, and produce wine equal to much of that imported from France. But, in a national point of view, we may conclude with equal safety, that the culture of the vine, as a branch of rural economy, would not be a profitable concern here, on the broad general principle, that it cannot be long worth while to grow any thing at home which we can get cheaper from abroad. The high duties on imported wines may seem to bear against this opinion; but this is merely a temporary cause; for, in the progress of international commerce, governments gradually discover the advantage of leaving trade comparatively free; and in proportion as this becomes the case, each country will feel its advantage in pursuing those branches of industry in which nature or habit has rendered it pre- eminent. It may, however, afford much rational satisfaction for individuals, in favorable situations, to form vineyards, and drink their own wine.

4795. Grapes *for the table* appear to have been in demand as early as the beginning of the 16th century; for Tusser includes “grapes white and red,” in his list of fruits, published about the year 1560; but as far as appears from horticultural literature, the vine had only been grown as dwarf standards, or trained against walls or buildings, till the beginning of the 18th century. Stoves for preserving curious exotics had been introduced soon after the middle of the 17th century; but we find no mention of the application of artificial heat to the vine, till 1718, when Lawrence informs us, in his *Fruit-Gardener*, published that year, “that the Duke of Rutland, at Belvoir Castle, has done so much justice to the vine as to have fires constantly burning behind his slope walls, from Lady-day to Michaelmas; whereby he is rewarded by the largest grapes, and even the best Frontignacs, in July.” These sloped walls, we are informed, were afterwards covered with glass. Switzer (*Pract. Frut. G. 2 edit. 1763.*) appears to be the first author who gives a regular plan of a vineyard, with directions for forcing the grape. He advises making fires as early as the middle of December, so as to make the vines push by the middle of January. Since his time, the art of forcing has made such rapid progress that no kitchen-garden worth notice is now without a vineyard: the fruit is produced in some vineries during every month of the year; and in the London markets is to be had in the highest degree of perfection from March to January. Vines are at the same time still grown on walls unaided by fire-heat, and in favorable seasons, the more hardly early sorts attain a tolerable degree of maturity. In the nursery-gardens of Joseph Kirke at Brompton, a wall upwards of two hundred and twenty yards long, and ten feet high, is covered with plants of the white muscadine, which have produced regular crops for many years. On the border to this wall are standard vines of the same sort, trained to stakes about four feet high, which also bear in proportion, though the fruit does not ripen quite so early, nor attain an equal degree of flavor with that on the wall. In propitious seasons these grapes attain a tolerable degree of flavor; but even then they are of little value, compared to those grown in vineries and hot-houses.

4796. Use. The uses of the grape in Britain are well known; in the dessert it ranks next the pine, and is by some preferred to it. The berries, when green or not likely to ripen, may be used in tarts or pies; and the leaves form an elegant garnish to other table-fruits. Wine is sometimes made in England, by expressing and fermenting the juice, either alone or with that of other fruits; and it has even been made from decoctions of the leaves of some sorts. In warmer climates, the grape is not only used in the dessert, but eaten with bread, either newly gathered or dried as raisins; and in these countries, from the fermented juice, a wine or liquor is made superior to all others for stimulating the stomach, and exhilarating the spirits of man. Some of the most important consequences in the mythological history of man, are referred to its last-mentioned qualities. (See the Histories of Lot, Noah, and Bacchus.) The medical products of the vine are verjuice, formerly used as the juice of lemons: tartar, a gentle cathartic: vinegar, used as a condiment; for extracting the virtues of other medicines; and for counteracting the effects of vegetable poisons. Even wine itself is given as a medicine, in typhus fevers; in nervous disorders; in putrid sore throats; and even in the plague. “In almost all cases of languor, and great prostration of strength,” Martyn observes,
“wine is a more grateful and efficacious cordial than can be furnished from the whole class of aromatics.”

4797. *Varieties.* These are exceedingly numerous; partly from the antiquity of the vine, it having, as Professor Martyrn remarks, been cultivated from the time of Noah; partly from the influence of soils and climates in changing the qualities of grapes, there being hardly two vineyards in France or Italy where the sorts, though originally the same, remain long precisely alike; but chiefly, as far as respects this country at least, from the facility with which new sorts are procured from seed. Tusser, in 1560, mentions only “white and red” grapes. Parkinson, who was more of a horticulturist, gives, in 1627, a list of twenty-three sorts, including the white muscadine, “very great, sweet, and firm; some of the bunches have weighed six pounds, and some of the berries half an ounce.” Ray, in 1688, enumerates twelve sorts as then most in request. Rea, in 1702, gives most of those in Ray’s list, and adds five more sorts, recommending the red, white, and the d’Arbois, or royal muscadine, the Frontignac, and the blood-red, as the fittest sorts for England. The best vines, he says, were then on the walls of the physic-garden at Oxford.

4798. *Switzer,* in 1717, says, “It is to Lord Capel and Sir William Temple that we are owing that collection of good grapes now so plenty in England; the latter,” he says, “brought over the Chasselas, parsley, and Frontignac; and also the Amboyna, Burgundy, black muscat, and grizzly Frontignac; all highly approved, and distributed amongst the nurserymen, as well as the nobility and gentry. The best grapes,” he tells us, “were grown at Islaworth, and Richmond.” Specifically, from 1700 to 1790, excelled in the culture of the vine at Welebeck.

4799. The most valuable modern additions to the varieties of grapes in this country have been procured by sowing the seeds of vines ripened in the hot-houses at Hamburgh, and brought here about a century ago, by Warner, of Rotherhith, already mentioned. Miller in the same way produced the variety of the black cluster, which bears his name. Speeche produced various new sorts, which have now a place in the catalogues of nurserymen. Williams of Pittmanstown, Bradick of Thanes Park, and a particular sort, preserved by the President of the Horticultural Society of England, are variants of the sweet-water, Chasselas, and Hamburgh grapes. The great attention paid to natural history by such as go abroad, has also contributed to the number of grapes. New sorts have been sent from Spain, Italy, and the East Indies, and many from France; so that the lists of some British nurserymen exceed two hundred and fifty names. In France, during the consulate, in 1801, the celebrated chemist, Chaptal, when minister of the interior, ordered a specimen of every known variety of the grape to be collected from the different departments where the vine is grown, and planted in the nursery of the Luxembourg; garden, with a view to ascertain their respective merits. Though this assortment was never completed, the number collected amounted to upwards of three hundred distinct varieties.

4800. A classification of the numerous varieties of the wine has not yet been made, either in France or England. Bosc, the inspector of government-nurseries in France, was employed to compare and class the grapes sent him that they might be described in his history of distinct sorts. The groundwork of his classification was, the color, form, and size of the fruit; the surface, margin, texture, color, and position of the leaves; and the redness, greenness, or variegation of the foot-stalks. From these eleven characteristics combined, he forms 150 classes, in which, he says, may be placed all the possible varieties of grapes. Bosc, aware of the great variety of considerations of another order, which augment the number of characteristics, such as grapes which are in other respects alike, yet differ in their time of ripening, in the time they will hang without alteration on the plant, in the quantity produced on a plant, quality of the pulp, &c., acknowledges, that, after four years’ labor, he could offer no useful result. In the catalogue of the Luxembourg collection, published by Hervey in 1802, the arrangement is, 1. vines with black oval fruits, 27 sorts; 2. black round fruits, 96 sorts; 3. white oval fruits, 64 sorts; 4. white round fruits, 75 sorts; 5. white grapes, 10 sorts; and 6. black round fruits, 10 sorts, 560 sorts.

The most elaborate descriptions of the varieties of the vine which have yet appeared are contained in a Spanish work, *Ensayo sobre las variedades de la vid com., que vegetan en Andalucia,* &c. by D. Simon Roxas Clemente, librarian to the botanic garden at Seville. His character, combined with his vivacity, has procured him a great share of fame, and many excellent and curious sorts. He enumerates thirty-six authors who have written on the vine, since Columbus, by whose names he has distinguished many of his tribes; the others by their local appellations. The table of grape-vines here given is, we acknowledge, very imperfect, but it contains all the information which we have been able to obtain from the best authors, and especially from Speedy and Forsyth. More than triple the names it contains might have been inserted; but, without being accompanied by any descriptive particulars, they could be of no real use.

4801. Estimate of sorts. As it is generally a puzzling consideration for inexperienced persons to make a selection from the ample semi-annual catalogues of authors and long lists of names kept by nurserymen, we shall here submit a few selections suitable to common cases.

Vines to plant against a common garden-wall, or on the walls of a house. The July black, white muscadine, white and black muscat, red muscat, small and large black and white cluster, black muscat, &c.

To plant a vineyard for early fruiting. Take the preceding sorts.

To plant a wall. Will make crop of good grapes of various flavors. Take a white grape, red, or black muscadine, a white and red muscat, white and red Frontignac, a black or red muscadine, a white with red and black muscat, a white and red Frontignac, and Hamburgh, and a white and red Nice.

There are here 35 grapes of 11 distinct flavors; an equal number of both colors; large showy bunches and berries, as well as small black and small grey; small isolated high-flavored ones, as those of the Frontignac; the white placed in the order in which they will ripen. The foliage in summer will be alternately tinged with red and yellow; and, supposing the muscadinies to be placed next the end of which the blue-tinged, they will ripen nearly a month earlier than any of the others: the Muscadin, Frontignacs, and Muscadinies being hot-house grapes; the muscadines will have a sufficient season to ripen them; and the three last sorts, being somewhat more tardy, will come afterwards.

To plant a vineyard for late fruiting. Take the variety of damascens, black and white muscat, black Hamburgh, red and white muscadines, black and white raisins, brown raisins, Peter’s, black prince, &c.

To plant a vineyard in which pine are grown; one plant under each viner. Take the white and red muscat, black and white muscadine, black and red Hamburgh, black and red or white raisins, black Syracuses, red and white raisin, black Damascens: and for early sorts, Sitwell’s sweet-water, royal muscadine, white Frontignac.

To plant a vineyard to run up the reeds of green-house, or potted-places. Choose such sorts as have small leaves and short foot-stalks.

Hardly small-leaved sorts for the reeds of a green-house. Sitwell’s sweet-water, black cluster, black muscadine, parsley-leaved muscadine, black morillon, &c.

Small-leaved sorts, requiring more heat, and if possible, the foot-stalks, of a variety of white muscat, Black Morocco, blue Frontignac, blue tolloc, black galega, and others of the same morillon, &c.

Small-leaved sorts for planting in pots or boxes. Black and white Corinth, black and white cloister, red and grizzly Frontignac, white and red Hamburgh, &c.

</table>
4803. Propagation. The vine is propagated from seed, layers, cuttings, grafting, and inoculation. By seed, for the sake of obtaining new varieties; by layers, to get strong, showy plants the first year; by cuttings, for economy in management, and to get plants with tops proportioned to their roots; and by grafting and inoculation, for various useful and curious purposes.

4804. By seed. The first thing is to select the seeds. If the object be to propagate an esteemed variety from which cuttings cannot be obtained, or to procure a subvariety of any esteemed sort, the best method is to select the largest and frailest of the fruit, out of which to take the seeds. But if the object be to procure an entirely new variety, then the first preparatory steps must be taken when the vines are in flower, either by bringing two or more sorts so near together as that the pollen of the anthers may effect a promiscuous impregnation, as was practised by the ancient Greeks; or by causing two sorts to be impregnated, before their anthers had burst, and introducing the pollen of the variety with which it is to be crossed or impregnated, by dusting the stigma with the ripe anthers, as was practised by Knight. This is the most certain and effectual method; the best method, because it is only when the fruit is erived to a state of maturity that the pollen is expansive or fit to propagate the new variety; the most effectual, because the stronger pollen alone must have more influence on the progeny when than when operating in conjunction with that of the blossom to be crossed.

4805. An account of the selection of sorts to breed from, to borrow the phraseology of a sister art, we may state, that the legitimate object which ought to be had in view, should not merely be to obtain a

4806. new variety, but one, either superior in the size, both of the bunch and berry, superior in flavor and delicacy of skin and flesh, superior in point of hardiness, in readiness or lateness. In consequence of these particular, the form of the bunch, and the length of the foot-stalk of the fruit, and even the size of the leaves of their foot-stalks, are objects deserving attention; close-growing berries, which always have short foot-stalks, being subject to many misfortunes.

4807. All the sorts of berry growing, viz. 

4808. those produced in the black, blue, and red Frontignacs; and they do not partake so much of the strong muscat flavor as the white and grizzly do. But it must be considered, that the blue Frontignac grows close upon the bunch, and therefore it is only proper to be coupled with the smaller bunches, and the berries being very large and well flavored, it must be a proper kind to be coupled with many sorts. There is a peculiar delicacy in the flesh of the white sweetwater; it is also a remarkably thin-skinned grape, with large berries; consequently, it is a variety most suited for consumption, together with the

4809. and hardy kinds. Of these in particular, the form of the bunch, and the length of the foot-stalk of the fruit, and even the size of the leaves of the foot-stalks, are objects deserving attention; close-growing berries, which always have short foot-stalks, being subject to many misfortunes. But...
a successful instance of this practice from layers made in a vinery; but when taken from stools in the open air, it happens almost always that the roots of the layer are not ripened; the consequence of which is, that their extremities rot off, and the following year the plants make hardly any shoots. Layering without, or but with a trifling incision, as is too frequently done in the hurry of nursery business, greatly contributes to this effect, by obliging the shoot to derive all its nourishment from the parent plant or stool, to which, in autumn, the descending sap is returned. Whereas, when a deep incision is made, or a ring of bark taken off in Williams’s manner (2168.), less sap ascends, the shoot is not so long, it ripens sooner, and the descending sap reposes in, and ripens the roots. It is not easy to conceive in what way plants so raised can be inferior to those raised from cuttings of one or of several eyes; though it appears to be the general opinion that they are not so long-lived as plants raised from one eye. "Vine-plants raised by layers," Speechly observes, "are much inferior to plants raised by cuttings, both in point of future vigor and durability." Hitt wonders how any one can prefer cuttings to layers, since the former are always one year beyond the latter.

4809. By cuttings. The advantages of propagating by cuttings are economy in labor, economy in the wood or shoots to be propagated from, and tops or shoots proportioned to the roots. There are three kinds of cuttings used in propagating vines:—

4810. Long cuttings. The first are from a foot to eighteen inches long, consisting of new or young wood, with a joint or two of that of the preceding year. This is the sort recommended by Miller; adopted in forming vineyards on the continent; and formerly also in this country in planting walls or vining regular woods. This eye is inserted so as to the upper joint only is above the ground; the lower part, to which the old wood is attached; they are mulched, and water is supplied regularly in dry weather. Cuttings of this sort, so treated, strike freely, as Speechly observes, either with or without heat. We have seen them in some French nurseries producing luxuriant shoots and branches of grapes the first year. Justice says he prefers stock-planting a vineyard from such cuttings to using rooted plants.

4811. Short cuttings. The second mode is that of forming the cuttings with only one eye on young or one-year-old wood, and of the preceding year. A few inches of the top growth, a two-inch piece of the two-inch old wood, with one eye of the new. The bottom part should be cut perfectly smooth; plant in pots, one cutting in each pot, which, as to size, should be a forty-eight. When the plants begin to grow, and the pots full of roots, it will be necessary to shift them from the forty-eights to the thirty-two's."

4812. Single eyes. By the third mode, the cuttings have only a single eye on young or one-year-old wood. This mode was first adopted by the Rev. M. Mitchell, and is by him recommended to Speechly, although "it is rather an enigma." The following is Speechly's reasons for its preference: "It is well known that young cuttings are generally preferable to layers, and that plants of any sort raised from small cuttings, commonly make the best plants. The new plant is injured in proportion as it partakes too abundantly of its original or mother plant. Hence, the less the bulk of the matter that forms the new plant the better; for plants raised from seed have the smallest beginning of any, and are preferable both to layers and cuttings." (Tr. on Vine, 52.) Perhaps, the chief advantage of propagating by eyes in preference to short or long cuttings or layers, is, that the sets are more manageable, and can be more readily potted and placed in pots or frames to receive bottom heat; on which, applied early in spring and continued through summer, accompanied by proper shiftings and waterings, much more than on the form of the cuttings, depend abundance of roots and fitness for bearing the second year. We have seen single eyes raised in pineries, produce strong shoots from ten to twenty feet the first year, and others, in cold frames or pits, with only a little bottom heat to start them, in spring, produce earlier shoots, not longer than two or three feet. Ripe wood is to be chosen for propagating by eyes; and though some of are of opinion that cuttings taken from the lower part of the vine are preferable to those that grow higher and at a distance from the root, yet Speechly says, he never could find any difference, provided the shoots, from vines for early, were cut, he does think the most preferable; and these will generally be found at the most distant parts from the root, as vines generally break first at the extremities of the shoots: and at these extremities will be found both the strongest, earliest, and best-ripened wood, and the most abundant buds. Very short eye (Truck Vining, 70)."

4813. By grafting. The advantages of this mode of propagation may not at first sight appear, but they are, Speechly observes, "many and important." First, when a wall, or vineyard, is planted with inferior kinds of vines, the usual method of stubbing them up and supplying their places with better sorts, is attended with much expense and loss of time: as several years must elapse before the wall can be completely finished with new vines; but, by grafting, the nature of the vines may be changed without expense or loss of time; for I constantly have good grapes from the same year's graft; and in a hot-house the grafts, if permitted, will frequently shoot thirty or forty feet the first summer. Secondly, in small vineyards, or vine-frames, where it would be inconvenient to have any considerable variety of sorts from roots, they may be procured by grafting different kinds upon one and the same plant. A Syrian vine now (1759) growing in the hot-house at Welbeck, produces sixteen different sorts of grapes. But the most important advantage, Speechly considers to be, "the improving the various kinds"
of grapes, and particularly the small kinds, which generally make weak wood. By grafting the weak and delicate growing vines, as the blue Frontignac, upon robust and vigorous stocks, as the Syrian, it will produce well-sized handsome bunches, almost as large as those of the Hamburg. The Syrian vine, raised from seed, is greatly preferable to all others for stocks. If the seed degenerate to a kind of wildness, so much the greater will be the vigor of the plants, and the higher the flavor of the sorts grafted on them. At the pruning season select cuttings for grafts from the best bearing branches, in general preferring the bottom part of last year’s shoot; preserve them, by inserting them three parts of their length in pots, till wanted. The season for grafting in stoves is the beginning of January; in the open air, the middle of March. On small stocks, two years potted, are to be preferred for the open air; but, for a vineyard or hot-house, plants from the nursery may be potted, or shifted, if already in pots, and inarched the same season. In whip or cleft grafting, the clay may be taken off when the scion has made shoots five or six inches long; but here both clay and bandage should remain two or three months after the graft has formed a union, lest the grafted part spring from the stock.

4814. Knight finds grafting most successful when the lower part of the scion consists of two-year-old wood, and when the graft is well covered with clay kept moist, or if the branch be on a horizontal trellis with a pot or saucer placed under the graft, and the point of junction kept well covered with earth occasionally renewed. (Hort. Trans. iv. 482)

4815. Braddock has made several experiments on grafting vines: he found the scion generally sdden by the bleeding of the stalk; but, at last, he contrived by a very close bandage round the graft to force the sap of the stock up through the vessels of the scion, when the latter grew. From these, and various other experiments, he found that he could make the most vigorous growth of scions from young wood of the preceding year’s growth, from the time that the shoots of the stocks which the grafts are to be put upon, have made four or five eyes, until midsummer, with every prospect of the graft’s growing, and without the least danger of the stock suffering. They may likely be grafted with shoots of the same season’s growth, worked into the rind of the young wood, from the time that the young bunches of grapes become visible on the stocks till July, out of doors; or till a month later, under glass. The operation must not be performed later than the periods here specified, because time is necessary for the young shoots of the graft to become hard and ripen before winter.” (Hort. Trans. v. 482)

4816. Culture. For the culture of the vine in the forcing department, see Chap. VII. Sect. II. What follows concerns chiefly the management of vines in the open air.

4817. Soil. The vine will thrive in any soil that has a dry bottom; in such as are rich and deep, it will grow luxuriantly and produce abundance of large fruit; in shallow, dry, chalky, gravelly, or schistous soils, it will produce less fruit, but of better flavor. The greater part of the vineyards of France, Bose observes (Cours complet d’Agriculture, écc art. Vigne), are on a soil argil-calcaire: sometimes primitive, as those near Dijon; and sometimes secondary, as those at Bourdeaux. Argilaceous gravel is the next in frequency, as near Nismes and Montpellier, and that which produces the Vins des Graves of Bourdeaux. Both good and bad wines are produced from the débris de granites; among the former are the côtes roties and hermitage on the Rhone. The excellent wines of Anjou and Touraine, made from vines growing in the white marl of the Loire, are the best. Grapes, planted in chalky soils, are weak, colorless, and do not keep well, as those of Champagne. Wines grown on the ashes discharged from volcanoes are excellent, as those of Vesuvius and Etne. Soils surcharged with oxide of iron, red or yellow, are not less proper for making good wine. Retentive and highly charged soils for the worst inadmissible. If it sets, does not ripen; the shoots not ripening well are more easily affected by frosts; and the vine, if any can be made, is weak and flavorless. Such a soil, even when in a warm climate, is particularly obnoxious to the vine, as Bose observed in the botanic garden established at Charleston, in South Carolina, and in France at Bordeaux. The vine grows there on a kind of artificial hill, of clayey soil, well drained, and with the bottom covered with good loam or sand. This circumstance, he considers, will prevent the successful culture of the vine in that part of America.

4818. Switzer observes, that the soil for the vine should be light, having a bottom of clay; travel under a surface of about two feet deep and free from springs; it cannot be too hot nor too dry, provided it be not in its own nature so very barren that nothing will grow upon it. If given to brambles, it is a certain sign of fitness, as plant whatever is so co-natural to the vine as this shrub. In chalky-bottomed lands, and in gravel, which is not springy or speckled, the vines are the best; and likewise, of a sandy and where there is much sand, we dare not plant vineyards, and even Paris itself excel us. (Fr. Fruit Gard. 149).

4819. Hitt, having observed a vine at Belvoir Castle growing out of the stony foundation of a wall, without any other roots than those which were fixed therein, producing better fruit, and earlier ripening, than any other in these gardens, mixture of the latter, with the latter, brick-hatts, &c. for a foot deep in the bottom of wall-borders destined for the vine. (Tr. on Fr. 12).

4820. Lawrence says, “he cannot easily be brought to think that any soil or situation can be too dry for the roots of the vine, after having seen at Barnwall, near Oundle, a flourishing vine grow from between those walls of grey sand, where they are so deep and dry that they almost reach the level of the wall, which is itself a foot high from the ground, and which produced admirable crops of grapes when well managed.” (Fruit Gard. 149).

4821. Specificity says, “the soil in which I have known the vine to prosper in the most superlative degree without artificial assistance, is in the neighborhood of sandy loam, in beds like jointed slate or stone, so very soft in its nature as almost to be capable of being crumbled between the fingers.” Strong and deep lands most proper for tillage are the least so for vines, and hence the introduction of vineyards would have no bad effect respecting agriculture.” (Tr. on the Vine. 247).

4822. Speechly says, “soil should not be deprived of its roots by pruning, nor its size or shape be reduced to a kind of black mould. Soot, wood-ashes, pigeons’ and hens’ dung, he considers too hot for the root of the vine; pond-mud and moor-earth too cold. Stableyard dung is too spirituous, hot, and fiery, when introduced directly into the heat of summer: some advantageous, if introduced into vine-compost. Vines are greatly injured in their roots by the common practice of laying lime-rubbish for the bottom floor in the preparation of the ground. Blood, the offal of animals or shambles’ manure, horse-shavings, old rags, hair, shavings of leather, bone-dust, dung of deer and sheep, and human ordure,” are admissible when duly mellowed by time, a win-
ter's frost, and repeatedly turning over. The dust and dirt of roads, Speechly greatly esteems as a manure for vines; its fertile nature he attributes, "in part, to the dung, urine, and other rich materials of which it is composed; and in part to a kind of magnetic power impressed upon it by friction, and its perpetual piling on to old walls." It is generally considered for the immediate use of vine-growers take every sort they can get: the more careful, however, form composts of earths, leaves, weeds, cleanings of ditches, rivers, and ponds, which they turn over a year at least before using. In some places, littery dung is buried in trenches between the rows; but in general, the dung, of whatever kind, is spread over the green crops, and regularly turned under them. Green crops (Guise, Complect, &c. art. Vigne.) Forsyth considers the best manure for vines to be a mixture of vegetable mould, rotten spit-dung, and fresh loam; these ingredients should be thrown into a heap, and frequently turned a year or two before it is used. This is best suited to by all gardeners, the fertility of both the soil and the root stock. Bacon and Valentine's vines are attributed to their roots having found the walls of houses, and a former into a large common sewer, and the latter into a pond of stagnated muddy water. (Hort. Trans. ii. 357.) Some vines in the hot-houses at Earl's Court produced abundance of blossoms the second year from planting young wood, which is now covered with moss and with the renewed name of some vines the third year are producing two crops, one of which is now ripe and the other in blossom. The cause of this extraordinary fertility appears to be the soil of the border, which is composed of equal parts of garden-earth and blood mixed together, and repeatedly turned over one or even two years before using.

4823. *Vine-walls.* A south wall is always to be preferred for vines; though, in some years, the harderier sorts may attain a tolerable degree of perfection on a wall considerably inclined to the east or west. Vines, Speechly observes, do well on low walls six feet high; and it has been found that the plants grow stronger, and afford larger grapes when they do not exceed four or five feet in height; they enjoy in this way both the reflected heat of the wall and of the earth. Flued walls have been tried for vines in some parts of the north of England; but Speechly, and English gardeners in general, do not approve of the practice. In Scotland, though flued walls are more common and better understood, yet vines are seldom planted in the open air. For standards or plantations in the way of vineyards, Switzer recommends, "that side or declivity of a hill lying to the south or south-east, which, if favored with other hills, somewhat higher, clothed with wood on the north, north-east, and north-west, will break the severity of those pelashing quarters." Speechly concurs in this opinion, adding, that the hills in the counties bordering on the English channel, have in general declivities tending to the south, and are, therefore, highly favorable for vineyards. Steeps of poor gravelly and rocky soils, in warm situations, would produce more under vines than under any other crop.

4824. *Sorts for the open air.* Some of these have been already enumerated. (4801.) And an addition may be made from the lists described in the table.

4825. *Planting.* Where a wall is to be entirely covered with vines, three plants of a sort may be planted at the distance of three, or if a large-leaved kind, of four feet from each other; the two outer plants to be considered as temporary, to fill the wall and produce a supply of wood; and the centre plant, in consequence, may be kept for the supply of wood to fill the space remaining by the death of the others. The temporary plants will, therefore, be trained chiefly on the upper part of the wall, and the permanent ones below; and in four or five years the latter will be in a state to cover the wall, when the former may be rooted out. When vines are only planted in the intervals between other fruit-trees, or on piers, to be trained within a narrow upright space, then one plant to each is sufficient. Some however, as Forsyth, place two against a pier, one on each side; but this is more to obtain a variety of sorts than to fill the space.

4826. In pruning and training in the open air, any of the modes described as applicable to forced vines (2965.) may be adopted. As they break more regularly in the open air than when forced, the spur-method (fig. 455.) and the fruit-tree method (fig. 456.) seem to deserve the preference.

4827. *Williams,* of Pitmaston, (Hort. Trans. iii. 550.) describes a mode of training so as to fill up the vacancies of other fruit-trees, which seems well deserving attention. "A vine," he says, "might be trained horizontally under the coping of a wall to a great distance, and by inverting the bearing shoots, that they could reach the top of the other fruit-trees. If the top of the wall was reached by the vines were inarched to the horizontal branch, the south wall of a large garden might be furnished with a variety of sorts from the stem and root of a single plant, the roots of which would not encumber the border in which the other fruit-trees were growing. This is an experiment of this kind now in progress in my garden. Within a few years past, I have gradually trained bearing branches of a small black cluster-grape to the top of nearly fifty feet from the root, and I find the bunches every year grow larger, and ripen earlier as the shoots continue to advance. According to Knight's theory of the circulation of the sap, the ascending sap must necessarily become enriched by the nutritious particles it meets with in its progress through the vessels of the albumen; the wood at the top of tall trees, therefore, becomes short-jointed and full of blossom-buds, and the fruit there situated attains its greatest perfection. Hence with vines which come on piers loaded with fruit, this most convenient situation on the terminal branches of the oak, and the finest mast on the houghs of the beech and chestnut; so like apples, pears, cherries, &c. are always best flavored from the top of the tree. But I suppose there are certain limits beyond which the sap would be so loaded with nutriment that it could not freely circulate.

4828. *Training the shoots of vines along the ground* like those of melons and cucumbers has been proposed by Vispre (Disc. on the Growth of Wine in Eng. Bath, 1786.), and was practised by him on a small scale at Chelsea, where "the grapes were considerably larger than those of the same kind growing on a south wall." Bacon has represented to me this mode of training these vines are suffered to grow like herbs, spreading upon the ground, and the grapes of these vines are very large, &c." It appears from Vispre, that the Rev. Mr. Le Broc had taken out a patent for training from the earth in this manner. Speechly, "Fruit-trees are trained from a root eleven feet long for fourteen years!" and we have seen the practice adopted in the Earl of Selkirk's garden at St. Mary's Isle in Kircudbrightshire, above fifteen years ago.

4829. *Growing the vine on espaliers.* This may be done, following the same directions in all respects as for forced vines but it is evident that, under such treatment, the fruit will not come to the same degree of maturity as when enjoying the shelter and reflection of a compact screen. Where wine is made from green grapes, as is now frequently done, the practice may be preferable to growing the vine as dwarf standards.

4830. *Growing the vine as standards.* This practice may be adopted either in the borders of gardens, or in extensive plantations as vineyards, and the plants may be trained either like red currants or raspberries. In the former case no stakes are used; but about a foot from the ground, three or more shoots, 3 C 3
eighteen inches or two feet in length, diverge from the stem, and supply young wood annually for bearing. The summer pruning consists in removing shoots which have no fruit, or are not wanting for the succeeding season; in topping fruit-bearing shoots, and also those for the succeeding years, when inconveniently long, and for training. For this mode the shoots destined to bear are all cut into three or four eyes at the winter season, no inconvenience arises from their throwing out laterals near the extremities, which stopping will generally cause them to do. This mode is adopted in vineyards on dry rocky situations where they do not stick much to wood. In training standard vines, as raspberries, the single stem at bottom is not allowed to extend more than eight inches in height, and from this two or three shoots are trained or tied to a single stake of three or four feet in length. These shoots bear each two or three bunches within a foot or eighteen inches of the ground, and they are annually succeeded by others which spring out that is, from the top or base of the dwarf main stem. This is the mode practised in the north of France and in Germany; in the south of France and in Italy, the base or main stem is often higher, and furnished with side shoots, in order to afford a greater supply of bearing wood, which is tied to one or more poles of greater height. The summer pruning in this case is nearly the same as in the last. In the winter pruning, the wood that has borne is cut out, and the new wood shortened in cold situations to three or four eyes, and in warmer places to six or eight eyes.

4831. Formation of vineyards. A vineyard is a collection of standard vines, planted in rows of a greater or less width, according to the height and mode of training proposed to be adopted; and according as the soil may be rich and deep, or poor and thin, or its surface flat or inclined. A square yard of surface to each plant, when they are kept low, may be considered as a desirable medium.

4832. Where plantations of vines are made on the sides of very steep hills, it is sometimes customary to form the surface into terraces or horizontal beds rising one above another. The width of these beds or terraces depends on the declivity or declivity of the hill, but in general, the irregularity of the declivity and surfaces of hills, causes a very great inequality in the breadth and height of the terraces, and in these cases the vines are planted according to the degree of declivity afforded by the terraces. The walls which support these platforms in vine-countries, are generally too rude to admit of training against them, and therefore one of the standard modes above described is almost always adopted.

4833. Proper form for the continuous vine. Stacked best for making wine are by no means the most agreeable to eat; and there is always a clear distinction made between fruits to eat, and fruits for the press, by the nurserymen, who, in general, have only plants of the former sort for sale. The names of vineyard-grapes vary in every district; so that were it desirable to procure sorts from France or Germany, only a general order could be given. In this country, however, it would probably, in the event of planting a vineyard, be found preferable to select from the sorts already acclimated, and rendered hardy by many years' culture and propagating from seed, such as the clusters, sweetwaters, espionce, &c. The sorts planted in the vineyard at Painshill, were the Burgundy, or large black cluster, and the miller-grape, or small black cluster. The vineyard-grapes in France, Germany, and Italy, and we are informed, in Spain, Portugal, and every other wine-country, may be considered as varieties or subvarieties of the black cluster; and the vines which are grown to produce sweet wines, as the Constancia and Malmsey Madeira, varieties of the chasselas or muscadine.

4834. Making of wine from grapes. The making of wine is a part of domestic economy that can hardly be considered as included under gardening. We shall, therefore, merely suggest, that where grapes are to be pressed in any quantity, the management of the liquor should not, if possible, be left to mere empiric practitioners. Some knowledge of the general principles of fermentation will help to guard against accidents, and direct in doubtful cases. The assistance, therefore, of a person possessing some knowledge of chemistry, or one who has been concerned in the manufacture of British wines, will be found desirable on such occasions. An excellent paper "On the Processes of Wine-making," will be found in the second volume of the "Transactions of the Horticultural Society of England," by Matthew, in the "Hort. Trans. ii.," has given a receipt for making a very tolerable sort of red wine from the leaves of the clarat grape; these leaves, it is suggested, might be employed to give color to wine produced from certain sorts of white grapes, green gooseberries, or other fruits producing a colorless fermented liquor.

4835. Insects which infest the vine. The red spider, of which there are many sorts, attacks the leaves in spring, or early in summer; increases prodigiously in dry weather, and soon damages and destroys the foliage. Speechly says, red spiders "generally reside and breed on the under side of the leaves, and the infested leaves are very distinguishable as soon as they are attacked by them, for the insect wounds the fine capillary vessels with its proboscis, and this causes the upper surface of the leaf to appear full of very small dots, or spots of a light color. When the acari are very numerous, they work a fine web over the whole under side of the leaf, as also round the edges thereof; and it is curious enough to observe, that they commonly carry this web in a straight line, from one angular point of the leaf to another, on which boundary line, in a warm day, they pass and re-pass in very great numbers. Watering is the only effectual means of destroying this insect."

(The on the Vine, 162.) The thrips (Thrips, L. Lar. and Leach.) is more injurious to vines in the forcing department than to those in the open air. However, if young shoots chance to receive any injury from late spring frosts, the tender part of the leaf will immediately curl up, and change to a dark-brown color; and in this state, the thrips generally attacks them with great greediness, especially the white sweetwater and white muscadine kinds. The green fly sometimes attacks vines; but seldom so as materially to injure them. Smoking destroys
both insects. There are two or three kinds of coci, or turtle insect, that sometimes infest the vine, \( (Coccus hesperidum \) and \( adonidum, \) but they rarely do much injury in the open air.

4835. The blue fly \( (Musca vomitoria, \) Latr.) attacks the fruit when nearly ripe, before the wasp or birds begin to devour it. Forsyth says, "As soon as it makes its appearance, you must provide betimes plenty of bottles, a little more than half filled with some sweet liquor, to entice them to enter and be drowned. Hang the bottles on the nails, at proper distances, all over the vines, and also near the bottom of them." 4837. The wasp \( (Vespa vulgaris, \) and in some places the hornet \( (V. Crabro, fig. 506, \) attacks the fruit like the blue fly, and is to be destroyed in a similar manner; or by tying up the bunches in gauze bags. 4835. Birds of various species, but chiefly the smaller kinds which may abound in the neighborhood, also attack grapes. A few of them may be shot and hung up as scares; or bagging may be adopted; or where there is a full regular crop over the wall, trellis, or standards, the trees may be protected by netting or bunching. The latter will protect them also from the fly and wasp.

\( (Hort. \) 4835. The fig-tree is a low tree, a native of Asia and Barbary; naturalised in Italy and the south of France, and enduring the open air in the mildest parts of Britain. The fig-tree in France and Italy grows as large as our apple-trees, but in this country seldom exceeds two yards in height; the trunk is about the thickness of the human arm; the wood, porous and spongy; the bark, ash-colored; the branches smooth with oblong white dots; the leaves annual in Europe, but perennial within the tropics, cordate, ovate, three or five lobed, thick, and the size of the hand. The fruit is a berry, turbinate and hollow within; produced chiefly on the upper part of the shoots of the former year, in the axils of the leaves on small round peduncles. The flower is produced within the fruit; what is considered as the fruit being a common calyx or receptacle: the male-flowers are few, and inserted near the opening in the extremity of the receptacle, or fruit; the female flowers are very numerous, and fill the rest of the hollow space within. The greater part prove abortive, both with and without the process of caprification. The fig forms an important article of culture in the isles and borders of the Mediterranean sea, and especially in Greece, Italy, and Spain. It is also much cultivated for drying in the south of France; and for the table, at Argenteuil, near Paris. The earliest notice we have of its culture in England is by Turner in 1562. The first trees were brought over from Italy by Cardinal Pole, in 1525, during the reign of Henry the Eighth, and yet exist in the gardens of the archbishop at Lambeth. They are of the white Marseilles kind, and still bear delicious fruit. They cover a space of fifty feet in height, and forty in breadth; the circumference of the trunk of two of the trees is twenty-eight, and of another twenty-one inches. In the severe winter of 1813-14, these trees were greatly injured, and in consequence their principal stems were cut over near to the ground; but they are fast recovering. At Oxford, in the garden of the Regius Professor of Hebrew, is a fig-tree, which was brought from Aleppo, and planted by Dr. Pocock, in 1643. It is in a thriving condition, and bears a black fig. Gerrard says, "the fig requires a hot-wall," and Parkinson, that they are planted in great square tubs, to be removed into the sun in the summer time, and into the house in winter. The culture of the fig was little known here till the time of Miller, who introduced above a dozen new sorts from Italy. He observes, that the generality of Englishmen are not lovers of this fruit, and that, therefore, few trouble themselves with the culture of it. Since Miller's time, the fig has been introduced to the forcing department, and there cultivated to a much higher degree of perfection than before on open walls; and though it be still true, that a taste for the fig in its green or fresh state is less prevalent in England than elsewhere, yet, by those who have been some time abroad, it is generally much esteemed.

4840. Moneck "believes the fig-tree to be of all the fruit-trees which we cultivate in our gardens, the least understood; but, to those who may have acquired a knowledge of its habits, the most tractable. No tree is propagated more easily. I sent from London in April last to Kelsay in Northumberland, two cuttings of figs. They were so small as to travel by the post in a common letter-cover. I have gathered this year from one of them three ripe figs, and two from the other. The fig-tree may be checked in its useless habit of luxuriant growth by ringimg, so as to become fruitful at a very small size. It may be forced by heat and liquid manure, with copious irrigation, so as to support an abundant crop of fruit, and bring them to perfection, to a greater extent than any other tree. Spare branches of a large fig-tree growing out of doors may be ringed, and surrounded by a small pot of earth, into which they will speedily strike root, so as to bear being separated in autumn from the tree; and they may be used to furnish any glass houses with trees to bear fruit through the next summer. I believe, too, that the fig-tree may be easily propagated by inoculation, if that should be desired." \( (Hort. Trans. v. 179. \)

4841. Use. It is cultivated here entirely for the dessert; but in fig-countries it is eaten green or dried, fried or stewed, and in various ways, with or without bread or meat, as food. Abroad the fig is introduced during dinner, as well as at the dessert.
In common with the melon, it is presented after soup; and the person who cuts a fig, holds it by the small end, takes a thin circular slice off the large end, and then peels down the thick skin of the fruit in flakes, making a single bonne bouche of the soft interior part. All the species of the genus Ficus have more or less the quality of intermenging animal fibre, like the pawpaw-tree (Carica papaw); the F. elastica in the greatest degree, and next, the common fig. The milky sap may be used as rennet, and for destroying warts. Philips says, "a gentleman who lately made the experiment, assured me that a haunch of venison, which had lately been killed, was hung up in a fig-tree when the leaves were on, at about ten o'clock in the evening, and was removed before sunrise in the morning, when it was found in a perfect state for cooking, and he adds, 'that in a few hours more, it would have been in a state of putrefaction.'" (Pom. Brit. 169.) Burying in the soil for ten or twelve hours is a well known and effectual resource for internering recently killed fowls, or tough butcher-meat.

4842. Varieties. These, in fig-countries, are almost as numerous as those of the grape; new sorts being readily procured from seed, and continued by cuttings, layers, or grafting. Bosé says, that even in France new sorts are continually produced, and as quickly falling into neglect. The varieties most esteemed in England are the following: those marked with * will ripen as standards under favorable circumstances.

*Brown chestnut-colored ischia (island of Ischia). This is one of the largest that we have; it is of a brown or chestnut color, with dark black and white stripes, and red within; the grains are large, and the pulp is white, and somewhat coarse. It ripens in August; and if planted against a hot-wall, two crops may be obtained annually.

Black Genoa fig. This is a long fruit of a dark brown color, the flesh is of a bright red, and the flesh was unsalable. It ripens in the latter end of August.

Small white early fig. (Langley Pom. t. 52.) The skin of this fruit is of a brownish pale yellow when ripe; the flesh is white, has the odor of honey, and ripens in the latter end of August or beginning of September.

Large white Genoa fig. (Poll. of Torr. Fr. t. 4.) This is a large fruit, the skin is thin, and almost white when ripe, and red within. It is a good fruit, and ripens in the latter part of August. This and the preceding bearers are very common.

Black ischia. This is a middle-sized fruit; the skin is almost black when ripe, and the inside of a deep red. The flesh is high-flavored, and the trees good bearers.

Green ischia. This is a large fruit, of a light brown color, and the inside nearly of the same color as the flesh is well formed, and it ripens in the middle of September. This sort was introduced into this country by Mr. Murrey, of Chippenham.

Green ischia fig. This is an oblong fruit with a green skin; but when ripe it is stained through of a brownish cast by the pulp when full ripe. The inside is purple, and the flesh is high-flavored. It is ripe in the middle of September. This was introduced about the year 1820 by Mr. W. Ashley, of Newburyport, Mass.

Madonna, Brunswick, or Hanover fig. This is a large pyramidal fruit; the skin is brownish yellow, and the flesh brown, coarse, and has but little flavor. It ripens about the middle of September.

*Small blue or purple fig. (Daham. h. 4.) The fruit is dark purple, and very sweet. It ripens in August, and is a good bearer.

Common blue or purple fig. (Pom. Brit. 169.) The skin of this fruit is of a dark brown color; when ripe; the flesh inclining to red. It has large grains and a good flavor, and ripens the beginning of October.

Long brown Naples fig. The skin of this fruit is of a dark brown color; when ripe, the flesh inclining to red. It has large grains and a good flavor, and ripens the end of September.

Small black ischia. This is a small pyramidal fruit; the skin of a light brown; the flesh of a purple cast, and of a high flavor. It ripens in October.

Yellow ischia fig. This is a large fruit; the skin yellow; and the flesh purple and well flavored. It ripens in October.

Gentile fig. This is of a middle size; roundish; the skin yellow; the flesh inclining to the same color. It has large grains, and a good flavor. It ripens very late; and the trees are but indifferent bearers.

4843. According to Forsyth, the figs proper for a small garden are the

Large white Genoa Early white Murrey fig Small brown ischia Black ischia.

4844. Sawyer recommends for a regular succession of figs from August to October, inclusive, the

Brown ischia, Large white Genoa, Green ischia, Brown Naples, White Marseilles, Black Province, Yellow ischia, and Gentile; which ripen in the order in which they are here placed, from the middle of August to the end of October.

4845. Propagation. Figs may be propagated from seed, cuttings, layers, suckers, roots, and by ingrafting; the most generally approved method is by layers or cuttings, which come into bearing the second, and even the first year.

4846. By seed. Here the same process as that directed for raising seedling vines is to be followed, with this difference, that the young plants should not be cut down on account of their mode of bearing. They will produce fruit in the sixth or seventh year. The process of crossing to obtain new varieties can here be performed only in the general way, by crossing two or more sorts together; or of introducing a small hair pencil the pollen from the father variety, to take effect in conjunction with that of the male blossoms in the plant destined to bear seed. Possibly, however, some curious horticulturist may find a mode of cutting out the male blossoms without destroying the females; in which case the pollen from the father variety may be introduced to take effect alone. Lee, of Hammermith, has raised several new sorts from seed.

4847. By cuttings. These are formed of young wood from eight inches to twelve inches in length, with an inch or two of old wood attached. They shall be taken at the fruitful, well matured, and, if removed from the frost till spring, or planted in pots or in a bed of earth from six to nine inches deep, without cutting off their tops. The soil should be a loam inclining to sand, and in a warm situation; it should be covered with old bark, leaves, or ashes, to keep out the frosts in spring, and the drought in summer. If the cuttings have been planted in autumn, then their tops will require the additional protection of haum or litter during winter. Give water and keep clear of weeds, and during the following autumn, the plants will be fit to be transplanted into nursery rows; where they must be again mulched at root, and protected at top. They require no pruning farther than the shoots are required to rear them with a single stem, and keep their heads of a regular shape; the second or third year they may be removed to where they are finally to remain in the soil. Cuttings of roots readily make plants, but the process is too slow for general use, and the plants so produced are not likely to come to so soon into bearing as by layers or cuttings.

4848. By layers. This is the quickest mode of getting bearing trees, as shoots of two or three years' growth, if laid down, will make abundant roots the first summer, and admit of being taken off and placed where they are finally to remain in the autumn. Miller says, "young shoots or suckers produced from old shoots should never be taken, as they are too soft and spongy, liable to be affected by frost, and not likely to prove good bearers."

4849. By suckers. This is an easy, but a bad method, for a common reason, that all trees raised from suckers are subject to send out great quantities of suckers again from their roots, which branches are neither compact and fruitful, but too luxuriously to be ripened in our climate. Miller says, "this with a vicious habit, contracted while the trees are young, may be afterwards corrected."
4850. By grafting. This mode can only be advantageously adopted in cases similar to those recommended for grafting the vine. (4813) The process by any of the modes readily succeeds, and we have seen in Italy above a dozen sorts of figs on one tree.

4851. Culture. For the culture of the fig in the Forcing Department, see Chap. VII. Sect. V. In the open air, the plants are grown as espaliers, espaliers, and against walls; but, as already observed, the fruit produced in any of these situations is of very inferior flavor to that grown under glass. A crop of figs, Miller observes, is generally more uncertain than that of any other fruit: and Neill says, Britain is certainly not the country for figs. From the attention now paid to this fruit, however, by some eminent horticulturists, we may hope for improvement, and, at any rate, for a more general taste for the fruit.

4852. Soil. The fig-tree thrives in all soils not wet at bottom; but they produce a greater quantity of fruit upon a strong loamy soil than on dry sandy ground, a dry soil being apt to make them coast their fruit. The fig-tree bears the greatest quantity of well-flavored fruit which were growing upon chalky land, where there has been a foot or more of a gentle loamy soil on the top. They also love a free open air; for although they will shoot and thrive very well in close places, yet seldom produce any fruit in such situations. Smith (Caled. Hort. Mem. vol. ii.), after trying several sorts of figs, says, that the first season his trees were in fruit, produced a rich friable fig.

4853. Growing the fig as standards. In fig-countries, this tree is always grown as a standard; and here dwarf standards, planted in very warm situations, will, in very favorable seasons, afford tolerable crops of fruit. Some of the best in England are at Arundel Castle, and there is a figure of 100 trees at Taurine, and another of 14 at Topping, near Worthing. (Hort. Trans. vol. iv. 265.) Those at Arun- del are planted six or eight feet apart, and from a single stem allowed to continue branching into regular conical heads; pruning chiefly irregular and redundant growths, and cutting out decayed or injured wood. Miller observes, during winter, when the figs are nearly sized during winter, when the figs are nearly sized; which, however, may be considered as in great part owing to the mode of training and pruning figs in the latter situation not having then been generally considered. At Argenturré, where the fig is cultivated in immense quantities for the supply of the table, the plants are grown as dwarf standards; and the chisels are receiving the fruits in heaps in boxes, in large rooms, and in the open air, and they enjoy both the heat of the sun and reflection of the earth. The ground is manured occasionally, and stirred at least once a year; and for protection from the frost during the winter, the circumferential low branch is trained into the wall, and the central branch cut short in length. (4854. On espaliers. Where figs will succeed as standards, they will also thrive against espalier-rails, in which situation they admit of being more readily covered or protected during winter. The plants may be placed at ten or twelve feet distance, and trained in the fan or horizontal manner.

4855. On espaliers. In this situation, if the best mode of protecting the plants during winter, and is more likely to bring the fruit to maturity in the summer or autumn. The distances at which the plants are placed will depend on the height of the wall. In general, a low wall will be more suitable for figs, both because of the heat it imparts, and also on account of its lower temperature in the winter, when it admits more readily of protection. The plants may be placed from fifteen to twenty feet apart, with temporary trees of the fig, peach, or any other fruit between.

4856. Mode of bearing. "The fig-tree," the Hon. W. Wickham observes, "is distinguished from most, if not from all other kinds of trees, by this singular and extraordinary circumstance, that it always produces fruit the first season after having been transplanted, or even set from a seed; and, from within the first year to maturity, in every year, two successive and distinct crops of fruit, each crop being produced on a distinct set of shoots. The shoots, formed by the first or spring sap, put forth figs at every eye, as soon as the sap begins to flow again in July and August. These figs (which form the second crop of the year), ripen, in their native climate, during the course of the summer; but, rarely, if ever, come to perfection in England, where, though they cover the branches in great abundance, at the end of that season, they perish, and fall off, with the first severe frosts of winter. The shoots, formed by the second flow of sap, commonly called midsummer shoots, put forth figs in like manner at every eye, but not until the first flow of sap in the following spring. These last mentioned figs, which form the first crop of each year, ripen, in warmer climates, during the months of June and July, but not in this country before September or October. In warmer climates, indeed, very little attention is given to this first crop, because the midsummer shoots, commonly called the burnish of the fig, is not esteemed as good as the spring fig. The latter, however, is never equal to, nor can it compare with, the former, which is always larger, and in the same proportion. But in England, it is the reverse. As no care or skill of the gardener can induce the second set of sweet figs in the spring to ripen in the spring.

4857. Pruning and training. Most gardeners, Miller observes, imagine that fig-trees should never have much pruning; or, at least, that they should always be suffered to grow very rude from the wall to some distance. A pruned fig-tree never bears, is a common saying, nor, according to Wickham, can its truth be denied. The method of cutting off the long and unsightly, or the most coarse and method of cutting them; i.e. by cutting away or shortening the last year's shoots, instead of cutting away old wood, and training those shoots to the wall in its place.

4858. Wickham recommends a system of pruning which may increase the proportion which the midsummer shoots (the only ones, as stated above, which produce fruit that ripens in this country), bear to the spring shoots, both in number and length. For this purpose, he breaks off the spring shoots as they attain their full growth, and just as the spring sap in each begins to abate something of its full vigor. He breaks the shoot when six inches, or the distance between six inches and a foot, when the shoots are at their place whence they severally spring, taking care that enough of the shoot be left to admit of its being bent back, and nailed close to the wall at the ensuing winter pruning, and that one eye, at least, be left uninjured by the fracture, and always preserving a quantity until broken, sufficient to keep up a future supply of new growth. The shoot is not cut off neither broken, or left stumpy by a cut, but with a sharp instrument, such as the knaps of those of the most elegant workmen, which may afterwards be separated with a knife, when the spring sap has ceased to flow. The former mode is less unsightly, and will therefore be generally preferred by the gardener; but the latter has been more successful in practice. It is of consideration, however, to the full success of this system, that the shoots should be broken and not cut off. If left to their natural growth, or shortened by a sharp smooth cut with a knife (instead of a fracture), they would produce, at their extremities, only one single midsummer shoot, being a simple prolongation of the wood, formed in the spring; but when the shoot is broken at the time, and in the manner above described, it generally happens that, on the second flow of sap in July, two or three more shoots (forming a kind of stag's horn) are pushed from the fractured part instead of one; and it is hardly necessary to add, that each of these, according to its length, produces an equal series of shoots; and the great number of the first crop of these shoots is capable of being ripened by our ordinary summer and autumn heats. A sufficient supply of midsummer shoots being thus procured during the summer, room must be made for them at the succeeding winter pruning, by cutting away so much of the old wood as will admit of their being all trained in, at full length, and fastened to the wall, which shall always be cut off flush with the wall. As an object in view, the knife cannot well be used too freely in cutting away the old wood, nor is there any reason to fear that its free use will either injure the future crops, or deprive the tree of its regular supply of branches. The midsummer shoots being trained in, each of them will produce, in the following
one spring shoot, at least, at its extremity, whilst another will rise from each eye of the remnants of the old spring shoots that had been preserved in the manner above described; when these shoots were 4 or 5 inches long, by this free treatment of the plant, either wood or fruit, or both, may be obtained for the succeeding year, at the discretion of the gardener. Where he wishes for wood, he must suffer these new shoots to grow to their full length: where fruit, and not wood, is desired, he must break them in the month of June, in the manner and with the precautions minutely described above. (Hort. Trans. vol. 74, p. 669.)

Knight disapproves highly of training the branches of fig-trees perpendicularly, as encouraging too much the prolongation of the shoots; he approves of Wickham's mode in warm situations, but in high cold situations, it radiates his branches from the top, and parts near it, of a single stem. He says, “as we propose to use a narrow and gradually diminishing wall, and from the top, and parts near it, of this, let lateral branches be trained horizontally and pendently, in close contact with the wall. Under such treatment, all troublesome luxuriance of growth will soon disappear, and extend them more than is necessary. Young shoots, only extend enough to fill the wall, and the fruit being in contact with the wall, and not shaded by excess of foliage, acquires an early and perfect maturity.” (Hort. Trans. vol. iii. 307.)

The Rev. G. Savary, from the various papers on the culture of the fig-tree, published in the Horticultural Transactions, but particularly from that of Wickham, infers, “that the principal defect requiring a remedy is a deficiency of fruitings, or bloom, in the early spring, on the whole of the last year's shoots, excepting on the few joints at their extremities,” and he describes a remedy which he has for a long time been in the habit of using, and which he “considers as a specific.” It is simply to rub off, as soon as they can be discovered by the naked eye, all the figs which are produced after midsummer on the same year's shoots. The object is not only to prevent those figs which would never ripen without artificial heat to exhaust the tree, but to give sufficient time to employ the strength which would have been employed in nourishing these “sterilising incumbrances,” in the seasonable preparation of new embryo figs for the following year. “If this operation,” he says, “be performed in due time, it will not fail to prepare on one, and often on both sides, of almost every fig so displaced, such embryos. For this purpose, the tree should be examined once a-week, from the beginning of August, at which time the figs of this second crop will be very easily distinguished by their immaturity, and may be removed, and thus the lessened luxuriance of the tree will make their appearance.” Most gardeners, he says, omit removing these late figs at all, or delay the practice till October or November, when no benefit is derived from it. He trains the trees horizontally, and does not prune them till late in the spring, when he plainly distinguishes between a leaf and a fruit-bud, as well as appreciate the whole of the mischief occasioned by the frosts of the preceding winter. (Hort. Trans. vol. iv. 430.) The above practice, in connection with the mode of training recommended by Knight, would, we think, effect an important improvement in the culture of this fruit. Wickham's mode appears to excite too much fruiting in the tree; and too much of the tender and succulent nature of the young shoots, on four or root-stems, which are in fact so many suckers, is only calculated to produce wood and leaves. Training the fig-tree on walls, as a rider, and in the stellate manner (fig. 386, c), and pinching off all the embryo fruit after midsummer, would probably effect every thing that can be desired in the culture of this tree on the open wall in this country.

4851. Protecting during winter. This is found necessary in many parts of France, and every where in Britain. Recommendations tending together the branches of standards, and applying pease-haulm, straw, or any other light covering; rolls of reeds to be placed on each side of espaliers, removing these coverings in mild weather, to prevent the figs from coming out too early. Forsyth covers fig-trees against walls with “laurel, yew, fir, or spruce boughs,” and then “tucks in short grass or moss among the branches.” Smith covers with spruce fir branches, from three to six feet long, fastening them to the wall by the middle rib of the branches, at two different places. “To prevent any friction by the wind, the branches should be made to fit each other, that the covering may be of a regular thickness over every part of the trees. As the covering is generally put on the trees in the month of December, the branches remain green all the winter; and in the month of March, when the days get long, the leaves begin to drop from the branches, and continue falling through April; and by the beginning of May, when the covering is entirely removed, only the ribs of the branches are found remaining. Thus, the progress of the season reduces the coverings in a gradual manner, so as not to expose the trees to any sudden check, which might otherwise be the case, if they were all at once laid open to the weather.”

4852. Savary, in November, detaches the branches of his fig-trees from the walls, picks off all the autumnal fruit that are larger than a filbert, or not of a dark shining green; he then ties the branches of the tree together in bundles forming a sort of cones, filling the interstices with dry hay, and wrapping mats round them. He then ties the lower limbs of the tree together, and ties the stems fast to the wall with rope-yarn. In this state they remain till March, when the wall is undisturbed, and the branches are replaced and covered first with treble, then double, and lastly single netting, which last is removed in May.

4853. Mean (Hort. Trans. vol. ii.) adopted the French mode of burying the branches in the soil, in 1789, and has since practised it with success.

4854. Wickham observes (Hort. Trans. iii. 80.), in respect to covering fig-trees, that “much must be left to the care and skill of the gardener, whose precautions must be determined, as well as varied, by the situation, aspect, and local shelter belonging to each particular tree, and by the varying temperature of each particular part of the tree, however it may happen that the covering should be thinned out and the covering down as the general weather will require it. The covering must be as thin and light as a due consideration of all the above circumstances will admit, and that it should generally be removed in the day-time, and always on the return of moderate weather.

4855. Willimott, in his treatise on the production of figs, states that the practice of removing a circular ring of bark from the lower part of the branches of the fig, in the manner he has so successfully practised on the vine, might accelerate the maturity of the fruit. Monck tried ringling, and found that it may be practised on the fig-tree with “as much safety, and more effect upon the age of its fruit than on the pear-tree.” (Trans. Travels, vol. iv. p. 172.) This method is to cut as much of the bark from the young fruit's with olive-oil. In Italy, a wound with a knife is sometimes made on the broad end of the fig, or a very small part of the skin of the fruit removed for the same purpose. Brandy is also sometimes applied, either by a puncture on the side of the fruit with a bodkin dipped in the spirit, or by dropping a small quantity in the eye of the fruit. “Plums and pears,” Tournfort observes (Trans. letter, viii.), “pricked by incision open the faster for it, and the flesh round such puncture is better tasted than the rest. It is not to be
puted but that considerable change happens to the contexture of fruits so pricked, just the same as to parts of animals pierced with any sharp instrument." Monck splits a fig from the eye to the stalk, and found it ripen six weeks before others that were untouched. (Hort. Trans. v. 172.)

4867. Monck has made some curious experiments and observations on this subject, from which he is led to conjecture, 1. That fig-trees never bear figs which contain both kinds of florets in an efficient state; 2. That figs in which the anther-bearing florets only are perfect, never come to be 'eatable fruit; 3. That you may pronounce, from the external shape of a fig, which kind of floret prevails — the stigma-bearing in the squat figs (fig. 507, a), the anther-bearing in the long figs (b); 4. That fig-trees, which put forth crops of figs, and cast them, most probably do so from defect of setting. (Hort. Trans. v. 168, 169.)

4868. Insects and diseases. The fig is subject to few of either of these in this country. In forcing-houses it is liable, in common with other plants, to the attacks of the red spider, coccus, and aphides, and occasionally also on garden-walls. The remedies are obvious. In France they are attacked by a species of coccus, vulgarly called the fig-rove, which proves very injurious, and is only to be destroyed by rubbing them off with a little white sand.

4869. The melon is a tender annual, producing one of the richest fruits brought to the dessert, and cultivated in England since 1570; but the precise time of its introduction, and the native country of the plant, are both unknown. It was originally brought here from Jamaica, and was, till within the last fifty years, called the musk-melon. The fruit, to be grown to perfection, requires the aid of artificial heat, and glass, throughout every stage of its culture. Its minimum temperature may be estimated at 65°, in which it will germinate and grow; but it requires a heat of from 75° to 80° to ripen its fruit, which, in ordinary cases, it does in four months from the time of sowing the seed.

4870. Varieties. There are numerous varieties, many of which, especially those raised from seeds brought from Italy and Spain, are not worth cultivating. The best sorts are included under the name of cantaloupes, an appellation bestowed on them from a seat of the Pope near Rome, where this variety is supposed to have been originally produced. The general character of the cantaloupes is a roundish form, rough, warty, or netted outer coat; neither very large in fruit or leaves. The Romanas, the Italian sort, next in esteem, are generally oval-shaped, regularly netted; the fruit and leaves middle-sized, and the plants great bearers. Many varieties of both these sorts, however, that were formerly in esteem, are now lost, degenerated, or supplanted by others of Spanish or Persian origin. The following are among the best of both the old and new varieties:

The early golden cantaloupe. It is deep-furred, middle-sized, longish, golden colored; flesh not very high-colored nor high-flavored. The plant grows freely, shows early, sets its fruit well; and is a very good bearer.

The orange cantaloupe. Smaller than the golden-cantaloupe. The flesh, when just fit for it, is orange; but when ripe, it is more yellow. When ripe, it becomes partly netted. In respect to flavor, it is excelled by none of the melon kind; being juicy, sugary, and rich in flavor. It is, however, an early sort, and a great bearer.

The netted cantaloupe. This is equally juicy and highly-flavored, as the last-mentioned; a good deal larger, round, solid, and very perversely; having a very small vacuum for the seeds; and it may be eaten nearer to the rim than most other kinds. The plant sets freely and is a good bearer.

The silver cantaloupe. Round, of a middle size, shallow-furred; and when full-grown, before it begins to color, is all over mixed silver and green. It is very good bearer.

The black cantaloupe. This is a very large-growing melon; round, black, or very dark green when full grown; yellow when ripe. It is very juicy, but not so high-flavored as any of the above cantaloupes, except the first-named; nor is the plant so good a bearer. Four or five fruit in a light is a medium crop.

The carabinched rock cantaloupe. Two varieties; a large and a small; both very similar to the black rocks, as to color and flavor; but flat or cheese-shaped, and covered with large protuberances or carabins. The small kind bears pretty freely, and the large sort less so.

Lev's rock cantaloupe. Rather long than round, and more green than black. The flesh and flavor much the same as those of the last-mentioned variety.

The Italian green-flushed cantaloupe. Small, nearly globe-shaped; usually about four inches and a half in diameter coat pale greenish-white, moderately thin; flesh opaque, soft, and melting; in flavor both rich and sweet. (Hort. Trans. iv. 210.)

The smooth scarlet-flushed cantaloupe. Round or oval, with a red or bright greenish-yellow, with fine white verrucose reticulations; flesh nearly an inch and a half in thickness, of a uniform bright scarlet from the edge of the coat to the centre, and tolerably firm; it is particularly high flavored. (Hort. Trans. iv. 303.)
The montagu cantaloupe, is a variety produced from the two last named sorts; intermediate in size between them; greenish-white without; the flesh an inch and a half thick, very high colored, but soft and juicy, completely melting in the mouth, and with a very sweet and delicate flavor. (Hort. Trans. iv. 123.)

The green-flushed Ionian cantaloupe, lemon-colored and lemon-shaped; large, thin-skinned, a great bearer, and does not readily mature seeds, but of excellent flavor. (Caled. Mens. iv. 210.)

The green-flushed Egyptian melon. Medium-sized, round, nectared; in habits and flavor resembling the last-named variety. (Caled. Mens. iv. 210.)

Loch. Melons, long, slender, with long stalk; shallow-furrowed, solid, and ponderous; flesh white, thick, with pale-yellow; flesh a full yellow, pretty high-flavored, but not very juicy.

The large netted romana. The largest of all the netted melons; netted all over, shallow-furrowed, oval, solid, and very large, 16 to 18 inches in length, nine or ten pounds in weight. Rind hard, pale-yellow when fit to cut; the flesh a full yellow but not very juicy.

4871. Choice of seed. In the cultivation of the melon, Knight observes, it is a matter of much importance to procure proper seed. Some gardeners are so scrupulous on this point that they will not sow the seeds unless they have seen and tasted the fruit from which they were taken. It is proper not at least to trust to seeds which have not been collected by judicious persons. Some make it a rule to preserve always the seeds of those individual specimens which are first ripe, and even to take them from the ripest side of the fruit. A criterion of the goodness and probable fertility is generally sought by throwing them into a vessel containing water; such as sink are considered as good and likely to prove fertile, those that float, as effete. It is remarked of seeds brought from the continent, that they must have more bottom heat, and the young plants less water, than are necessary for seeds ripened in this country, or young plants sprung from these.

4872. For the entire course of culture of the melon, see Chap. VII. Sect. VII.

4873. The cucumber is a tender annual, a native of the East Indies, and introduced in 1573. It is a trailing and climbing plant, with large roundish rough leaves, furnished with tendrils, and if sown in the open air in May, produces flowers from July to August. The cucumber is of nearly as great antiquity as the vine, for Moses, the earliest Jewish author, mentions it as abounding in Egypt, when the children of Israel were there, above three thousand years ago. (Numbers, chap. ii.) In England it is cultivated generally and extensively, in forcing-frames and in the open air, and especially near large cities and towns. “Not only gentlemen,” as M‘Phail observes, “but almost every tradesman who has a garden and dung, have their cucumber-frame.” In Hertfordshire, whole fields are annually seen covered with cucumbers without the aid of dung or glass, and the produce of which is sent to the mercantile for pickling. In March, cucumbers fetch in the London market a guinea a dozen; in August and September, fifteen a dozen. The village of Sandy, in Bedfordshire, has been known to furnish 10,000 bushels of pickling cucumbers in one week.

4874. Use. The green fruit is used as a salad; it is also salted when half-grown; and preserved in vinegar when young and small. In Germany and Poland, barrels of half and also full grown cucumbers, are preserved from one year to the other; by immersion in deep wells, where the uniform temperature and exclusion of air seems to be the preserving agents.

4875. Varieties. The principal of these are —

The early long prickly; from five to seven inches in length, with few prickles. The plant is a good bearer, and upon the whole, this is accounted the best cucumber for the general summer crop, the pulp being very crisp in the mouth. (Hort. Trans. 1829.)

Longest green prickly; from seven to ten inches in length, in dark green skin, closely set with small prickles. This is a hardy sort, but does not come Early short prickly; not more than four inches long; the skin green, rather smooth, but with a few small black prickles. This is one of the hardest and earliest sorts, and is often preferred for the first crop.

Dutch white short prickly, though not much cultivated, is recommended by some, as preferable even to the early long prickly; it has fewer seeds; it is evidently different in taste from most other cucumbers, but of agreeable flavor. (Hort. Trans. 1829.)

Cluster cucumber; a very early sort, the flowers appear in clusters of three or four together; the fruit is seldom more than four inches long; is a soft melon of a fine green color, but becomes yellowish as it ripens. The stems of this variety are much inclined to climb by means of their tendrils upon sticks; the leaves are small, and the plant altogether occupies but little room.
Sow a portion in a warm border, and the main crop in an open compartment. Dig the roundly or nearly round, 10-inch line with intervals of five or six feet; and in the lines mark stations three and a half feet distant; then, with a towel at each of these spots, form shallow circular sower-corn cavities in the surface, ten or twelve inches wide, and about an inch deep in the middle. Sow in the middle of each cavity eight or ten seeds, half an inch deep. When the plants are come up, and begin to put forth the first rough leaves in the centre, thin them to three or four of the strongest in each hole. Earth these up a little, between and close round the stems, pressing them a little asunder; and give them some water, to settle the earth below and above. In their advancing growth, train out the leading runners. Supply them with requisite waterings, in dry weather, two or three times a week, or sometimes every day in very dry hot weather, in July, August, or September. At this season, water early in a morning, or late in the afternoon, towards evening.

57. Gathering. — The crop comes in sometimes towards the end of July, but more generally not before August in full production; and about the middle of or end of September, when the plants decline. Be careful to gather the fruit in a prime state, both for pickling and other purposes. They must be quite young for pickling, not exceeding two or three inches in length. (Abercrombie.)

SECTION II. Exotic Fruits, well known, but neglected as such.

4878. Among neglected exotic fruits we include the orange tribe, one of the most beautiful, and also, a very useful class of fruits. The culture of oranges and lemons for the table is not at present common in England; but, in our opinion, it might be pursued with much enjoyment to the amateur, since, independently of the gratification of seeing fruit of one’s own growth at the dessert, no object of the fruit-tree kind can be more splendid than a large healthy orange-tree covered with fruit. The pomegranate seems also to merit culture, both for its singular beauty while on the tree, and the addition it would make to the dessert.

4879. Of the genus citrus there are five species or leading sorts, of which the fruit are used; all natives of Asia, viz., the common orange, the lemon, the citron, the lime, and the shaddock. The common character of the plants bearing these fruits is that of low evergreen trees, with ovate or oval-lanceolate, entire or serrated, leaves. On the un-gathered trees are often axillary spines. The flowers appear in peduncles, axillary or terminating, and one or many flowered. The fruits are large berries, round or oblong, and generally of a yellow color. The species seem best distinguished by the petiole, which, in the orange and shaddock, is winged; in the lemon, lemon, and lime, naked. The form of the fruit, although not quite constant, may also serve for a distinction. In the orange and shaddock, it is spherical, or rather an oblate spheroid, with a red or orange-colored rind; in the lime, spherical, with a pale rind; in the lemon, oblong, rough, with a nipple-like protuberance at the end; in the citron, oblong, with a very thick rind. The flowers of the citron and lemon have ten stamens, and those of the orange more. Professor Martyn observes, that it is very difficult to determine what is a variety, and what is a species in this genus. The trees in the eastern countries, where they are natives, vary in the size and shape of the fruit and leaves; and many of those considered varieties in Europe, preserve their differences in their native woods. He has no doubt that any one who would pursue this subject in the native countries of these fruits, would detect varieties connecting all those generally considered as species. This opinion appears highly probable when we examine the catalogues of the continental writers on this fruit; who, in general, finding it difficult to make botanical distinctions, are obliged to rest satisfied with popular descriptions. In Nouveau Cours, &c. art. Oranger, those cultivated in France, and in Dr. Sickler’s work, and that of Gallesio, those of Italy, are so described.

4880. Dr. Sickler, who spent several years in Italy, and paid great attention to the kinds and culture of the orange, published in 1815, Der Vollkommnen Orangerie-Garten (The Complete Orange-Gardener), in which he describes above seventy sorts of citrus, including all the species above mentioned. He arranges the whole in two classes, and these classes into divisions and subdivisions, without regard to their botanical distinctions or species, thus: —

The names and some descriptive traits of these seventy-four sorts of citrus will be found in *A Short Delineation of Dr. Sickler’s Treatise*, by Dr. Noehden, in the *Hort. Trans.* vol. iii. App.

4881. *Gallesio (Traité du Genus Citrus, &c. Savonna, 1818.*) has given a synoptic tree, in which he has introduced ramifications which display an arrangement of the forty principal sorts cultivated in Italy.

4882. *The most splendid work on oranges which has yet appeared* is the *Histoire Naturelle des Orangers*, by Risso, of Nice, and Poiteau, of Versailles. (Paris, fol. 1818.) Here 169 sorts are described, and 105 of them figured, and their French and Italian culture given at great length. They are arranged as sweet oranges, of which they describe 43 sorts; bitter and sour oranges, 32 sorts; bergamots, 5 sorts; limes, 8 sorts; shaddocks, 6 sorts; lumes, 12 sorts; lemons, 46 sorts; citrons, 17 sorts.

4883. *All the species of citrus endure the open air at Nice, Genoa, and Naples*; but at Florence and Milan, and often at Rome, they require protection during the winter, and are generally placed in conservatories and sheds. The largest conservatory in Italy is that of Prince Antonio Borghese, at Rome, which contains seventy select sorts of *agrumi*. The largest trees are at Sorenta, Teracina, Gaeta, and Naples; but the most regular and garden-like culture of the orange, is in the orange-orchards at Nervi, Monaco, and other places in the neighborhood of Genoa. At Nervi are also the orange-nurseries which may be said to supply all Europe with trees; they are, in general, wretchedly cultivated, and the stocks inoculated in the most unscientific manner; but the fine climate, strong clayey soil, and abundant manurings, supply in a great degree the nicer practices of gardening. There the names of varieties vary as much as those of gooseberries do in England; but from upwards of one hundred names, not above forty distinct sorts can be procured. Good plants of the Maltese and other varieties of orange may be procured from Malta; and some sorts also from Lisbon. From the nurseries
at Paris about thirty sorts may be obtained, much smaller plants than those from the other places named, but more scientifically grafted or inoculated. At Vallet’s nursery at Rouen, is a collection of very large plants of the common kinds. The catalogues of London nurserymen enumerate above thirty varieties of orange, twelve of lemon, and several varieties of the other species; the plants are generally inoculated, and small, and are more provided for pots than for planting in the soil for producing fruit. As being most useful for the British horticulturist, we shall place under each species the names of the varieties which may be procured in England.

**4885. The orange-trees of Beddington, in Surrey, introduced from Italy by a knight of the noble family of the Carewes (Gibson’s edit. of Cult. Brit.), were the first that were brought into England; they were planted in the open ground, placed under a movable cover during the winter months, and they had been growing there before 1295. It has been said, that these trees were raised by Sir Francis Carew, from seeds brought to England by Sir Walter Raleigh; but as such trees would not have rooted in the colder climate, Professor Martyn thinks it much more likely that they were plants brought from Italy. Bradley says, they always bore fruit in great plenty and perfection; that they grew on the outside of a wall, not nailed against it, but at full liberty to spread; they were fourteen feet high, the girth of their trunks twenty-nine inches, and the spreading of the branches one way nine feet, and twelve feet another. These trees, Evelyn informs us, were neglected in his time during the minority of their owner, and finally entirely killed by the great frost in 1739-40.**

4886. *During the latter part of the seventeenth and beginning of the eighteenth centuries, the orange-tree was a very fashionable article of growth in conservatories, when there were but few exotics of other sorts kept there. The plants were procured from Genoa, with stems generally from four to six feet in height; they were planted in large boxes, and were set out during summer to decorate the walks near the house in the great European conservatories. At about the middle of the eighteenth century, when a taste for botany and forcing exotic fruits became general, that for superb orange-trees began to decline; many of these large trees have decayed through neglect; and those which are now to be found in the greater number of green-houses, are generally dwarf plants bearing few fruit, and those of small size; in some places, however, are still to be found large and flourishing trees. Those at Smorgony in Glamorganshire, are the largest in Britain; they are planted in the floor of an immense conservatory, and bear abundantly. It is said that the plants were procured from a wreck on the coast in that quarter, in the time of Henry VII.*

4887. At Nuneham, near Oxford, are some very fine trees, planted under a moveable case, sheltered by a north wall. In summer, the case is removed, and the ground turned over, so that the whole resembles a native orange-grove. At Wormleybury, Hertfordshire, and Shipley Hall, in Derbyshire, are very fine orange-trees in borders and in conservatories. (Hort. Transact. vol. ii. 259, and IV. 506.)

4888. At the Wilderness, Kent, (Marquis Camden’s,) are three trees in boxes, not surpassed by any trees so grown in Europe. C. Bingham, at Isleworth, possesses a very fine collection; and various others might be enumerated.

4889. At Boddall, near Hamilton, trees of all the species of citrus are trained against the back wall of forcing-houses, in the manner of peaches, and produce large crops of fruit.

4890. *In the south of Devonshire, and particularly at Saltcombe, one of the warmest spots in England, there are orange-trees, in a few gardens, that have withstood the winter in the open air upwards of a hundred years. The fruit is as large and fine as any from Portugal. Trees raised from seed, and inoculated on the spot, are found to bear the cold better than trees imported.*

4891. *Use. As a dessert-fruit, the orange is well known. The varieties imported, which are most esteemed for this purpose, are the China, Portuguese, and Maltese. It is also used in confectionary, both ripe, and when green and not larger than a pea: it forms various liquors and conserves, either alone or with sugars, wines, or spirits; and either the pulp or skin, or both, are used for these purposes. In cooking, it is to stomatitis a number of dishes. The juice of the Seville orange is used in medicine, in febrile and inflammatory disorders; and that of the other sorts possesses the same qualities in a lesser degree. The acid of orange, Dr. Cullen says, unites with the bile, takes off its bitterness, and may prove useful in obviating disorders arising from its redundancy and acidity. In perfumery, the orange is used to prepare perfumes and pomades; and the flower, of the same kind, tinctured, produces orange-water, used in cooking, medicine, and as a perfume.*

4892. Varieties. *These are very numerous in the eastern countries, and even in Italy and France. About forty sorts are cultivated in the neighborhood of Paris, and about thirty in the London nurseries, of which we shall give a list. The principal varieties are the sweet, or China orange, the orange dauce of the French, and porta-gallo or pomme de sano of the Italians; and the bitter or Seville, the bigarade of the French, and arancio volgare of the Italians. The Maltese orange, distinguished by its red pulp, is also a noted and much-esteemed sort. The box-leaved, willow-leaved, and some others, are cultivated more as curious varieties than for their fruit.*
PRACTICE of GARDENING. Part III.

4893. The Citron is the C. Medica, L. (Gar. fru. 2. t. 121, f. 2.); the citron of the French; the citronier of the Germans; and cedrate of the Italians. (fig. 512.) In its wild state the tree grows to the height of about eight feet, erect and prickly, with long reclining branches. The leaves are ovate, oblong, alternate, sub serrate, smooth, pale green. The fruit or berry is half a foot in length, ovate, with a protuberance at the tip. There are two rinds, the outer thin, with innumerable miliary glands, full of a most fragrant oil; the inner thick, white, and fungous. The citron was introduced into Europe from Media, under the name of malus medica, and was first cultivated in Italy by Palladius in the second century. The date of its introduction into England is not exactly known; it would probably be coeval with that of the lemon, which was cultivated in the botanic garden at Oxford in 1648. The fairest fruit, Miller states, was in the Duke of Argyle's garden at Whitton, where the trees were trained against a south wall, through which there were flues for warming the air in winter, and glass covers put over them, when the weather began to be cold. Thus the fruit was as large and as perfectly ripe, as it is in Italy or Spain. In Italy citrons and lemons are generally trained on walls or espaliers, because, being considerably more tender than the orange, they require, at least in the north of Italy, some protection in winter; the fruit does not ripen regularly at one time, like that of the orange, but comes successively to maturity almost every month in the year.

4894. Use. The fruit is seldom brought to the dessert in a raw state, but it forms excellent preserves and sweetmeats, to furnish the table when other fruits are scarce. The juice, with sugar and water, forms lemonade, a most refreshing, salubrious, and universally esteemed beverage. Its use in punch and negus is well known. It is much used in medicine, and also in perfumery and dyeing.

4895. Varieties. Dr. Sickler enumerates only about a dozen citrons and citronates as grown in Italy. The French nurseries have nearly twenty names in their lists. In England the six following are cultivated for sale:—

<table>
<thead>
<tr>
<th>The common citron</th>
<th>The rough-fruit</th>
<th>The grape-fruit</th>
<th>The round-fruit</th>
</tr>
</thead>
<tbody>
<tr>
<td>The flat-fruit</td>
<td>The forbidden-fruit</td>
<td>The grape-fruit Barbades</td>
<td>The round-fruit</td>
</tr>
</tbody>
</table>

4896. The lemon is the C. Medica, var. Limon, W. (Blackw. 592.); the limon of the French; limonier of the Germans; and limone of the Italians. (fig. 513.) The distinction between the lemon and citron is very trifling. The fruit is less knobbled at the extremities, is rather longer, and more irregular, and the skin is thinner than in the citron; the wood is more knotty, and the bark rougher. Cultivated in the Oxford garden in 1648.

4897. The uses of the lemon are the same as those of the citron.

4898. Varieties. Dr. Sickler enumerates twenty-eight as grown in Italy. The French, according to Ville Hervé, have eleven sorts; in the London nurseries are cultivated the twelve following:—

<table>
<thead>
<tr>
<th>Common</th>
<th>Pear-shaped, or Lime (fig. 514)</th>
<th>Striped silver</th>

</table>
4899. The time in the Citrus Acidum, Rox. (Brown's Jam. 396.) by some esteemed a variety of the C. Medica; the time of the French, Italians, and Germans. (fig. 515.) The sour lemon, or lime, grows to the height of about eight feet, with a crooked and thorny twisted drilized branches, with prickles. The leaves are ovate, lanceolate, almost entire. Berry an inch and a half in diameter, almost globular, with a protrubance at the top; the surface regular, shining, greenish-yellow, with a very odorous rind, enclosing a very acid juice. It is a native of Asia, but has long been common in the West Indies, where it is grown both for its fruit and juice.

5000. The uses of the lime are the same as those of the lemon, to which, in the West Indies, it is preferred; the juice being reckoned more wholesome, and theacid more agreeable to the palate.

5001. Varieties. By the catalogue in Nouveau Cours, &c. the French have two sorts of lime; and according to Dr. Sicker, the Italians have four varieties. The following five kinds are known in the London nurseries:

The common lime
The weeping
The Italian lime
The Chinese spreading.

5002. The shaddock is the C. uccumanus, W. (Temp. am. 2. t. 24. f. 2.) the orange pampelmouse of the French; and the arancio massimo of the Italians. (fig. 516.) The tree is above the middle size, with spreading prickly branches. The leaves are ovate, subacute, seldom obtuse; the petioles are cordate, winged; the wings as broad as the leaves. The berry sphericaloid, frequently retuse at each end, of an even surface, and greenish-yellow color; pulp, red or yellow; juice, sweet or acid; rind, white, thick, fleshy, and bitter. Thunberg says, the fruit in Japan grows to the size of a child's head, and Dr. Sicker states its weight as fourteen pounds, and its diameter as from seven to eight inches. It is a native of China and Japan, and was brought to the West Indies by Captain Shaddock, from whom it has derived its name. From the West Indies it was sent to England, and cultivated by Miller in 1739.

5003. Use. The shaddock is certainly the least useful of the species enumerated, and is cultivated chiefly for show. It has the handsomest leaf of the whole tribe, and the fruit is larger than the orange. Where several sorts of oranges are presented at the dessert, it makes a striking addition to the variety. The juice is of a subacid sweetness, and excellent for quenching thirst; and the fruit, from the thickness of its skin, keeps longer in sea voyages than any of the other species of citrus.

5004. Varieties. The Italians, according to Dr. Sicker, have one; and the French, according to the Nouveau Cours, &c. four sorts. The following four are grown in the English nurseries:

The common shaddock | The rough-fruitcd | The largest-fruitcd | The West India.

5005. Propagation of the citrus tribe. All the sorts may be propagated by seeds, cuttings, layers, and grafting, or inoculation.

5006. By seed. The object of raising plants from seed is either to obtain new varieties or stocks for grafting. To attempt raising new varieties in Britain will in general be found a tedious process, as the trees do not even in Italy show fruit for six or eight years or more; and there is now in the botanic gardens at Toulon, a large handsome tree, over twenty years growth, which had not in 1833 flowered. However, if new varieties are attempted, select the largest and best-formed ripe fruit of the kind to be raised, extract the seeds, dry them, and sow and nurse as hereafter directed for raising stocks. Where trees are to be raised for stocks to bud oranges, Miller advises to procure citron-seeds, as stocks from the same are preferable to any other for quickness of growth; and as they will take buds of either orange, lemon, or citron. Next to these are the Seville orange seeds; and the best of either sort are to be had from rotten fruits. Prepare in spring a good hot-bed of dung or man, and when it is in moderate temper sow the seeds in pots of light earth; plunged them, give water frequently, and raise the glasses in the best of the day. In three weeks the seeds will come up, and in a month's time be fit to transplant into single pots. Then renew the bed, and fill pots of five inches in diameter half full of good fresh earth, mixed with very rotten cow-dung: shake out the seedlings, and plant one in each pot, filling it up with the same earth, and replunge as before. Give a good watering at the roots, and repeat this often, as the orange tribe in a hot-bed require a good supply of water. Shade in the day-time, when the sun is powerful, and give air so as not to draw the plants. By this method, with due care, the plants will be two feet high by July, when they must be hardened by degrees, by taking the glasses off a high and eddying; in fine days, taking them entirely off, shading the plants from the sun with mats or other screens. Towards the end of September, house them in a dry part of the green-house, near the glass, where they will not be liable to damp off. During winter refresh them with water, and in April now and then wash their stems and leaves, to clear them from any filthy matter they have contracted. Place them again in a moderate hot-bed, and harden them by the beginning of June, that they may be in a right order to bud in August.

5007. Budding. Make choice of cuttings from trees, that are healthy and fruitful, observing that the shoots are round; the buds of these being much better and easier to part from the wood than of such shoots as are flat or angular. After performing the operation, remove the plants into the green-house, or under glass frames, to defend them from wet, turning the buds from the sun; but let them have as much free air as possible, and refresh them often with a mixture of water. In about six months it will be observable which has taken, then untie them, and let them remain in the green-house all the winter. In spring cut off the stocks about three inches above the buds, and place them in a moderate hot-bed, giving air and water, and shading as before. By the end of July they will have made shoots of two feet or more; then harden them before the cold sets in, that they may the better stand the winter; and in the first winter after their shooting, you must keep them very warm, for by forcing them in the bark-bed they will be somewhat tenderer; but it is very necessary to raise them to their height in one season, that their stems may be straight, for in trees which are two or more years growing to their full height, the stems are always crooked. In the succeeding years their management will be the same as for full-grown trees.

5008. The Italian process of raising and budding. In the orange-nurseries at Nervi, 3 D
the seeds of the citron or orange, as it may happen, are sown in beds in the open ground in February or March, and in September planted out in compartments, in rows generally about eighteen inches wide, and the plants six or eight inches in the row. They are placed thus close to draw them up with clean straight stems. There they remain generally four years, and in April or May of the fifth year they are taken up, their roots cut within four or six inches of the tap-root, which is also shortened to six or eight inches, according to the size of the tree. The stem, if it has any side shoots, is pruned clean, and sawn off horizontally, at such a height as that the section is from half an inch to an inch in diameter. (fig. 517. a) The general heights are one foot, which forms the lowest-growing plants; eighteen inches for trees to be sold in Italy; from two to four feet for trees to be sent abroad; and five or six feet for extraordinary orders. These last are not so common; as the stocks require six or eight years' growth, and some care to attain that height with clean stems, and a diameter of three quarters of an inch. The plants thus pruned are budded, sometimes when out of ground, and sometimes after planting. One bud is inserted on each side of the stock (a), within an inch of the section. In a month buds and roots begin to push, and in December or January following these plants are in fit state for taking up for exportation. After being taken up, the roots, now well furnished with fibres, are enveloped in a ball of stiff clay; this is covered with moss carefully tied on, and in this way they are laid in boxes, or in casks, and sent not only to most parts of Europe, but to North and South America.

The chief defect in this system is the naked horizontal section at the top of the stem (a), which, not being smoothed with the knife and covered with clay or any other protection, to cause the bark to grow over it, indurates and cracks with the drought; retains moisture and decays, so that in almost all trees that have been budded in this way, a dead stump or a rotten hole, may be observed during the whole period of their existence. This evil is often lessened by covering with a cap of lead or a patch of wax; but it might readily be obviated by peeling off a piece of bark from one side of the part of the stock to be sawn off (d), letting it remain attached to the lower part or stem; and after removing the head, bringing it down close over the section, inserting its end under the bark in the opposite side, somewhat in the manner of saddle-grafting; or the manner employed by surgeons in amputating a limb (e) might be adopted. A similar object might probably be effected by removing a wedge-shaped section from the top of the stock (f), and then compressing its sides, so as to present a wedge-shaped termination covered with bark (g). But the gardeners at Nervi are too indolent and obstinate to hear of any thing new, and will persist in their present plan till the credit of Genoa for orange-trees is gone, or till some strong necessity urges them to improvement.

5909. The Maltese, aware of the defects in Italian trees, make a sloping section (b), paring it clean, and budding on one side only; the consequence of which is, that the section becomes covered with bark, and, which it never does in the Italian method, as sound and healthy as any part of the stem. The French grafted in a very neat manner (c), and indeed their orange-trees, though small, are much handsomer than the Italian ones.

5910. By grafting. This mode is occasionally resorted to in Italy, and is that most generally adopted in the gardens in Paris. The stocks, when of two years' growth, and not much thicker than the scion, are cut over within six inches of the ground, and then grafted in the whip manner. The trees continue small, but have clean stems of from one to three feet, and generally make handsome plants, profuse in flowers and fruit, of a small size. Grafting, both by the whip manner and by approach, is frequently practised in England, in nearly the same circumstances of age, size, and effect, as practised in France. A variety of the whip-manner is described by Cushing, in which the top of the stock is left on, but the scion is cut off as in grafting. "Form the scion as for the common whip-graft, and then, without taking off the head of the stock, cut from the stem an equal splice as smoothly as possible; do not tongue the scion, but tie it on neatly and firmly with matting and clay, in the manner of a graft: plunge them in a hot-bed, and cover with a cap-glass till the scion begins to grow, and then cut away the top of the stock, and remove the matting by degrees." (Exotic Gard. 103.)

5911. Whip-grafting in the common way has lately been successfully performed, even with fruit or flowers on the scion, by Nairn, who gives the following account of the process: "Let the operator select as many orange or lemon stocks as he wishes to work, and place them on a moderate hot-bed for a fortnight, by which time the sap will have risen sufficiently to move the bark; the stocks must then be cut off, about two inches above the surface of the pot, and an incision made with a sharp knife, similar to what is done for budding, separating the bark from the wood on each side. Let the scion be cut thin, in a sloping direction, and thrust between the bark and wood, and then bound tight with woollen yarn; but very great care must be taken in binding, to prevent the bark from slipping round the stock, which, without attention, it is very apt to do. After it is properly and neatly bound, put a little loam or clay
close round the stock, to the surface of the pot, then, with a glass of a proper form (fig. 518), to prevent the damp from dropping on the scion, cover the whole, and press it firmly into the mould, to prevent the air or steam from getting to the plant; the glass must not be taken off, unless you find any of the leaves damping, and then only till this is remedied, when it must be immediately returned. The stocks must next be placed on a brisk hot-bed of dung, and in about six weeks, the glasses may be taken off, and the clay and binding removed. Basing will be necessary to bind on a little damp moss, in lieu of the clay, and to keep the glasses on in the heat of the day, taking them off at night; when, in about three weeks or a month, they will be fit to be put into the green-house, where they will be found to be one of the greatest ornaments it can receive. I should recommend the mandarin orange for the first trial, as the fruit is more firmly fixed than that of any of the other sorts. I have, by the above method, had seven oranges on a plant, in a pot, commonly called a small sixty, which I conceive to be both curious and handsome." (Hort. Trans. iii.)

5912. Henderson's mode of grafting is well adapted for proving successful.

"Take two-year-old wood, cut into lengths of about seven inches, (fig. 516 a), cut a piece out of the stock of a triangular figure, about an inch and two eighths in length, regulating the depth according to the thickness of the graft, and keeping it square at the bottom. Displace two leaves at the bottom of the graft, for the convenience of getting it put on, cut the graft right across under one eye, where a leaf has been taken off: dress the graft to fit the receptacle made in the stock, observing to keep the lower end of the graft equal in thickness as above; always let three or four leaves remain untouched on the graft. After the graft is fitted in the stock, tie it up with bass matting, and put clay around it. If the grafts and stocks are nearly of the same thickness (b), cut the stock, at right angles, nearly half through. Cut off the piece, keeping it equal at top and bottom: cut the lower end of the graft right across under an eye (c), and with a knife prepare the graft to fit the stock. When the grafted plants are tied up and clayed, set them at the back of the vineyard or peach-house, observing to keep them away from the flies, as fire-heat is hurtful to them at first: cover them with hand-glasses, or, if a frame can be spared, it is still better. Shade them every day, but take the mats off at night; continue the shading till they begin to grow, when they may be exposed to the light. If any stock happens to be so tall and thick that it cannot be placed under a hand-glass or frame, put two or three grafts on it, set in any convenient place in the house, and shade it with mats; it will succeed perfectly in this way, the grafts lose none of the old leaves; and, in five or six months, they will make three or four young shoots six or eight inches long; these, with the leaves that were on the grafts when put on, form a well-clothed little plant."

5913. By cuttings. This method, though little practised on the continent, where the object is large trees and fine fruit, is frequently adopted by the British gardener, whose object is generally small handsome plants. Two methods are adopted: the first is to take young succulent wood as soon as it has done growing, and the lower end has become somewhat mature. These cuttings, prepared properly (5914) are inserted with a small dibber in pots of light sandy loam, with two or three inches of gravel or broken pots at bottom. They are then covered close with a crystal bell, and plunged in a gentle heat, and shaded. The glasses are taken off only to wipe them when damp, and to remove any decaying leaves. In two months such cuttings either strike or rot off. The second method is in spring to take the shoots of last year; to prepare and plant them as above; but after covering them with glasses to plunge them in a cold-frame, where they remain in a state of apparent inaction for three or four months, when they either form a callous mass, or come out at the lower end of the cutting and push at top, or die off. After preserving them in a low temperature through the winter, they are placed the succeeding spring in a gentle hot bed, where they will push freely, and make tolerable plants. The success of either mode may be facilitated by taking care to place the cuttings so as their ends may touch the bottom of the pot, or the potsherd or gravel with which that is covered. The advantage of so placing cuttings is generally known to gardeners, and has been noticed by Hawkins in the Hort. Trans. vol. ii. p. 12.

5914. Henderson considers cuttings as the quickest mode of getting plants, and has practised it for thirty years past, and his directions are as follows: "Take the strongest young shoots, and also a quantity of the two-year-old shoots; these may be cut into lengths from nine inches to eighteen inches. Take the leaves off the lower part of each cutting to the extent of about five inches, allowing the leaves above that to remain untouched: then cut right across, under an eye; and make a small dibber in an angular direction on the bottom of the cutting. When the cuttings are thus prepared, take a pot, and fill it with sand; size the cuttings, so that the short ones may be all together, and those that are taller in a different pot. Then, with a small dibble, plant them about five inches deep in the sand, and give them a good watering overhead, to settle the sand about them. Let them stand a day or two in a shady place, and if a frame be ready with bottom heat, plunge the pots to the brim. Shade them well with a double mat, which may remain till they have struck root; when rooted, take the sand and cuttings out of the pot, and plant them into single pots, in the proper compost (see Pl. 183). Plunge the plants in the young growth and shade them for four or five weeks, or till they are taken with the pots; when they may be gradually exposed to the light. From various experiments, I found that pieces of two-year-old wood struck quite well; and in place, therefore, of putting in cuttings six or eight inches long, I have taken off cuttings from ten inches to two feet long, and struck them
PRACTICE to but "because with for two so is injurious enter appearance.

the trees are laid or when they are put into single pots, and taken with the pots, they are grafted with other sorts, which grow freely. I am not particular as to the time either of striking cuttings for grafting." (Cited, P. H. H., iii. 306.)

5915. By layers. This mode is occasionally practiced both on the continent and in England. At Monza, near Milan, there is a very fine collection of lemon-trees in boxes, trained as espaliers, which were raised. The trees are five feet high, and each box has a portion of trellis attached to it of that height, and ten or twelve feet in breadth, and the whole covered with a trash or layering of earth, either be laid on their sides, and laid as stools, or pots may be raised and supported under the branches. These branches, or their shoots of one or two years' growth, may then be laid on the ground, and bent down through the hole in the bottom, and treated in the usual manner, taking care to supply water with the greatest regularity. They are covered in March, which will be fit to separate from the stools as mother plants in the September following. In general, it may be observed, that the citron tribe, like other fruit-bearing plants raised from cuttings or layers, though they may prove very useful to the trees, yet seldom grow with that vigor, and produce such large fruit, as those propagated by budding or grafting on seedling stocks.

5916. Soil. At Genoa and Florence they are grown in a strong yellow clay, which is richly manured; and this soil is considered by the first Italian gardeners, as best suited to their natures. At Rome and Milan the natural soil is lighter. When this is adopted generally, a very strong age is not the most suitable in the garden of his Holiness the Pope. At Naples, where the trees are always planted in the open ground, the soil is lighter and of volcanic origin. A strong soil, in imitation of that of Nervi, is recommended and adopted by the Dutch. (See Van Oster, Nich., Hesperides, &c.)

5917. The French gardeners, according to Bose (in N. Cour. Agr. in loco), in preparing a compost for the orange-tree, endeavor to compromise for quantity by quality; because the pots or boxes in which the plants are placed ought always to be as small as possible, relatively to the size of the tree. The following is the recommended compost for a fresh plant as a third of handsome horse-dung, and a third of vegetable matter, and which has lain in a long time in a heap, an equal bulk of half-rotten cow-dung. The following year turn it over twice. The succeeding year mix it with nearly one half of decomposed horse-dung. Turn it over twice or three times, and the winter before using, add a half of cow-dung, a twelfth of dried cow-sand, and a quarter of lime.

5918. Miller says, the best compost for orange-trees is two thirds of fresh earth from a good pasture, and one third of neat's dung. These should be mixed together at least twelve months before using, turning it over once a month, to mix it well and to rot the sward. Pass it through a rough screen before using.

5913. M'Phail and Abercrombie recommend "three eighth of cow-dung, two third of cow-dung, two thirds or three years; a fourth part of vegetable mould from tree-leaves; one sixth part of fine rich loam; and one twelfth part of road-grit; to this may be added one eighth part of sheep-dung." (G. Rem. 242. Pr. Gard. 774.)

5920. Moss has tried the following mixture (Hort. Trans. ii. 205), and with which he has "every reason to be satisfied. Well-prepared rotten leaves, two to three years old, one half; rotten cow-dung, two, three, and four years old, one fourth; mellow loam, one fourth; with a small quantity of sand or river-sand, to be sifted over the compost, which is not to be left out."

5921. Agnes, who grows excellent table fruit of the citrus, at Shipley, uses ten parts of strong turflaam, seven of pigeon-dung, seven of garbage from the dog-kennel or butcher's yard, seven of sheep-dung, seven of good rotten horse-dung, and ten of old vegetable mould, mixed and prepared a twelvemonth before using. (Hort. Trans. iv. 180.)

5922. Henderson, of Wood Hall, a most successful cultivator of the genus citrus, gives the following directions as to soil: "Take one part of light-brown mould from a ground of that has not been cropped nor manured for many years; one part of good earth, such as is used for growing hothalets; two parts of river-sand, or pit-sand if it be free from mineral substances; and one part of rotten hot-bed dung; with one part of rotten leaves of trees. Mix them all well together, so as to form a compost-soil of uniform quality." (Cited, Hort. Mem. iii. 502.)

5923. Temperature. The standard temperature for the citrus tribe is 48°; but in the growing season they require at least ten degrees of additional heat to force them to produce luxuriant shoots. The air of the house in which the plants are kept, whether in boxes or in the ground, should never be allowed to fall under 40°, for though the orange, like the pine-apple, will endure a severe degree of cold for a few hours without injury, there is danger of the leaves being injured if the temperature be allowed to recover their appearance. Ayres never suffers his orangery to be heated above 50° by fire-heat, until the end of February; when the trees show blossom, it is increased to 55°, but never allowed to exceed 60° by sun heat, which has a deleterious admission of atmosphere, and sometimes when he "begins to force the trees, by keeping the heat in the house up near as possible to 75°. For I do not consider (he adds) that either citrons, oranges, lemons, or limes, can be grown fine and good with less heat." (Hort. Trans. iv. 511.)

5924. The orange, Humboldt observes (De Distrib. Plant. 138.), which requires an orange temperature of 64° for a degree of cold, if continued only one quarter of an hour.

This is proved by an observation of Dr. Sickler, who says, "It is remarkable how much cold and snow the common lemons and oranges will bear at Rome, provided they are planted in a sheltered situation, not much exposed to the sun. Thus I saw in the two winters of 1805 and 1806, under my window, on Monte Pincio, three standard orange-trees in the open ground, heavily covered with snow for more than a week. The green leaves, but still the more golden fruits, nearly ripe, looked singularly but beautiful amid the snow; neither fruits nor trees suffered, being in a sheltered place, while many branches and leaves were in severe exposure to the wind, and it did not snow in such depth as to strike the whole tree sickly." (Folk. Oron. Gart. 5.) It appears that the snow had been thawed off these trees gradually, and more by the temperature of the atmosphere than by the direct rays of the sun, or a current of heated air. This resulted from their sheltered and partially shaded situation; and, as Dr. Norden (Hort. Trans. iv. 180) observes the trees are much more exposed to the sun and wind, if it be more the sudden transition from cold to heat, and the contrary, than the degree of either, which destroys vegetables. Whenever orange-trees or any tender exotics have been touched during night by frost, they should either be immediately shaded by mats from the next day's sun, or thawed by water at not more than 22° or 23° of temperature. In northern regions the same treatment is successfully applied to animals. (See Hort. Trans. iii. 42. and 144.)

5925. Water. Orange-trees, like other evergreens which delight in a strong soil, are not naturally fond of water. Nevertheless they want a much lighter one than the pot or box; but still it is necessary that the earth be constantly moistened occasionally with a little water; for the earth being indurated, the water only reaches the surface, and runs over and escapes by the sides of the pot or box; so that while the mass of earth below is dry, the surface has a sene moist appearance. Mein says, "When I think from the appearance of a plant, that the water does not freely enter into the earth, I follow the plan red, about the base of the trees, and give every three days, putting it to the bottom of the earth, and to form a channel for the water, too little or too much of which is equally injurious to orange-trees." Knight (Hort. Trans. ii. 239.) watered an orange-tree with very strong liquid manure, and found it, in a few hours, caused a fine vigorous root to the vine and mullbery. Ayres, after the fruit is set, watered it with water, in which, at the rate of three barrows of fresh cow-dung, without litter, two barrows of fresh sheep's droppings, and two pecks of quick lime have been added to every hogshead; when
used, the water is about the consistence of cream. (Hort. Trans, v. 310.) The French water once after shifting with a very strong leesive; they also mulch with recent cow and horse droppings, renewing these once a-month or oftener during summer, that there may be always abundance of soluble matter for the water to convey to their roots. (Nouveau Cours, etc. art. Orange.) McPhail mentions a case in which very large orange-trees in the border of a conservatory looked sickly; when, on digging deep into the borders to examine the cause, he found the earth quite dry, and by afterwards continuing to water them regularly he recovered them. (G. Rem. 342.)

5925. Air. During the winter season, Miller observes, orange-trees require a large share of air when the weather is favorable; for nothing is more injurious to these trees than stifling them. The prevention of damp, Mean observed, is as essential to the perfection of the plants as the exclusion of cold. Where these trees are kept in old-fashioned opaque-roofed green-houses, these cautions as to air and damp deserve particular attention. Ayres says, the more air orange-trees have during the blossoming season, the more certain will they be of setting the fruit.

5926. Light. Many gardeners are of opinion that the orange tribe do not require so much light as other exotics, which may have arisen from the gloomy conservatories in which they used to be formerly kept during winter; for certainly to look at the orange-houses at Versailles and Kew, one would not conclude light to be a very essential requisite. But though these trees, like other evergreens, when in a state of maturity, will live with less light than evergreen or deciduous plants in a growing state, they always suffer for the want of it, which is indicated by the paleness of the leaves in spring, and by their falling off when set out in the open air and fully exposed to the influence of day. Whoever intends to grow the orange in any degree of perfection, should adopt houses, if not with glass on all sides, at least with glass fronts and roofs. When the plants are placed in the naked ground as standards, glass on all sides is highly desirable; for otherwise their leaves and shoots will all be turned to the south, and the north side of each tree will in a short time become naked and unsightly.

5927. Manner of growing the trees. All the species may either be grown as dwarfs in moderate-sized pots or boxes; as standards with stems from two to six feet high in large boxes; as standards planted in the naked ground; and either as dwarfs or standards planted and trained against a wall or trellis under glass. The two first modes are more adapted for ornament than producing crops of large fruit; for all the art of the gardener will never make plants grow as vigorously in boxes as in the free ground. Standards planted in the free ground or floor of the conservatory, combine both elegance and utility; as in a house properly constructed, they will make handsome heads, and produce abundant crops of fruit. The last mode, or that of planting against walls or trellises, is much the most certain way of having large crops. Every part of the plant above ground can thus be brought near the glass and equally exposed to the sun's influence and that of the air and heat: they can be more readily pruned, and correctly trained, watered, and washed; and they occupy less room in proportion to the produce. The trees at Wood Hall, in West Lothian, some of those at Shipley, and at some places in Devonshire, are trained in this way. In a very few favorable situations in the South of England, as at Gerston and Woodville, in Devonshire, they are trained against walls in the open garden.

5928. Plans for orange-houses. These must naturally depend on the mode of growing. For plants in moderate-sized pots and boxes, a common green-house is the obvious habitation; for, being plants of ornament, they require merely the treatment of that department. The conservatories in Italy have generally opaque roofs, but some of the more enlightened nobles of Lombardy have lately erected splendid constructions with glass roofs, in which they combine the culture of the citron tribe with other, large-growing exotics. (Fig. 692.)

5929. For trees in large boxes, a proportionally large and lofty house is requisite; it may be opaque on the north side with a glass roof, front, and ends, of any convenient or desired length, width, and height. For one of moderate size, the height at the back wall may be fifteen feet, at front ten feet, and the width of the house fifteen feet. The floor may be either perfectly level, and the boxes placed on it, the largest behind, so as their tops may form a slope to the front glass, as in the conservatory of Prince Borghese, at Rome; or if the trees are young, a stage may be erected for a few years, in order to raise the plants to the light: but if the trees are of a considerable size, the best way is to have square pits in the floor at regular distances, somewhat larger than each box, and in these to sink the boxes, covering them with
mould, sand, or moss nearly to the level of the pavement, so that each tree so placed and dressed, will appear as if planted in a small compartment of earth. Such is the plan of the large avenue in which the royal gardens at Versailles. The effect is the same no matter what is planted in the front of the house, with corresponding doors in each end; but where the trees are young, and placed on a stage like green-house plants, the walk should be in front, as in no other situation could the eye of the spectator meet the foliage of the plants. Where the walk is in the middle, and a double row of trees on each side as at Monza, the effect in small gardens is truly magnificent and gratifying.

5930. Where the trees are to be planted as standards in the borders or floor of the house, it is essentially requisite to the health and beauty of the building that the glass be glazed on all sides. (fig. 524.) Showers might be supplied in Lodidge's manner; heat by steam pipes in the beds (6) might be covered with turf, strewn with daisies, violets, and primroses; these would come early into flower, and if the turf were kept very short about the roots of the flowering plants, and the trees in excellent condition, only those who have not the first-rate, might not be able to form an idea of the effect, which, by contrast with the external winter, would be felt as luxurious and as anticipating real spring.

5931. Where orange-trees are to be trained against the back wall or a trellis, under the glass, the forms adopted for common houses in the island are perfectly suitable; but as by training close under the glass, is done with vines, much of the beauty of the foliage would be lost, training on a trellis a few feet distant, with a path between it and the glass, is preferable.

5932. Plans for tubs, pots, and boxes. Unglazed pots of earthenware are preferable to glazed stone ware or China, as the form need not be separated from that in common use, and the size must depend on that of the plants. At Florence, where the largest and best garden-pots in Europe are made, the rim and part of the outside of pots destined for oranges and ornamental plants, are often decorated with festoons of flowers or fruit, and lions' heads, or other elegant ornaments; which some plants now often have begun to imitate. One advantage of tubs is, that by unhooking them, the staves are instantly removed, and the roots examined and dressed, and by having a cooper at hand they are immediately replaced; thus saving much of the trouble necessarily incurred in shifting plants in pots or boxes.

5934. Boxes. All boxes which are larger than the largest-sized pots, should be contrived to take pieces, in order to examine the roots, or to shift into larger boxes. Square boxes held together by an iron hoop, and taking to pieces on the principle of tubs, are most generally used for trees which do not require more than five or ten cubic feet of earth; and such as are used at the Tuilleries and by Mean (figs. 177 to 179) answer very well for plants requiring from ten to sixty cubic feet. Those of Mean contain sixty-four cubic feet of compost.

5935. Proportioning the size of boxes to that of the plants. The general opinion of gardeners is in favor of small pots or boxes; and where the object is dwarf plants, or merely to preserve the trees without much increasing their size or regarding their fruit, they are the most proper. But where the object is luxuriance of growth and fruit, it does appear to us that the pots or boxes cannot be too large; unless, as Van Osten observes, it is meant merely to prevent the roots from being crowded together, or the plants from growing large and strong. It is, however, expedient to pot at first in small boxes, and remove into larger ones by degrees. The largest boxes in use in Holland and France are four feet square, which serve for trees with stems from six to eight feet high, with globular heads of six feet in diameter, and above a century old. Henderson has "always found that the luxuriant tribe, and plants in general, grow best in pots or boxes, regarded as rather small in proportion to the size of the plants." (Caled. Mem. iii. 503.)

5936. Choice of sorts. Where the object is more ornament than fruit for the dessert, a selection may be made from the varieties of each species at pleasure; where the object is fruit for the dessert, the following sorts are to be preferred: the common, bloodystreaked, Bergamot, Maltese, sweet China, Seville, and Mandarin oranges; the common lemon, citron, and lime, and one or two plants of the shaddock. These include all the essential varieties of the orange tribe as far as respects fruit; variations in the leaves and mode of growth.

5937. Choice of plants. For moderate-sized trees to be treated like green-house plants, such as are raised in this country or in the Parisian nurseries are preferable; but where the object is large handsome trees in boxes, standards in the free soil, or trained trees, then plants from Genoa or Malta are decidedly preferable; indeed, no plants fitting for the purpose of standards could be elsewhere procured. Of this opinion, observing, that "by such the quicker way of furnishing a green-house with large trees, is to make choice of such as are brought over every year in chests from Italy; for those which are raised from seeds in England will not grow so large in their stems under eighteen or twenty years, as those are when brought over; and although their heads are small when we receive them, yet in three years, with good management, they will obtain large heads, and produce fruit." When the plants are purchased in London, at the Italian warehouses, without names, the greater number will be found to be either of the shaddock and citron kinds; as the Italian gardeners find these sorts make stronger shoots and more showy plants, and therefore send a less number of the less luxuriant but more useful varieties. But the best way is to send an order, through a British merchant who has a correspondent at Genoa, for named sorts, ordering so many of each class, either from the table of Dr. Sikkier (4880) or the synopsis of Gallesio. (fig. 4882.)

5938. Management in pots and boxes. The management of dwarf English or French plants in moderate-sized pots or boxes, for the green-house stage, consists in common green-house treatment. Being potted in the proper soil, the roots are to be annually examined before the growing season in spring, and when matted or diseased, trimmed off and repotted, or shifted into larger pots at discretion. Henderson says, "The general management of the orange-trees from the middle of March till the 1st of October, may be discussed in a few words. I give the trees a good watering all over the leaves once a week with the engine, excepting when they are in flower. Till the end of May this watering is given about 11 o'clock in the forenoon. After the end of May, I give them a good dashing over the leaves twice a-week with the engine, and now I do it in the evening. In very hot weather I repeat the engine-watering thrice a-week. Part III.
I never set the orange-trees out of doors during summer; for, from thirty-eight years' experience, I find it is much against them, in the climate of Scotland. In hot weather I keep them in the back of the vineyard, under the shade of the vines, or behind the stage of the green-house. Orange-trees delight to be in the shade in sunny weather; they here grow freely, and keep a fine dark-green color. From the frequent watering the leaves in hot weather the water, but they must be carefully attended to, and when the plants are making their young shoots, the pots or tubs require a good supply of water. From October to March, I give them a gentle sprinkling over the leaves once in two or three weeks, but only in fresh weather, taking the opportunity of a mild day, when there is a little sun, and always in the morning."

5939. For the management of Italian plants, destined to grow large trees and produce crops of fruit in boxes or tubs, the treatment requires to be more particularly detailed.

5940. The following are Miller's directions:—Having furnished yourself with a parcel of trees, prepare a moderate hot-bed of tanner's bark, in length and breadth according to the number of trees to be forced, then put your trees into a tub of water upright, about half of the stems, leaving the head and upper part of the stem out of water, the better to draw and imbibe the moisture. In this situation they may remain four days, which will render them sufficiently fit to be clean their roots from all fig, cutting off all broken or bruised roots, and all the small fibres which are quite dried by being so long out of the earth, and scrub the stems with a hard hair brush, cleaning them afterwards with a cloth; then cut off and throw away about six inches from the stems about three or four of the old earth, and laid in with very rotten neat's dung, plant your trees therein, observing not to put them into large pots; for if they are but big enough to contain their roots it is sufficient at first planting. Wrap the stems round with hay-bands from bottom to top to prevent the sun from drying their bark; plunge the pots in the dark-led, watering well to set earth to their roots, frequently replating the same all over their heads and stems, being very careful not to over-water them before they have made good roots, and shade from the sun in the middle of the day. If they have grown kindly they will have made strong shoots by the beginning of June; at which time you will find them in open borders, and be ready to admit them into the greenhouse, or at least to bring them out of the house about the second week of August, and during summer, water frequently but moderately, guarding against frost. In the following spring clean the stems and leaves of the plants, top-dress the earth, and mix the refuse of the sawdust, rotten, and care the earth in the green-house. Remove to a sheltered situation in the open air by the end of May. As the trees advance, stop strong irregular-growing shoots in the summer season, to force out lateral branches, to fill the head, and render it regular and free from weak trifling branches. The tree will require to be shifted and new-potted, every other year excepting the first, having removed lateral branches or trusses out of the house, and from the beginning of March, roots round the outside of the ball of earth, and take away all mouldy roots; then with a sharp iron instrument, get as much of the old earth from beneath the roots as possible; then set the root of the tree in a large tub of water, for about a quarter of an hour, then lift up, and have prepared to replant the stems. Keep the trees, and water, letting them remain in the house till they have taken root.

5941. The operation of shifting, when the plants become very large, is much facilitated by adopting the mode of being taken up in cases, as already described; the balls of earth can then be slid from one box to the other instead of being lifted out of the box. Where the boxes do not separate, the tree and ball must be lifted out by fixing one end of a rope to the stem of the tree, and passing the other over a pulley suspended from a triangle. This method is recommended in Van Overbeke's Hort. Micr. to prevent a common inconvenience, viz. the tree and ball of earth being thus, by either mode, suspended in the air, the latter is examined, the roots pruned, &c., and this done, the same or a larger box is placed directly below the ball, with a proper quantity of compost at the bottom, and into this tree is lowered, and the sides filled with earth, &c. The worst thing attending this mode is the liability of injuring the bark of the stem by the noise of the suspending rope.

5942. Henderson shifts oranges only once in two years, and frequently after a longer interval. "I never shift any plant till the pot is very full of roots. In shifting the oranges, I always take as much of the exhausted mould away as I can; and, on account of the light and free nature of the compost used, it comes easily from among the roots. The best season for this operation is about the beginning of March. Having turned the plants out of the pots or tubs, pick as much of the old exhausted mould from the ball as you can, without injuring the roots. They should be shifted into the pots or tubs only on the table being larger, and some of the plants will perhaps do better if replaced into the same pots again. Let the pots be all clean washed and dried before any plants be again put into them. Put a piece of crockery or broken pot over the hole in the bottom of the pot, with the convex side down; then compose the piece of crockery or broken pot over the hole, and close the same with earth, after which the stems are made from pit-coal, broken small, about the size of peas. This both forms a drain, and prevents the entrance of worms. On the top of the charred cinders place a layer of dried moss (lignum vitae), which prevents the compost mould from getting down, and lets in heat, and keeps the roots free from the effluvia of the stems of the plants. All the pots being prepared in this way, put in a little of the compost; then introduce the roots of the plant into the pot, and fill it up with the compost, observing to keep a little of the mould between the side of the pot and the roots. The plants may be set partly into the peach-house or pot-house, and some in the green-house, which will give a longer succession of their flowers. The orange-trees that are placed in the vineyard or peach-house, if there be any fire-heat used at the time, must be watered as soon as put in; but those put into the green-house where there is little heat, may stand a day or two without water. After that time they may be watered once a-week till the weather become warm, when they will require it oftener. Those placed in the vineyard or peach-house will require watering very frequently, according to the degree of heat kept in the house." (Caled. Hort. Mem. iii. 304.)

5943. Renovating old trees in pots or boxes. Where orange-trees have been ill managed, and their heads become ragged and decayed, Miller directs to restore them by cutting off the greatest part of their heads by March; drawing them out of the pots or tubs, and shaking off the earth from their roots; then cutting away all small fibres and mouldy roots; and next soaking and cleaning their roots, stems, and branches, planting them in good earth, plunging them in a hot-bed, and treating them as directed for trees received from abroad.

5944. Management of the citron tribe as standards. Prepare foreign plants as directed above, and instead of planting in pots, plant in the border or floor. This must have been laid dry by proper drains, and if on a wet sub-soil, flints, &c., to prevent them from penetrating into it. On this lay the roots in exactly the same manner, to the thickness of three or four feet; care having been taken in constructing the house, that all the walls (excepting the north wall, if the house be exposed on that side), flues, paths, &c., be supported on pillars or piers, so as the heat may escape; and compost may extend outside the circumambient air. Plant the trees either in squares, or better in quinconx, allowing six or eight feet between the trees, which will give thirty-six or sixty-four square feet to each plant. This distance will suffice for several years, and afterwards every other tree can be taken out. After planting,
which should be finished in April, water at the root, and morning and evening sprinkle a little over the tops to assist in causing them to break freely. Apply fires, and keep the house close night and day, with a moist heat of from 55° to 60° till the plants have made shoots of three or four inches; then begin to give air, by keeping up the fire still till the shoots are completed, when the sashes should be taken off to harden and color the shoots and leaves. It will be necessary to attend to the above directions annually, for three or four years, in the growing seasons, in order to procure as much wood in a short time as possible. Keeping the heads open and regular, with the consequent culture of all the other seasons of the year, the following benefits result:

5943. On walls and espaliers. Prepare the plants and the border as before, and plant about ten or twelve feet, allowing a larger space for the citron, lemon, and shaddock, than for the common orange, as they produce more of the growing shoots; in reserve the directions already given, continuing them annually. The manu manner of training is that generally adopted.

5946. Pruning. The French pay great attention to this part of the culture of the orange tribe; and, indeed, display greater art in pruning every sort of tree, than the British. They have their winter taille, and their different sort of pruning to increase the produce of the trees. In Versailles and the Tuileries are looked over every year, and receive a very elaborate pruning every sixth or eighth year. The object of this pruning is to keep the head proportioned to the capacity of the box containing the root. Without pruning, the trees would assume an entirely different form, and be subject to the indications of suffering for want of nourishment every sixth or eighth year. The shoots are then shortened to within an inch or two of the old wood, and the tree, thus almost completely deprived of leaves, does not produce blossoms during the two next years: it pushes, however, vigorous shoots, which are trained to form the two principal arms, and assist the bearing in the shape of a natural tree. Such was the line of espaliers, in the great garden of Versailles, made by the late M. Pethon, who was head gardener at Versailles for forty years. The form of the heads of the trees at Versailles is that of a cylinder, spreading out at top, of which the height is greater than the breadth; those in other places are ovate, globular, or mushroom-shaped, and some are even square and triangular. (See Van Osten, c. xi.) The blossoms of the orange-trees in the royal gardens of France, and in most gardens of Holland and the Netherlands are carefully picked off as they appear; as well to prevent the tree from being exhausted by bearing fruit, as for the use of the flowers in perfumery. Those of the Turkish and the Pomelo are gathered at the rate of 150 a-year, or, when large, 250 a-year, and produce 125 a-year, or upwards. In Holland the flowers are commonly the perquisite of the gardener. Thus the beauty of the continental orange-trees is far inferior to those of Italy or Britain, which are covered with fine large fruit.

5947. Gathering which the orange grows in England, does not differ, in general, from that given to any green-house tree or shrub; and the consequence is, handsome bushes or trees, with the blossoms and fruit on the surface of the foliage. But when the orange-tree is cultivated for fruit, whether as standards or against walls, the branches ought to be thinned, like those of other fruit-trees, so as to allow of the sun, air, and water, to bring the blossoms and fruit regularly distributed from the centre to the extremities. This is readily effected where the trees are flat-trained, which, where fruit is the object, is a great advantage in favor of that mode of culture.

Pest: For the present, I must be content to state, that the most useful blossoms of most sorts of citrus are produced in the form of terminating peduncles, on the wood of the current year; and hence, the grand object of the pruner ought to be to encourage the production of young wood in every part of the tree, by cutting out naked wood, and shortening vigorous shoots where wood is wanting. A powerful co-operation is also given to the expansion of the light on the young wood, when the blossoms are observed, is only to be done, in standing, by keeping the trees open, or by flat training. There are also blossoms produced by various sorts of citrus, in tufts, directly from the axils of the leaves of the wood of the preceding year; these expand earlier than the others, but generally drop off in plants which are not well managed; cover such plants withieling branches is a means of holding the branches together. In February, to make room for younger and more productive wood, and shorten very strong branches to keep the trees in proper shape. After the fruit is set, it ought to be thinned, seldom leaving more than one on a peduncle. In France they thin the flowers, which, by that means, are enabled to use for distillation. The thinned fruit is used in confectionary. Mean observes, "In regard to the necessity of thinning the fruit, lest the trees exhaust themselves, it appears to me to depend on the state of the trees: if they are flourishing, I never observed that it was at all required, either here or at Bromley Hill, where the orange-trees belonging to the Right Honorable Lord Nelson, are grown with peculiar success, laden with fruit; and there are about the size of green-gage plums, and never leave two fruit together. Will standard trees, pruned with a view to fruit, be equally beautiful with the compact geometrical-headed trees of Paris, and the old conservatories of this country? Those who prefer a full-bottomed head of fruit, and other effects of the hallowed old English authors, are of different kinds; the latter has utility to recommend it; the former, associations of the pomp and formal grandeur of past times. Quintinie, and other French authors, direct the wounds or sections made in pruning orange-trees, to be covered with a composition of charcoal and wood, to exclude the air; and it deserves to be attended to, as the growth of the bark is otherwise very slow over wounds in these trees.

5949. Mature. About Genoa, the best cultivated orange-groves are managed annually. In France and this country, the best practitioners stir the surface and apply a top-dressing of rich compost when the trees begin to grow, generally in April, top-dressing in a 1 to 3 years top dressing. In the Italian gardens, and those at Hieres in France, where the fruit of the orange is raised for sale, it is gathered every year, generally in May. If not then gathered, it will hang on the tree for one or two years longer; but when the young green and swelled fruit, and ripe becoms somewhat shrivelled, and if then gathered is found almost void of juice. But as the new fruit begins to arrive at maturity, the juice begins to return to the old fruit; so that both old and new crops are in perfection together the following May. In this way, at Genoa, the orange is sometimes allowed to remain on the tree two and three years, and, by being gathered here and there in succession, is sold at a very high price to connoisseurs at Milan, Turin, and other places. The lemon differs from the orange in that it ripens irregularly, and drops off when ripe. It is therefore gathered at almost every season. The orange-tree, kept in conservatories, generally requires fifteen months to ripen its fruit, and begins to bear fruit when about three years old. Some claim that the orange is the same variety as the grapefruit, and therefore of the same origin, but others state that it is derived from Santo Domingo; but Quintinie says, "on a vigorox plant they will remain three or four years. In Britain they often remain three years on moderately strong plants without fruit. In gathering the fruits, they cannot be pulled with the hand, but carefully cut off with a few leaves attached, and, thus garnished, sent to the dessert. By allowing them to hang two years, the trees will at all times have green and yellow fruit, which, in connexion with their shining green leaves and fragrant blossoms, forms, early in spring, in such a house as we have hinted at [5929. and fig. 521], one of the most splendid of horticultural specimens of the year.

5951. Insects and diseases. The chief insects injurious to the citrus tribe, are the coccus and red spider; both to be removed or destroyed by water applied with the engine, brush, or sponge. Mean, early in March, when he top-dresses his plants, applies a copious washing with the engine, or brush; then rubs the shoots up and down the tree, with a brush or sponge, as high as 76°, which effects the destruction of the red spider; while the stems and leaves are wiped with a wet sponge to remove other insects and dirt. (Hort. Trans. ii. 284.) Henderson destroys the aphid by fumigation; the red spider by sprinkling and dashing with water; the coccus, by laying on the leaves with a brush some five times with solution in water, or by withering and dusting the leaves with sulphur; and the only remaining insect which infects the orange, the thrips, he destroys with water. (Cited. Hort. Mem. 315.)
5952. The pomegranate is a low deciduous tree, rising fifteen or twenty feet high, thickly cloathed with twiggy branches, some of which are armed with sharp thorns. The leaves are long and narrow, of a light shining green with red veins. The flowers are produced at the ends of the branches, in the shoots of the same year, single or three or four together; frequently one of the largest terminates the branch, and immediately under that are two or three smaller buds, which continue a succession of flowers for some months, generally from June to September. The calyx is very thick and fleshy, and of a fine red color; the petals are scarlet. The fruit is a berry covered with a hard coriaceous rind, and beautifully crowned with the tube of the calyx, which is sharply toothed, and remains even after the fruit is ripe, contributing greatly to its singular and beautiful appearance. The fruit ripens in October, and, in a green-house, will hang on the trees till the spring or summer following. It is a native of most parts of the south of Europe and of China. In Languedoc, and some parts of Italy, it is used as a hedge plant. It was cultivated in England in 1596, by Gerard; but though it grows very well in the open air, it seldom ripens its fruit so as to render them worth any thing. It used formerly to be kept in boxes, and housed like the orange-tree, which is still the practice near Paris and in the Netherlands. Some of the orange and pomegranate trees in the orangery at Versailles, Risco informs us, are believed to be between two and three hundred years old.

5953. Use. The fruit having an acid pulp is very refreshing, and is eaten like the orange; its singular and beautiful appearance contributes to the variety of the dessert. It is used medicinally in fevers and inflammatory disorders; being powerfully acid and astringent.

5954. Varieties. The Paris nurseries propagate the following sorts: those marked thus (*) may be had in the London nurseries.

The wild, or very acid-fruited The semi-double, and double red and The proliferous; in which a shoot white-flowered * fruit proceeds from the middle of the The subacid-fruited, or cultivated double red and white The yellow-flowered * The variegated-flowered

5955. Propagation. The single-flowering sorts may be raised from seed, and all the varieties by cuttings, suckers, or layers, or by inoculation or grafting on the wild sort. The last is considered much the best mode where fruit is the object; and the next best is by layers, but the common mode is by suckers, which these plants send up abundantly. Inoculated plants, both of the single and double sorts, may be procured from Genoa; and this is the most desirable plan where the plant is to be cultivated for its fruit.

5956. Culture. The directions given for raising and cultivating the orange-tree may be considered as equally applicable to the pomegranate, which, with the olive, was formerly the common companion of these trees in conservatories. Miller has observed, "that both the single and double pomegranate are hardy enough to resist our most severe winters in the open air; and that if planted against walls, the former will often produce fruit, which ripens tolerably well in warm seasons, but ripening late, are seldom well tasted." Where it is to be grown for fruit, therefore, either the standard or flat trained mode, under glass, as recommended for oranges, should be adopted. A few trees may be introduced along with those of the citrus tribe. The soil. Miller recommends a strong rich soil, in which he says, "they flower much better, and produce more fruit than if planted on dry poor ground." In regard both to soil and mode of growth, the pomegranate bears a close resemblance to the hawthorn.

5957. Pruning and training. As already mentioned, the flowers of this tree always proceed from the extremities of the young shoots, produced every year, by which, as the weak branches of the former year should be cut out, and the stronger shortened, in order to obtain new shoots in every part of the tree. When the trees are trained against a wall, the shoots having small leaves, may be laid in four or five inches asunder. The season for the winter pruning, Miller says, is about Michaelmas; for if left till spring before they are pruned, they seldom put out their shoots so early. In summer they require no other dressing than pinch- ing off fore-right and over vigorous shoots, as it is the middling only which are fruitful. In a warm situation Miller obtained a great quantity of fruit from trained trees; which, though not very well flavored, were of full magnitude, and made a very handsome appearance on the trees. The double and other varieties, cultivated for the sake of their flowers, should be pruned, whether in boxes or against walls, on the same principle.

5958. The olive is a low branchy evergreen tree, rising from twenty to thirty feet, with stiff, narrow, bluish-green leaves. The flowers are produced in small axillary bunches from wood of the former year, and appear in June, July, and August. The fruit is a berried drupe of an oblong spheroidal form, darkish thick flesh, always a yellowish-green color, but turning black when ripe. The tree is supposed to be originally from Greece; but it is now naturalised in the south of France, Italy, and Spain, where it has been extensively cultivated for an unknown length of time, for the oil expressed from its fruit. The tree attains an incredible age. Near Terni, in the vale of the cascade of Marmora, is a plantation above two miles in extent, of very old trees, and supposed to be the same plants mentioned by Pliny, as growing there in the first century. It appears to have been cultivated in the botanic garden of Oxford, in 1648, and is generally treated as a green-house plant. With protection from severe frost, Miller says, "it may be main-
tained against a wall in the latitude of London." In Devonshire, some trees have stood the open air for many years; but the fruit does not arrive at maturity. Some trees planted against a warm wall at Camden House, near Kensington, succeeded so as in 1719 to produce fruit fit for pickling.

5959. Use. At the dessert, and frequently, also, during dinner, unripe olives appear as a pickle; which, though to those who taste it for the first time, it appears somewhat harsh, yet it soon becomes extremely grateful; and is said to promote digestion and create an appetite. Pickled olives are prepared by steeping in an alkaline lessive, to extract a part of their bitter; they are next washed in pure water, and afterwards preserved in salt and water, to which an aromatic, as fennel, &c. is sometimes added. The ripe olive, pressed and washed with hot water, furnishes, when skimmed, the well known condismit and corrective, salad-oil, employed both in food and medicine. It may be considered as the butter of Italy and Spain.

5960. Varieties. In the olive-countries these are nearly as numerous as the sorts of the grape and fig. The French (N. Cours, &c. in loco) describe between thirty and forty sorts. The following are grown in English nurseries:

| The common | Large-leaved | Broad-leaved | Iron-colored | Twisted-leaved | Box-leaved.

5961. Propagation. By seeds, cuttings, layers, suckers, and inoculation. The last mode is adopted where the culture of the olive is conducted with care; but the olives, or olive-plantations, are generally furnished from suckers, which arise abundantly from the roots of old trees. In England, as a green-house plant, it is raised from cuttings; but where it is intended to grow a few trees in the forcing-department, for the sake of their fruit, we would recommend procuring strong plants from Genoa; these will produce fruit in three or four years, but the others not for an unknown period of time.

5962. Culture. Some plants used formerly to be received by the Italian merchants along with their imports of orange-trees, and were planted, like them, in pots or boxes; but in order to grow the tree for fruit, the modes to be adopted are either planting as standards in the area, or training on a wall, as recommended for the orange and pomegranate. If a house can be appropriated for it and the pomegranate, giving each their respective soils, and recollecting that the olive will not bear a very high degree of heat.

5963. Soil. The olive will grow luxuriantly in a strong clayey richly manured soil, but will not prove nearly so productive in clay, sand, sandy, or rocky situation; which ought to be imitated in some degree in the composition prepared for the area or border of the olive-house.

5964. Temperature. That suitable for the orange will agree with the olive; but it cannot bear so high a degree of heat as that plant, never being found in Africa south of Atlas, nor in the East or West Indies. It is also easily affected by cold, but not more so than the orange.

5965. Pruning. The object here is to have a regular distribution of wood of the former year, from the axils of the leaves of which, the flowers spring out. When shoots of three or more years are shortened for this purpose, they do not produce good fruit of the preceding or current year may be shortened, and the shoots proceeding from them will produce blossoms in due course. Ringing, to induce fruitfulness, was practised on the olive so early as the seventeenth century. (Boe, in N. Cours, &c. art. Olivier.)

SUBSECT. 4. Indian Fig, or Prickly Pear. — Cactus opuntia, L. (Knob. Theos. l. t. E. a.) Icos. Monog. L. and Cacti, J. Roquette, Fr.

5966. The genus cactus consists of succulent plants, permanent in duration, singular and various in structure, generally without leaves, and having the stem or branches jointed, and for the most part armed with spines and bristles. The joints or branches of the C. opuntia are ovate, compressed, and have very small cadaverous leaves coming out in knots on their surface, and accompanied by four short bristly spines. The branches spread near to, or trail on the ground. The flowers come out on the upper edges of the branches in June and July. The fruit is in the form of a fig or pear, with clusters of small spines on the skin, which encloses a fleshy pulp of a red or purple color, and agreeable succad flavor. It is a native of Virginia and Barbary, but is now naturalised in the south of Italy, being found on the rocks at Terracina and Gaeta. It was cultivated in England by Gerrard, in 1596, in the open air, but without bearing fruit. It was cultivated in the stowe by Justice at Crichton near Edinburgh, in 1750, and ripened its fruit. Miller says, "it will live abroad in England in a warm situation and dry soil; but in severe winters will be destroyed if not protected from frost."

5967. Use. The fruit is sent to the dessert in the West Indies; and might add to the variety of exotic fruits in this country. Braddock observes (Hort. Trans. ii. 293.), that in countries where the fruit abounds, it is considered very wholesome, and though the taste of it is not agreeable to all persons till after they have eaten of it several times, yet they soon become very fond of it.

5995. Sours. There are several species of that division of the genus cactus, called prickly pears or figs, which produce edible fruit, cucumbeorous, succulent, and in the countries in which the Indian fig, or upright prickly pear, (C. funa) (Plunt. grasse 1583;) oblong Indian fig (C. ficus Indica) (Reich, vol. ii. 470;) Barbadoes gooseberry (C. peregrina) (Dill. ett. t. 257. f. 594:) the C. opuntia is deemed the most hardy, and by consequence the easiest to fruit in Britain; but there can be no doubt that the other sorts might also be brought to produce their fruit with very little expense or trouble. They are at present kept in dry-stoves for the sake of variety.

5996. Propagation and culture. All the above sorts may be propagated from seed or cuttings; the latter mode is most common. Cut off the branches at the joint, in July, or after the first shoot has done flowering, and let them dry for a fortnight, that the wounded part may be healed over; then plant in small pots, and plunge in the bark-bed, or in a moderate hot-bed, watering sparingly, giving air to avoid damps, and shading from the midday sun.

5997. Soil. Miller recommends the following: one third of light fresh earth from a pasture; a third
part of sea-sand; and the other part, one half rotten tan, and half lime rubbish. These are to be mixed and laid in a heap, three or four months before using, turning it over once a month; then pass it through a rough screen, but do not sift it fine; reserving some of the small stones and rubbish to lay at the bottom of the pots, in order to keep an open passage for the moisture to drain off. The Barbadoes gooseberry requires less lime-rubbish and more of vegetable earth.

5963. Culture. All the sorts, excepting the prickly pear, require the temperature of a dry-stove in winter, and an increased degree of heat, say 50° or 60° in summer, when it is intended they should produce fruit. They may either be planted in large boxes, filled with the soil above described, with a portion of vegetable mould added; or in borders, to be trained on a wall or trellis near the light. In either case, by supplying them liberally in summer, whilst in a growing state, with heat at bottom and top, air, light, and some moisture, they will thrive abundantly, and produce fruit certainly not of exquisite flavor, but agreeable and singular, and worthy of being added to the British dessert.

5972. Culture of the prickly pear in the open air. Braddock having eaten, with pleasure, of this fruit in Virginia, it was desirous of cultivating it here. He recollected that the plant in its wild state delighted in a dry soil, amongst rocks, near the skirts of the sunny sides of the forest; and having heard that it would stand the open air in this country, he planted it in the spot described below, planted in a sheltered place, but that it turned out has lived in the open ground of this country for six or seven years, during which period it has endured one exceeding hard winter, and several trying springs; and in all, except the two first years, it has never failed to ripen its fruit and seeds, so that it may now considered decidedly acclimated. The compost used by me for growing this plant, which must be placed in the middle of a small artificial hillock, raised eighteen inches above the surface of the ground, which ground should be rendered perfectly dry, if not so naturally so, by under-draining. Neither the leaves, flowers, nor fruit should ever be suffered to touch the ground, but they should, as constantly as they are produced, be kept from the earth by placing stones, pebbles, flints, or bricks under them, in imitation of artificial rock-work.” (Hort. Trans. 228.)

5973. The torch-thistle, or upright cereus, of which there are four species which bear edible fruit, and the strawberry-pear (C. triangularis), the poire de chardon of the French, may also be cultivated as fruit-bearing stove plants, in the same way as recommended for the Indian fig.

5974. The introduction and cultivation of new exotie fruits may be considered as a very rational and entertaining object, for such as have the means, the time, and a taste for gardening. It seems to deserve the particular attention of retired persons of solitary habits, aged or inactive, by presenting an end to be attained; it may serve as a gentle stimulus to such as, from indolence or bilious complaints, are apt to sink into a state of torpid unenjoyed existence. A few of the plants, which we shall here enumerate, have been cultivated so as to produce fruit in this country, as the granadilla, lee-chec, loquat, banana, &c.; most of the others have hitherto served only to increase the variety of our stove or green-house plants.

5975. The akee-tree is the Blighia Sapida, H. K. (Ann. Bot. 2. t. 16, 17.) Oct. Monog. L and Sapindl. J. (fig. 528.) It is a tree rising from twenty to twenty-five feet in height, with numerous branchless, and aristate pinnate leaves, like those of the common ash. The flowers are small, white, on axillary racemes. The fruit is a pome, reddish or yellow; about the size of a goose's egg, with a pulp of a grateful subacid flavor, and in the West Indies esteemed very wholesome and nourishing. It is a native of Guinea, and was introduced in Jamaica in 1779, and from thence brought to this country in 1783.

5976. Propagation and culture. It may be propagated from seeds, cuttings, or layers; but as the former mode would prolong the period of culture for fruit, and the two latter produce but weak plants, the better plan would be to order a few trees to be inoculated in Jamaica, and then sent over in tubs; these might be treated as directed for orange-trees (5920), and then planted in a border of rich earth, and submitted to a Jamaica climate, and flat-trained near the glass. By such treatment, there can be no doubt the akee-tree would in a few years produce fruit as readily as the orange.

5977. The alligator, or avocado pear, is the Laurus Persea, L. (Plak. Amer. t. 251. f. 1.) Einn. Monog. L and Lauri. B. P. It is a tree growing in the West Indies, grows to the height of thirty feet or upwards, with a trunk as large as that of our common apple-tree. The leaves are like those of laurel, of a deep-green. The flowers are pollinated towards the extremities of the branches. The fruit is the size of one of our breakfast apples, but large in gross肉体, and a perfect firm consistence, and has a delicate rich flavor; it gains upon the palate of most persons, and becomes so agreeable even to those who cannot like it at first; but it is so rich and mild, that most people make use of some spices to give it taste; and for this purpose some make use of wine, some of lime-juice, but most of pepper and salt. Miller, from whom the above account is extracted, cultivated it in 1739.

5978. Propagation and culture. Miller gives directions for raising the tree from seeds, which, he says, may be brought over in dry sand from the countries where it is cultivated. There is nothing uncommon in the process of raising, which is conducted in a hot-bed or pit; and when the plants have made their summer shoots, they are removed to the stove during winter. But where it is intended to cultivate this tree for its fruit, a better way would be to send to the Botanic Garden of St. Vincent's, and request
The practice but the fruit and might be introduced, horizontal training and ringing, accompanied by a Jamaica temperature, would soon produce fruit.

5979. The anona-pear is the Grias cautiflora, L. (Stoan. Hist. 2. t. 217. f. 1.) Polyg. Monog. L. and Cottufa, J. (fig. 524.) It is a stow tree, frequently growing to the height of fifty feet in the West Indies, where it is a native. The leaves are oblong, and two or three feet long. The flowers numerous on short peduncles, large and whitish. The drupe is ovate, and crowned with a calyx like the pomegranate, about the size and shape of an alficostructor's egg: it is picked, and eaten like the East Indian mango, which it greatly resembles in taste. It grows generally in low moist bottoms, or shallow waters, and has a most elegant appearance. Introduced here from Jamaica in 1768.

5980. Propagation and culture. It is very readily propagated from the stones, and the plants must be kept in a moist heat. To grow it for fruit, plant in a border, and train horizontally near the light, as directed for the avocado-pear. (5978.)

5981. The durian is the Durio Zibethina, L. (Rumph. Amb. p. 99) Polydolp. Polyg. L. and Capparides, J. (fig. 525.) This is a lofty East Indian tree, with leaves resembling those of the cherry, and large bunches of flowers coming out below the leaves, of a pale-yellow color. The fruit is the size of a man's head, roundish or oblong; resembling in some degree a rolled-up hedgehog, with a hard bark or rind; the fleshy part of the fruit is of a creamy substance, and of a delicate taste; but of an unpleasant heavy smell, somewhat resembling that of rotten onions; and the smell of the breath of those who eat it is infected also in a high degree; but when once a person has accustomed himself to eat this fruit, he generally considers it the most excellent of all. Rumphius says, it is by much the most excellent fruit of India. The tree has not yet been introduced; but if a few fruit or plants were sent for from the Calcutta garden, and submitted to the general plan of culture for trees difficult to procure, there can be no doubt of success.

5982. The red guava is the Psidium guajava, L. (Rumph. Amb. 1. t. 47.) Icos. Monog. L. and Myrti, J. (fig. 526.) It is a West Indian tree, growing to the height of seven, eight, or twelve feet, with numerous branches and blunt, entire, smooth leaves, two or three inches long; the flowers are in solitary peduncles and sweet-smelling; fruit bigger than a hen's egg, roundish or oblong, smooth, yellow; the rind thin, brittle, and yellow; pulp firm, full of bony seeds, flesh-colored, sweet, aromatic, and pleasant. It is eaten with avidity both by West Indians and Europeans, raw in the dessert, and preserved with sugar. It has been grown here as a stow plant since 1668; it is propagated by seeds from ripe fruits brought over; and to be fruit should be treated as directed for other similar fruit-trees already mentioned.

5983. The red guava (P. pomiferum) has a beautiful fruit, crowned like a pomegranate; but is not so agreeable to eat as the other.

5984. Cattley's guava, P. Cattleyanum. A new species introduced from China by Messrs. Barr and Brooks, nurserymen, and fruited by W. Cattley, F. H. S., in 1820. The plant resembles the other species in general habit and appearance; but the fruit is larger, nearly spherical, of a fine dark claret color, growing in the axilla of the leaves; the skin has much the consistence of that of a ripe fig, but is thinner; the interior is a soft fleshy pulp, purplish-red next the skin, but becoming paler towards the middle, and at the centre it is quite white; it is juicy, and in consistence is much like a strawberry, to which it bears some resemblance in flavor. (Hort. Trans. iv. pl. xi. 317.)

5985. The jamun, or rose-apple, is the Eugenia jamnua, L. (Parr.舆. 38.) Icos. Monog. L. and Myrti, J. (fig. 527.) It is a branchy tree, rising from twenty to thirty feet high, with long narrow leaves not unlike those of the peach. The flowers come out in terminal bunches in July, are of a greenish-yellow color, and succeeded by fruit about the size of a hen's egg, white, red, or rose-scented, with the flavor of a ripe apricot, and ripening from September to December. It is a native of the East Indies, and was cultivated here by Miller, in 1768. There are several varieties of this tree differing in the size and color of the fruit. That with white fruit has been cultivated by Professor Thouin in the National Garden at Paris. This horticulturist endeavored to harden the tree by exposing it annually to the open air during the two hottest months of the year; but, after persisting in this mode of cultivation for several years, and finding the leaves and part of the fruit dies off annually, in consequence of the cold while exposed, he at last had recourse to a hot and moist atmosphere, and was successful. (Hort. Trans. i. App.) Cattley has a plant which regularly yields him abundance of fruit. (Hort. Trans. v. 112.)

5986. The Malay apple is another species of Eugenia (E. Malacens). (Bot. Rep. 485.) The tree resembles the former, but has broader leaves. The fruit is ovate, an inch and a half in diameter, fleshy, very sweet-smelling, like the rose, agreeable to the taste, smell, and sight, and esteemed wholesome. It is common in most of the islands in the South Sea, and was cultivated by Miller in 1768.

5987. The bastard guava (E. Pseudo-Psidium) and the Cayenne cherry (E. cotinifolia) produce
edible fruits, held in considerable esteem in the West Indies, and with the Malay apple appear to deserve culture in this country. (See Miller’s Dict.)

5888. The custard-apple (Anona reticulata), alligator-apple (A. palustris), sweettop (A. squamosa), and sourtop (A. muricata), are esteemed West Indian fruits; and the Cherimoya (A. tripetala), the Cherimola of some botanists, is the fruit most prized by the natives of Brazil and Peru. All these plants are already in our stoves, and might easily be cultivated as fruit-trees.

5889. The mamee-tree (Mammea americana, L.) Polyana. Monog. L. and Guttifera, J. is a tall handsome tree, with oval, shining, leathery leaves, and one-flowered peduncles, producing sweet white flowers an inch and a half in diameter, succeeded by roundish fruit, about the size of an egg, and in pulp and taste not unlike the apricot. It is eaten raw alone, or cut in slices with wine and sugar, or preserved in sugar. It is a native of the Caribbee Islands, and was cultivated in 1738 by Miller.

5900. Propagation and culture. It may be raised from the stones or seeds, and treated like other stowe fruit-trees. It has been naturalised by Knight, who found it rather impatient of a very high temperature. (Hort. Trans. iii. 454.)

5901. The leechee and long-yan. The leechee is the Dimocarpus Litchi, W. (Lam. iii. t. 393.) Octaen. Monog. L. and Sapindi, J. It is a stowe tree, with compound leaves, not unlike those of the common ash-tree; a native of China, and introduced in 1786. The fruit is a berry of a red color when ripe, except in one variety, which remains green: it is much esteemed by Europeans.

5902. The long-yan or the B. Longan, H. K. B. (Buck. t. 792.) The tree resembles the former, but the fruit is not so large, and is of a light brown color. “In both species the pulp of the fruit is surrounded with a tough, thin, leathery coat; it is a colorless, semi-transparent substance; in the centre of which is a dark-brown seed of different sizes in the different varieties. The flavor of the pulp is slightly sweet, sub-acid, and particularly pleasant to the taste in a warm climate. The fruit of the leechees, dried either in the sun or by fire-heat, is frequently brought from England from China. In this state the pulp is shrivelled and reduced within the coat, or shell, to half its usual size, and has a rich and sweet taste, if it has been well preserved. The fruit of the long-yan is sometimes ripened by John Knight, Esq. of Lee Castle, in a lofty stove, erected for the purpose of growing tropical fruits; and a bunch was presented by him to the Hort. Society, in September, 1816, supposed to be the only one ever produced in Europe, and which persons well acquainted with the long-yan in its native places of growth, pronounced quite as good as those grown within or near the tropics.” (Hort. Trans. ii. 48.)

5903. Propagation and culture. Both species may be raised from seeds or layers, and the plants may be afterwards placed in a bed or area of rich soil, and trained or spread out near the glass. The temperature should never be under that of the pine-apple.

5904. The loquat is the Mespilia Japonica, L. (Fent. Mal. iii. 19. and Hort. Trans. iii. tab. 11.) Erubodryna japonica, Lam. Icos. Di-Pent. L. and Rosaceae, J. (fig. 528.) In a wild state it is a lofty tree with thick knobbed branches, and tomontose spray or branches; the leaves are narrow, a span long, bright-green and cinereous tomontose below. The flowers come in spikes at the ends of the shoots in October and November. The fruit is a five-celled pome, about the size of a gooseberry, and in taste approaching to that of the apple. It ripens in May and June. It is a native of Japan, and was introduced in 1787 to Kew-gardens, where, as well as in some other places, it has produced fruit.

5905. Propagation and culture. It may be raised from seeds, or continued by cuttings or layers; but the best method, when it is intended to produce fruit, is to graft it on any other species of mespilus. It is considered as a frame or half-hardy tree; but, to ripen its fruit with flavor, should have the temperature of the stove, in which, planted in a border of rich soil, it will add to the variety of the dessert. Sir Joseph Banks (Hort. Trans. i.) considers the fruit as equally good with that of the mango. Lord Bagot, who has fruited the plant in a very superior manner for several years at Blithfield, gives the following outline of his practice: “The plan I have usually followed has been to give it a

winter (out of doors) during the months of July, August, and September, and about the middle of October to remove it to a warm situation in the room. This summer, however, I was obliged to alter my mode; for, just at the moment when I was going to put it out for its winter, it became covered with at least twenty bunches of the finest flowers possible; I was therefore obliged to let it remain where it was. The present year’s treatment, therefore, is an exception to the former practice; under that, it usually breaks into flower about the end of December, and the fruit becomes ripe in March or April. The last time my plant was in fruit, Sir William Coke, who had resided many years in Ceylon, where he is at present, was with me at Blithfield; he told me that he was in the constant habit of eating very large quantities of the fruit daily in that island, but that he had never tasted any so good, and with so much flavor, as those I have produced in my garden.”

5906. The mango-tree (Mangifera indica, L. (Bot. Rep. 425.) Pent. Monog. L. and Tercibates, J. (fig. 529.) is a large spreading tree, like the walnut, with lanceolate shining green leaves, seven or eight inches long, having a sweet resinous smell; the flowers are white, growing in bunches at the extremity of the branches. The fruit a drupe, large, kidney-shaped, covered with a smooth, soft-skin, resinous pale-green, yellow, or half-red skin, and containing an ovate, woody, fibrous, compressed nut or stone,
within which is an ovate kernel, soft and pulpy, like a damascene plum. "When ripe, it is replete with a fine agreeable juice; it eats like an apple, but is more juicy, and some are as big as a man's fist. It is esteemed a very wholesome fruit, and, excepting very fine pine-apples, is preferable to any fruit eaten in Europe; generally brought to market in the hot months of July and August. "In Europe we have only the unripe fruit brought over in pickles." (Martyn, in Miller's Dict.) It is a native of the East Indies, and was introduced in 1600; but has not yet been cultivated for its fruit. According to Governor Raffles, forty varieties of mango are known in Java.

5911. Propagation and culture. It may be increased by cuttings like the gardenia, which it somewhat resembles in habit, or from nuts; but as the vegetative quality of these does not seem to admit of long preservation, they must be enveloped in wax, or otherwise managed, to preserve it. Many will not yield from the potted plants, and it recommends the dry stove, a temperate heat, and light kitchen-garden earth. This tree seems particularly deserving culture for its fruit, both on account of its quality, and the plants not requiring so much heat as most of the other unriiled Indian fruits. Knight raised some mango-plants from seeds in October, 1815, which in the following March had blossoms; he is "much inclined to believe that the mango might be raised in great abundance, and considerable perfection, in the stove, in this country; for it is a fruit which acquires maturity within a short period. It blossoms in Bengal in January, and ripens in the end of May." (Hort. Trans. vol. iii. 405.)

5912. The pishimah, or European date-plum, (Diospyros Lotus, L. (Mill. t. 116.) Polyg. Dicot. L. and Ebenaceae, B. P.) is a small tree, rising six feet high, with spreading branches, and large shining lanceolate leaves. The flowers are small, of a reddish-white; the fruit is a berry half an inch in diameter, yellow when ripe, sweet, and somewhat astringent: it is used like the medlar, in a state of incipient decay, in the West Indies; and Passiflora, L. was introduced to this country in Gerrard's time, and will grow in the open air, but will ripen its fruit freely.

5913. Propagation and culture. It may be raised from seeds sown in a hot-bed, and afterwards hardened, or from layers; but when it is intended to fruit the plant, it may be procured from Genoa, a good many nurseries in France, and it will not fail to mature its fruit.

5912. The granadilla, or little pomegranate. This name is applied to the edible fruit of five species of the Passiflora genus; Monadel. Pentan. L. and Passiflora, J. The common character of which is that of climbing herbaceous plants, woody at bottom, generally with lobed leaves, and all natives of warm climates.

5913. The granadilla, or granadilla-vine of the French, is the P. quadrangularis, L. (Bot. Reg. 14.) The leaves are oval and subcordate, five or six inches long and entire; the stem luxuriant and four-cornered. The flowers are odoriferous, red within and white on the outside, and appear in August and September. Both fruit and flowers growing at the same time. The fruit, Sabine describes (Hort. Trans. iii. 100.) as very large, of an oblong shape, about six inches in diameter, from the stalk to the eye, and fifteen inches in circumference. It is externally of a greenish-yellow when ripe, soft and leathery to the touch, and the rind is very thick and contains a succulent pulp of a purple color (which is the edible part), mixed with the seeds, in a sort of sack, from which it is readily separated. Wine and sugar are commonly added to it, when used. The flavor is sweet, and slightly acid, and it is very grateful to the taste, and cooling in a hot climate. It is a native of Jamaica, and other West India islands, where it grows in the wild state. It was cultivated by Miller in 1768, and now cultivated by gardeners. It has been successfully cultivated for its fruit in a few places, as at Lord Harewood's (Hort. Trans. iv. 60), Farney Hall, &c.

5914. The apple-fruited granadilla, or sweet calabash, is the P. multiflora, L. (Bot. Reg. 60.) It has a calyx with lobes, six inches long, and four broad, in the middle of a viviparous plant. The flowers are sweet-scented, large, of a pale red and blue: "the fruit round, smooth, about two inches in diameter, of a dingy yellow color when ripe; the coat is hard and stringy, nearly a quarter of an inch in thickness, full of a very agreeable gelatinous pale yellow pulp, in which many odoriferous seeds are lodged," (Mill. Trans. ii. 101.) and it is eaten like that of the former species. It is a native of the West India islands, and was introduced here, and cultivated by Miller in 1713. It has borne fruit in the stove of the Bishop of Durham in Oxfordshire, and at Vere's, Kensington Gore. 5915. The granadilla, or Pome de Liane of the French, is the P. tauriflora, L. (Bot. Reg. 12.) It has a suffrutescent stem, with divaricating filiform branches, oval smooth leaves, and very long tendrils. Flowers red and violet, sweet scented; the fruit about the size of a hen's egg, but rather more elongated, and tapering equally at both ends; when ripe, it is yellow and dotted over with white spots; it contains a whitish watery pulp, which, in the West Indies, is usually sucked through a small hole made in the rind; the rind is tough, soft, and thin; the juice has a peculiar
EXOTIC FRUITS LITTLE KNOWN.

Book I.

EXOTIC FRUITS LITTLE KNOWN.

878

aromatic flavor, is delicately acid, and allays thirst agreeably. It is a native of Martinique and Surinam, and was introduced here in 1690. It is grown in the stove, but has not yet been cultivated for its fruit.

6006. The purple-fruited granadilla (Hort. Trans. vol. iii. pl. iii.) (fig. 531), is by some botanists considered as a variety of *incarnata*, but by Sabine, who thus describes it (*Hort. Trans. iii. 99*), as a distinct species. "The stem is thick and woody, the leaves three-lobed, and of considerable size; the flowers proceeding from the axils of the leaves, fragrant, and of a white color, tinged with purple. The fruit when ripe, is green, but as it ripens changes to a dark livid purple, and much resembles the fruit of the purple egg-plant. The shape is globular, an inch and a half in diameter, and two inches from the stalk to the top; the pulp is orange-colored, and the seeds numerous; the taste acid, and the flavor somewhat like that of the orange. It is a native of Brazil, was introduced from Portugal by Boehm, in 1810, and has produced fruit abundantly in the stoves at Walton-on-Thames, at the royal gardens at Windsor, and other places. Such is the rapid growth of this species, that a single plant will in one season extend its branches over a stove, and grow a line over upwards of forty feet of glass, on which space it will produce from 400 to 500 fruit."

6007. *P. granadilla*, or *May apple*, is the *P. incarnata*, l. (Abb. in Geogr. t. 15). The root is perennial, sending up annually a number of herbaceous shoots, with three-lobed leaves, and sweet-scented flowers, variegated with purple, and appears from July to September. The fruit when ripe is about the size of an apple, orange-colored, with a sweetish yellow pulp. It is a native of Virginia, was cultivated in the open air by Parkinson in 1629, and afterwards by Miller in the stove, with whom it bore fruit.

6008. Propagation and culture. All the sorts may be propagated from seed, layers, and even cuttings; but layers come soonest into bearing. Having procured plants with good roots, plant such as are intended to fruit in a border in the stove, and train them to a trellis near the glass; they will in general produce fruit in the second year. The seedlings of the purple-fruited sort will produce fruit the first year. All the species will fruit even in large pots; but Sabine says, the "best method is, to plant them in an angle of the bark-bed, which has been parted off, either by boards or nine-inch brick-work, as low as the pit goes. At the bottom of the cavity, formed by this division, should be laid some brick-rubber, over which may be placed a clean layer of sand, and then filled with equal parts of very old tan, and a compost of leaf-mould and rotten dung. Herein the roots will strike freely, and will even spread through the partition into the pit, growing into the fresh tan. Such roots may be trimmed and reduced whenever the tan is changed; but should the plant have been some time in its station, it will be as well to leave part of the soil in the bottom of the pit, in which the protruded roots may remain undisturbed. They do not require the full heat of the pine-stove, for they flourish best in a temperature of from 65 to 70 degrees; but they do not bring their fruit to perfection if kept in a common green-house or conservatory, though they will remain in it. They are a plant which must be trained near to, and under the inclined glass of the stove: the first flowers will appear in May, and the blooming will continue until September, the fruit setting the whole time; but if it does not set well, it will be advisable to impregnate the stigmas, by applying the pollen with a feather. As they grow, the very strong shoots should be cut out freely, or these do not produce fruit. Those which are less abundant, but which flower branches must not be shortened on any account. The temperature must be kept up equally, during the time of blooming and fruiting; the crop will begin to come in August, and will continue until January; but the earlier produce is the best. When the crop is all off, which will be early in January, the shoots must be reduced to about 50%, so as to check or stop the growth; this being effected, the shoots must be well cut in. As little old wood as possible, besides the main stem, which rises from the pit to the glass, and a few pieces (about two or three feet of each) of the old branches should be retained: for all the shoots which come through the glass must be removed. In early March, the shoots having been reduced to about 50%, it is found that the shoots break better, and in greater quantity, from the older wood than from that of two years' standing. In this dormant and reduced state it is to be kept during January and February, after which the necessary heat may be applied to cause it to resume its functions for the ensuing season."

6009. The coco-nut-tree, is the *Cocos nucifera*. L. (Roxb. Cor. I. t. 73.) *Monoc. Hecan. L. and Palmae, B. P.* (fig. 532). It is an East Indian palm; but cultivated in most places within the tropics. The tree grows to a great height, with leaves thirteen or fourteen feet long; the flowers come out round the top of the trunk of the tree in large clusters, enclosed in a spatha or sheath; and the nuts succeed them commonly ten or twelve together. Their form and use is familiar.

6010. Propagation and culture. The nuts are to be planted where they are designed to remain, as the tree will not bear transplanting unless when very young. In a moist heat they will push in six weeks or two months. To cultivate for fruit, plant in the centre of the area of a house, twenty-five feet wide, and either lofty, or with a moveable roof, which will admit of being raised as the tree advances in height. In this way, with a strong heat, there can be no doubt this tree would produce fruit in England; but even if it did not, or did not for a great many years, the magnificence of its appearance, under such a mode of treatment, would compensate a curious horticulturist for the labor and expense paid for it. Though the coco-nuts are to be obtained in the shops are supposed to be gathered before being ripe, yet they have been found to grow with no other care than planting in a large pot or box of rich earth, and plunging in water for a few hours. This is a most the only palm that could be cultivated in this country for perfecting its fruit; for the others being dioecious plants, unless a great number were grown together, there would be no legitimate means of impregnating the female blossoms.

6011. The plantain-tree (Musa paradisiaca, L. *Her. Monog. L. and Musaceae, P. S.*) rises with a soft, herbaceous, conical stalk, fifteen or twenty feet high, with leaves issuing from the top, often more than six feet long, and near two feet broad; the spike of male and female flowers appear from the centre of the leaves, and is succeeded by pudding-shaped fruits, eight or nine inches long, above an inch in diameter, pale-yellow when ripe, of a soft, sweet, luscious flavor; the spikes often so large as to weigh upwards of forty pounds. It is a native of the East Indies, and other parts of Asia, and probably of Africa,
and was cultivated at Hampton Court in 1600. Gerard says, the pulp eats something like that of a muskmelon; he calls the plant Adam's apple-tree, from a notion that it was the forbidden fruit of Eden; others suppose it to have been the grape brought out of the promised land to Moses. Dampier says, it is the king of all fruit, not excepting the cocoa itself. There are numerous varieties.

6019. The banana-tree (M. sapientum, L. [fig. 533]) differs from the plantain in having its stalks marked with dark-purple stripes and spots, and the fruit is shorter and rounder. Some botanists, however, consider them as only one species. The stalk is hollower than the other, is eaten raw or roasted, in fritters, preserves, marmalades, and the fermented juice affords an excellent wine. It has been cultivated for upwards of seven years, at Wynnstay, the seat of Sir W. W., Wynne, in Denbighshire. Specimens were sent to the Horticultural Society in August 1819, which were between four and five inches long, and possessed an agreeable, juicy, and acid flavour. The fruit, produced from a single plant, is so abundant, as to entitle the banana to be considered as a useful fruit for the table.

6012. Propagation and culture. Suckers rise from the roots, and should be planted in light rich earth, in pots, and afterwards, if the plant is cultivated for its fruit, planted in a bed or pit of earth, kept rather moist. The plant at Wynnstay was planted in the bed of a stone about 1811. It was then about six feet high, with a single stem. In each succeeding year it has produced a bunch of fruit; but in the present year (1819) two bunches; the first was ripe in May, the other in August, having about dozen fruit each on bunch. The plant is now sixteen feet high, and measures three feet round at the bottom.” (Hort. Trans. iv. 138.).

6014. The bread-fruit. — Artocarpus incisa, L. (Rumph. Amb. 3. t. 83) Monoc. Monan. L. and Urtice. 3. Rima or Fruit-a-pain, Fr. and Broad-burn, Ger. (fig. 534). It is a stave tree, growing in the South Sea Islands, to the height of a moderate-sized oak, with alternate leaves, deeply gashed, glaucous, and two feet long. Aments on the outermost branches, violet-colored, pelted, male and female on the same twig. The whole tree and the fruit, before it is ripe, abounds in a very tenacious milky juice. The fruit is about the size and shape of a child's head, and the surface is rough, not much unlike a truffle; it is covered with a thin skin, and has a core about as big as the handle of a small knife; the edible part lies between the skin and the core; it is as white as snow, and somewhat of the consistence of new bread. It must be roasted before it is eaten, being first divided into three or four parts; its taste is insipid, with a slight sweetness, somewhat resembling that of the crumb of wheaten bread mixed with Jerusalem artichoke. Five plants were brought to England, the remainder of the stock brought from Otaheite by the unfortunate Lieutenant Captain Bligh in 1783. In Professor Martyn's edition of Miller's Dictionary will be found a variety of interesting details relative to this tree, and another species, the A. integrifolium, or Jacca-tree, which also merits culture for its fruit.

6015. Propagation and culture. This tree will grow either from seeds, layers, or suckers; the latter the plants send up abundantly in their native climate. They succeed best in a rich soil; and to induce them to produce fruit, should be treated as already advised for other stave fruits not easily fruited. As the bread-fruit-tree has been introduced in the West Indies Islands, the shortest way would be to procure good sized plants from Jamaica or St. Vincent's though they may be occasionally obtained from the London nurserymen.

6016. The true lotus (Ziziphus lotus, W.), the jujube-tree (Z. Jujuba, W.), and the kaki (Dioglosos Kaki, W.), are branching shrubs or small trees of the easiest culture in Italy, Barbary, and China, and abundant bearers. They might readily be cultivated in this country, as the jujube grows in hedge-rows about Genoa and Nice, it is probably it would bear fruit abundantly in a green-house. The jujube is served up in Italy as a sweetmeat. The fruit of the kaki are orange or apple shaped.

6017. Other exotic fruits. The following have been enumerated by Lindley (Hort. Trans. v. 88.), as mere introduction, or where already introduced, to be cultivated as dessert-fruits.

6018. Of African fruits we might have from Sierra Leone, the cream-fruit, country cherries, country plums and figs; from Congo, the conte, mabocche, gangi, saft, and anona senegalensis; from Loango, the cauza as large as a melon; from Madagascar, the veanato, vouatca, vouacrene, azoualala, and alameto.

6019. From the West Indies, the sappodilla-plum (Acharas Sapodea), country cherries which are various species of Malpighia, the callimatio-tree (Chrysothalamus tereces), the star-apple (Chrysophyllum Cestido), the country plums (Spoudia) various species, the sea-side grape (Cocculus aureus, the garlic-pear (Casta Tepel), and various species of cactus. Most of these fruits are cultivated both in the West India Islands and on the American continent, and plants of all of them may be obtained from the London nurseries.

6020. From South America numerous cultivated fruits may be introduced: from Guiana, the tapiapo (Carica maxima), the caboclo, the pinamo (Annona pinnatiloba), the marmelado-ox of Steedman (Swanam, vol. ii. p. 330); from Brazil, Peru, &c. the achoo (Leonia guayucaroba), the queule or keule (Gouwortea altaida), and others of less note.

We will, from the first fruits in the world that have been obtained, and others are yet to introduce. From the Indian Archipelago, the lane, the lansian (Lansium domesticum), a fruit considered as next to the mango and durian, the rose-water jambu (Eugenia aquea), and other species; the blimming (Averrhoa Carambola), the cheremi (A. acida), the ramiluan (Nephelium lappaceum), the carambola (N. pneuocarpa), the shaeru (Carissa thunbergia), and others. From China and Japan many new sorts of pears and peaches, it is supposed, may be obtained, and probably also apples and other European fruits; the Pomacea and Prunacee occupying the place in higher latitudes which the Myrtaceae, Gutiferae and Terebinthaceae do in countries nearer the equator. From the Society Islands, the Otaheite apple (Spondias cytherea), &c. Though we think it probable that few or none of these, grown in this country, would be
found to equal our best peaches, pears and plums, or even gooseberries and strawberries; yet we cannot but wish to see this or the contrary proved by the wealthy and curious horticulturist.

**Sect. IV. Exotic Esculents, not hitherto cultivated as such.**

6022. Of exotic esculents, some, as the yam and sweet potato, are worthy of being experimented on with a view to their naturalisation as articles of food; and even as furnishing a variety of esculent root, they deserve to be grown and sent to table, where there is a complete or extensive garden establishment.

6023. The West Indian yam (the *iniane* of the Portuguese, and *igname* of the French) is the name applied to several species, with their numerous varieties of the genus Dioscorea, *L. Dienn. Heras*. L. and Dioscorea, var. They are climbing, perennial, herbaceous plants, with tuberous roots, and axillary flowers in spikes or racemes. The name yam is more particularly applied to the *D. setosa*. (Rheed. Mal. *t*. 61.) (fig. 535). This plant has tender stalks, climbing to the height of eighteen or twenty feet, and furnished with smooth-nerved roundish leaves. From the base of the leaves arise spikes of small flowers of no beauty. The root is flat, brownish, a foot broad, and nearly palmed like those of some of the orchids. It is a native of, and cultivated extensively in, Africa and the East and West Indies, and was introduced here from the latter country in 1733. The roots are melon, easy of digestion, palatable, and not inferior to any roots now in use, either for delicacy of flavor or nutriment. They are eaten instead of bread, either roasted on the cinders or boiled; the flower is also made into bread and puddings.

6024. The *D. alata*, (Rheed. Mal. *t*. 38.) or winged yam, is in equal, if not more universal cultivation than the former species. Its roots are frequently three feet long, and weigh thirty pounds. Of both these species there are numerous varieties, differing in the size and form of their roots.

6025. Propagation and culture. They may be propagated like the common potato, and cultivated in nearly the same manner as the forced potatoes. Brown (Hist. of Jam.) affirms, "that the roots must be cut so as to leave a little of the skin to each piece, for by that alone they germinate; the roots having no apparent buds or eyes, but casting out their weakly stems from every part of the surface alike. They are planted commonly in August, and are ripe in November or December following."

6026. The Spanish, or sweet potato, is the *Convolvulus Batatas*, *L. (Rheed. Mal. *t*. 50.) Pent. Monog. L. and Convolvulaceae, B. P. (fig. 536). It is a herbaceous perennial, with a round stem, hispid, prostrate, creeping, of a whitish-green, putting out scattered, elong, acuminate tubers, purple or pale on the outside. The leaves are angular, on long petioles; the flowers purple, on upright peduncles. It is a native of both the Indies, and was introduced here, and cultivated by Gerrard in 1557. He calls the roots potatoes, potatoes, or potatoes, and says, that they are by some named skirters of Peru. They flourished in his garden till winter, when they perished and rotted. Batatas were then sold at the exchange in London, and are still annually imported into England from Spain and Portugal. They were, as already observed (367.), the common potatoes of our old English writers; the *Solanum tuberosum* being then unknown. The tubers of the batatas are sweet, mild, and nourishing. They are very commonly cultivated in all the tropical climates, where they eat not only the roots but the young leaves and tender shoots boiled. There are several varieties, if not distinct species, differing in the size, figure, and taste of the roots.

6027. Propagation and culture. In warm climates this plant is cultivated in the same manner as our potato, but requires much more room, for the trailing stalks extend four or five feet every way, sending out large tubers, forty or fifty to a plant. In the national garden at Paris, the plants are raised in a hot-bed, and about the middle of May, transplanted in the open ground, where they are earthed up, and otherwise treated like the potato. In warm seasons they produce a tolerable crop, and we have been informed by Professor Thouin, that he hopes, after several years, at least so far to acclimate the plant as to fit it for field-culture in the south of France. Lelieur, who grows it in the same manner, also strongly recommends its culture. Both consider it as much lighter food than the common potato, and equally nourishing. In England, Miller observes, the roots must be planted on a hot-bed in the spring, and if the plants are kept covered in bad weather with glasses, they will produce flowers and many small tubers from the joints but if they are exposed to the open air, they seldom make much progress. This, however, ought not to discourage the curious or patriotic horticulturist, either in his attempts to raise the roots for the table, or to acclimate the plant.

6028. The caper (*Capparis spinosa*, *L. Polyan. Monog. L. and Capparidaceae, J.) (fig. 537.) is a trailing shrub, a native of the south of Italy and Sicily, when it abounds on rocks, ruins, and old walls: it has been long cultivated in France, and was introduced in this country in 1596, as a stave plant; but there is reason to believe it may be naturalised. It is cultivated, Neill observes, in the neighborhood of Paris, with no other protection than that of being trained against a low wall, and the shoots in winter laid down and covered with litter or fern, like those of the fig.
In the garden at Camden House, Kensington, a caper-tree stood alive in the open air for near a century; it had a south-east aspect, and was well sheltered from the north; it had no covering, and was generally much injured by the frost; but the roots of this plant being particularly strong and vivacious, it made strong shoots, and produced flower-buds every year. It is probable, therefore, that a plantation, so situated, if covered every autumn with litter, mats, or ferns, would succeed. Such a plantation, not trained on walls, but planted in an open compartment, would, like those near Toulon, in France, have the general appearance of a plantation of brambles, and might be yearly covered with very little trouble. Neill suggests, that a hardy variety might possibly be obtained by repeatedly raising from seed, at first in Guernsey or Jersey, and the plant thus gradually inured to this country. The part used is the flower-bud, which forms a well known pickle, and an article of considerable commerce from Sicily, and other islands in the Mediterranean.

6029. Propagation and culture. It may either be raised from seed, cuttings, or pieces of the root. The authors of the *Oeuvres complets d'Agriculture* prefer the mode by cuttings, and direct them to be cut a foot long, and planted in autumn. The autumn following, they will be fit to remove to a general plantation. They describe two modes of culture; one, that of planting in walls, where no farther care is wanting, but that of gathering the buds; and the other, that of planting in quinconx in open compartments, like other fruit-shrubs; the latter mode is greatly to be preferred.  

6030. The satilla, or edible astraeaemia.—*Astramerea Salisilla*, B. M. (Bot. Mag. 1615.); and *S. edulis*. (Hort. Trans. vol. ii.) *Rez. Monog. L. and Asphodelaceae, B. P.* This is a herbaceous plant of great beauty, a native of Peru, and introduced in 1860. It is cultivated in the West Indies, where its roots are eaten like the potato. It was flowered here in 1811, in the Comte de Vande's garden at Baywater. It requires the temperature of the stove, and may be cultivated in a hot-bed like the early potato.

6031. The bread-root.—*Psoralea corymbosa, Ps. (Paris. Amel. 18. 92.) Dianth. Decne. L. and Leguminose, J.* It is a perennial herb, a native of Missouri, and introduced here in 1811. It will grow in the open air, but requires the protection of a frame to produce abundant crops of roots, which are used like those of the potato in the countries where it is a native.

6032. The pi-tsi, or water-chestnut of the Chinese.—*Scirpus tuberosus*, Rox. (Roz. iii. 56.) *Triand. Monog. L. and Cyperaceae, B. P. (fig. 635.)* It is a tuberous and fleshy-rooted plant, without leaves, excepting a slender short sheath or two at the base of each culm. The solanes tuberos glabres, which are in high estimation among all ranks of the Chinese, not only as a pot-root, but as a medicine. It is eaten either boiled or raw.

6033. Cultivation. "The ma-tai, pu-tai, or pi-tsi, of Abbé Grosier, grows in tanks; these are maintained for its reception almost the end of March. Then a tank being drained of its water, small plts are dug in its bottom; these are filled with human manure, and exposed to the sun for a fortnight; their contents are next intimately blended with the thin bottom of the tank, and the slips or roots of the plant deposited therein; the water is now returned to the tank, and the new crop of tubers comes to perfection by the 1st of September." (Roz. iii. 60.)

6034. The earth-almond, or rush-nut, (*Cyperus esculentus, L. Trian. Monog. L. and Cyperaceae, J. Soucet comeotile, Fr. and Zizelle di Terra, Ital.*) is a fibrous-rooted grass, with small round tubers hanging from it which taste like chestnuts or almonds. It is a native of Italy and Montpellier, and is cultivated in some parts of the south of Europe and Germany for food. The tubers are planted in spring, and taken up in October, and preserved for winter use in the manner of potatoes. It might probably be cultivated in this country in dry warm situations, or in a frame. (*Bon Jardinier.*)

6035. The cabale hibiscus.—*Hibiscus esculentus, L. Monoloph. Polyg. L. and Malvacceae, J. Gom- baud or Gombo, Fr.* This is a sove annual, a native of the West Indies, and introduced in 1825. A soft herbaceous stalk rises from three to five feet high, with crenate leaves, and axillary, pale sulphur-colored flowers, succeeded by capsules. These, in the West Indies and the south of France, are put green into soups, or eaten with butter. In the south of France it is cultivated in the open air for this purpose; and at Paris it is treated as we do the capiscum and love-apple. A similar treatment would, no doubt, succeed in this country.

6036. The arracacha, of the order of Umbelliferae, *J.* is a South American plant, said to resemble the *Apium* in habit; probably *Apium Americanum*, D., possibly *Ligusticum nova sp.* The main roots divide into four or five others, which grow to the size of cow's horns. These are used in the manner of potatoes by the inhabitants of Santa Fé and the Caracas. They are light, starchy, and easy of digestion. The plant is said to thrive best in the elevated regions of mountains, where the medium heat does not exceed 58° or 60°. (*Annals of Bot.* i. 400.) The name of this plant has not yet been determined, but, through the exertions of the Horticultural Society, it has recently been introduced to England, and will soon be submitted to examination and improvement.

6037. Other exotic esculents. To the above we might add, the *Dahlia*, recommended to be grown for its tubers by Thiebaud-de-Bernaud. The *Dolichos Soja*, a stove annual, the seeds of which form, or ought to form, the precedent to that name. The *carrot* and the *radish* are the names of the same vegetable, though the former is not a native of America. The earth-nut of South America (*Arctis hypogaea*), a stove annual, raised in a few places near Paris, on hot-beds, and then transplanted in the open air. The *Conocephalum replans*, a shrubby stove plant, grown in China, in trenches filled with water, and used as a spinaceous or oleaceous plant. The *Bauclia nigra*, and other species, stove biennials, used for the same purpose as the European *Trapa natans* and *litoralis*, both greenhouse annuals, but fruited by Lambert in the stove. (Hort. *Trans.* iv. 563.) The *T. natans* is grown in the ponds in Holland, according to Professor Martyn, and the nuts are used there as chestnuts both by men and hogs; and Neill informs us that the canal at Versailles is covered with the plant, and that the fruit is sometimes served up at table. These, and a variety of others, the curious cultivator will find noticed in botanical works and books of travels, and will enjoy greater satisfaction in discovering them himself than in finding them here ready named for his experimental inquiries.
Horticultural Productions which may be expected from a first-rate Kitchen-garden managed in the best Style.

6038. The sources of edible enjoyment afforded by a first-rate kitchen-garden are numerous and varied; and consequently a proprietor, who spares no expense on this department, ought to be informed of what he has a right to expect, subject, however, to the drawbacks of bad situations, uncertain seasons, and unforeseen accidents. Many gardeners object to tables of this kind, as leading to unreasonable expectations, disappointments, and quarrels, and as, in short, enlightening too much their employers. On this we shall only observe, that the more a proprietor requires, the more he must conform to the conditions on which alone these products are to be expected. As to the subject of enlightening masters, much might be said in its favor, and nothing founded in right reason against it. It is only by a knowledge of gardening that a master can distinguish a bad gardener from a good one; and only from this appreciation that a good gardener can be properly valued and rewarded. Community of knowledge must be better than no community at all. A man who employs a gardener as he does a tailor, merely to supply his wants, may look on him as a very convenient machine, and useful to have about his premises; but where a knowledge and taste for gardening exists in the employer, one point of union is formed between him and his servant, which must be productive of a certain degree of humanity, if not of mutual respect and consideration. It is only bad gardeners, therefore, that have to fear the dissemination of knowledge among their masters. In a work of this nature, however, in which the object is more to give the opinion of others than our own, we subjoin what M'Phail observes on the subject, which may be reckoned the opinion of most men of his order. "The book called Every Man his Own Gardener," he says, "gives a list of what fruits, &c., gentlemen may expect from their gardens in every month of the year; such a list not only of fruits, but of flowers and esculent vegetables, which nature, assisted by artificial means, is incompetent to produce in every month of the year in any country, in any degree of latitude under the sun; hence, from lists of this kind being given in books said to be written by practical gardeners, ariseth strife between masters and mistresses and their servant-gardeners." (Gard. Rem. Pref. xxviii.)

Sect. I. January.—The Productions arranged in the Order in which they have been treated in the preceding Chapters.

6029. Culinary Vegetables from the open garden or garden-stores. Jerusalem artichokes, turnip, carrot, parsnip, red-beet, kohlrabi, scorzonera, and salby, from the root-stores and seed-room. Spinage in mild seasons; also sorrel and white beet. Onions, leeks, garlic, shallots, and red-leaved onions, from the root-beds. Lettuce, endive, celery, American and winter cress. Parsley, the Italian and dired forms, &c. Thyme, sage, rosemary, lavender, from the open garden, and dried marjoram, savory, mint, fennel, &c. from the herb-room.

6030. Hardy Fruits from the open garden, orchard, or Fruit-room. Apples, pears, quinces, medlars, services from the fruit-room. Some plums and morelo cherries, carefully preserved on the trees. Some thick-skinned gooseberries, currants, and grapes, preserved on the trees. The same dried fruits of the same sort, from the same sort, branches hang in the fruit-room. Almonds, walnuts, pignuts, filberts, &c., in the same room. Some species of wild berries, &c. from the bushes, wild services, hips, haws, and sometimes a few cloudberries.

Sect. II. February.

6032. Culinary Vegetables from the open garden or garden-stores. Scotch or Edinburgh cabbage, savoy, horseradish, Brussels sprouts, &c., and, if a mild winter, cabbage-colovelets, broccoli. Haricots, beans, and soup-peas, from the seed-room. Potatoes, Jerusalem artichokes, turnip, carrot, parsnip, red-beet, kohlrabi, scorzonera, and salby, from the root-stores and seed-room. Spinage in mild seasons; also sorrel and white beet. Onions, leeks, garlic, shallots, and red-leaved onions, from the root-beds. Lettuce, endive, celery, American and winter cress. Parsley, if protected, horse-radish, and dried forced, dill, chervil, &c. Thyme, sage, rosemary, lavender, from the open garden, and dried marjoram, basil, &c. from the herb-room. Rhubarb-stalks from covered roots, anise, coriander, and caraway-seeds, from the seed-room; chervil, &c. from the herb-room; melanos, saffron, &c. Nettle and thistle tops; towards the end, sour-leaves, and, if a mild winter, sauce- alone. Mushrooms from covered ridges. Sea-belt preserved, and occasionally badder-dock.

6033. Hardy Fruits from the open garden, orchard, or Fruit-room. Apples, pears, quinces, medlars, services from the fruit-room. Some plums from branches hang in the fruit-room. Dried grapes and currents from branches hang in the fruit-room. Almonds, walnuts, pignuts, filberts, &c., in the same room. Some species of wild berries, &c. from the bushes, wild services, hips, haws, and sometimes a few cloudberries.

Sect. III. March.

6035. From the open garden, orchard, or Fruit-room. Apples, pears, quinces, medlars, services from the fruit-room. Some plums from branches hang in the fruit-room. Almonds, walnuts, pignuts, filberts, &c., in the same room. Some species of wild berries, &c. from the bushes, wild services, hips, haws, and sometimes a few cloudberries.
Sampthire and buds of marh-margold. Nettle, campion, thistle, bramble, barbuck, ox-tongue, sauce-alone, and other herbs; chicory, wild rocket, sea-belt, and other leaves. Mushrooms from the fruit-cellar, and from the herb-room; and other fungi from a fresh state; sea-belt preserved; and floating fungi picked.

1045. Hardy fruits from the open garden, orchard, or fruit-room.

The list may contain a few fruits from the fruit-cellar. Some dried fruits from the fruit-room. Almonds, walnuts, chestnuts, filberts, from the fruit-cellar.

1046. Culinary productions and fruits from the forcing department.

Yams.

1050. Culinary vegetables and fruits from the forcing department.

Mushrooms, pines, grapes, peaches, nectarines, figs, cherries, &c. Melons, cucumbers. Shadocks, oranges, lemons.

1053. Culinary vegetables from the open garden, or garden-stores.

Cabbages, turnips, carrots, radishes, swede, onions, parsnips, parsnips, parsley.

Rhubarb-stalks, rampion, frosted peas, carrots, radishes, cresses, peas, beans, mint, melons, cucumbers, cherries, plums, peaches, nectarines, apricots, peaches, melons, figs, cherries, apples, pears, plums, cherries, peaches, apricots, and other fruits.

1054. Hardy fruits from the open garden, orchard, or fruit-room.

Apples, pears, from the fruit-garden; and from the fruit-room; some from the fruit-cellar; some from the native habitats. Some from the fruit-room; some from the native habitats; and from the fruit-cellar. Some from the fruit-room; some from the native habitats; and from the fruit-cellar.

1055. Culinary vegetables and fruits from the forcing department.

Caterpillar, chives, garlic, and other herbs; conserved in covered ridges. Dulse, tangle, &c. as in June.

1056. Hardy fruits from the open garden, orchard, or fruit-room.

Apples, pears, from the fruit-garden; and from the fruit-room; some from the fruit-cellar; some from the native habitats. Some from the fruit-room; some from the native habitats; and from the fruit-cellar. Some from the fruit-room; some from the native habitats; and from the fruit-cellar.

1057. Culinary productions from the open garden, or garden-stores.

Cabbage, cauliflowers, broccoli. Turnips, carrots, radishes, swede, onions, parsnips, parsnips, parsley.

Parsley, purslane, mint, &c. Rhubarb. Mushrooms. A pinto occasionally; grapes, peaches, melons, cucumbers, cherries, figs, apples, pears, gooseberries, strawberries. Lemons, shuddocks, oranges, pomegranates.

Yams.
FLORICULTURE.

this class green or dried. Gourds and pumpkins, aromatic seeds, and dried herbs, as in September. Love-apple, caper-trees, eggplant, red cabbage, kidney bean. Meadow-sweet, and the other edible roots, and heath for brewing. All the sorts of edible fluff.

Sect. XI.

6069. Culinary vegetables from the open garden, or garden-stores. Cabbages, cauli-flowers, protected by frames; broccoli, Brussels sprouts, savoy, and broccoli. Dried kidney beans and peas, from the seed-room. Potatoes, turnips, carrots, winter radish, Jerusalem artichokes, red beet, skirt, salaty, and scorzonera, from the open garden or root-room. Beet-root, where protected. Onions, leeks, garlic, shallot, and scorzonera. Cabbage, radishes, celery. Endive, lettuce, winter cress, bokashi. Parsley, horse-radish, fennel, and dried chervil, &c. Thyme, sage, and rosemary, the others chiefly from the herb-room. Caraway, anise, and other aromatic seeds from the seed-room; the family herbs from the herb-room. Red cabbage. The edible roots, as in October. Sea-belt, badder-locks, and other species of fluff.

December.

6073. Culinary vegetables from the open garden, or garden-stores. Straburg cabbages, cauliflower, where preserved or protected, broccoli, savoy, Brussels sprouts, broccoli. Dried kidney beans for haricots; and savoy peas from the seed-room. Potatoes, turnips, carrots, winter radish, Jerusalem artichokes, red beet, skirt, salaty, and scorzonera, from the open garden or root-room. Beet-root, where protected. Onions, leeks, garlic, shallot, and scorzonera. Cabbage, celery, endive, lettuce, winter and American cress. Parsley, horse-radish, dried herbs, Thyme, sage, rosemary, lavender, &c., from the other dried. The anise and other aromatic seeds from the seed-room, and the herbs of the class from the herb-room. Red cabbage. Edible roots from the stores or pits. Preserved seeds, and when the weather admits of gathering, other edible fluff; the floating fluff in pickles.

BOOK II.

FLORICULTURE.

6075. Floriculture we consider as comprehending whatever relates to the culture and arrangement of vegetables, grown chiefly on account of their flowers, or as objects of taste or curiosity. The culture of flowers was long carried on with that of culinary vegetables, in the borders of the kitchen-garden, or in parterres or groups of beds, which commonly connected the culinary compartments with the house. In places of moderate extent this mixed style is still continued; but in residences which aim at any degree of distinc tion, the space within the walled garden is confined to the production of objects of domestic utility, while the culture of plants of ornament is displayed in the flower-garden and the shrubbery. These, under the general term of pleasure-ground, encircle the house in small seats, and on a larger scale embrace it in one or more sides; the remaining part being under the character of park-scenery. Many of the most interesting plants belonging to this branch of culture are natives of warm climates, and require the protection of glass and artificial heat. On a limited scale, such plants are grown in the culinary-forcing houses, or in green-houses, or botanic stoves, connected with the others in the kitchen-garden. In complete residences, however, the culture of exotics forms a distinct department of ornamental horticulture, and the hot-houses requisite for this purpose are placed in the flower-garden, or variously arranged within the precincts of the pleasure-ground. In both departments, separation is attended with the usual advantages resulting from a division of skill, labor, and effect. Floriculture is obviously of limited interest and utility, compared to horticulture; much less has accordingly been written on it, and our view of modern practice will, therefore, be proportionately brief. The order adopted, is the formation, planting, and general culture of the flower-garden; the formation, planting, and general culture of the shrubbery; the design and general culture of the floricultural hot-houses; the catalogue of plants and trees used in ornamental horticulture; and, lastly, the monthly table of floricultural productions.

chap. I.

of the Formation of the Flower-garden.

6076. The situation of the flower-garden, as of every department of floriculture, should be near the house, for ready access at all times, and especially during winter and spring.
when the beauties of this scene are felt with peculiar force. "The flower-garden," Neill observes, "should form an ornamental appendage to the mansion, and be easily accessible in all kinds of weather. There is no objection to its being seen from the windows of the house: on the contrary, this is sometimes considered as desirable." Nico., as we have seen (2382.), approves of having the various gardens of a place combined, and placing them at no great distance from the house; and Repton strongly recommends this practice.

6077. Abercrombie says, "While the kitchen-garden is concealed by buildings or plantations, the flower-garden and pleasure-ground should stand conspicuously attached to the family residence. When the horticultural establishment includes a conservatory, it is proper to have it in sight, and connected with the ornamented grounds; because the style of such a building, the plants within, and the scene without, under a tasteful arrangement, harmonise in character and effect. The botanic-garden, the range of stores, and all the departments, a visit to which renders a walk about the grounds pleasing and interesting, should be at hand."

6078. The author of the Florist's Manual confines her observations to the "construction of that humble flower-garden," which she calls "the common or mingled flower-garden." "This," she says, "should be situated so as to form an ornamental appendage to the house, and where the plan of ground will admit, placed before windows exposed to a southern or south-east aspect; and although to this position there may appear the objection of the flowers turning their petals to the sun, and consequently from the windows, this predilection in the tribe of Flora for the rays of that bright luminary, will produce the same effect in whatever place our flowers may be situated, when in the vicinity of a building, as they invariably expose the front of their corols to the lights from which both the petals of flowers, and the leaves of plants are believed to derive material essential to their existence." She adds, "when apart from the house, the mingled flower-garden may be introduced with great advantage, if situated so as to form a portion of the pleasure-ground: in this case it should not be distinct from the house, but so contrived as to terminate one of the walks of the house shrubberies." (Flor. Man. p. 10. 15.)

6079. To place the flower-garden south-east or south-west of the house, and between it and the kitchen-garden, is in general a desirable circumstance. In a design for a villa farm (fig. 539), supposing the entrance-front of the house (a), to face the north-west, then the farm-offices (b), horse-pond (c), &c. may be placed to the north-east; the kitchen-yard (d) and livery-stable-yard (e) to the south-west: against these may be placed the exotic hot-houses, looking to the flower-garden (f), and beyond this the American garden (g), and lastly, the kitchen-garden (h), and walk through the farm (l). If concealed approaches to the farm and stable-offices (c, n) and from the kitchen-garden to the kitchen (h, e, a) be contrived, such an arrangement will be found to combine both elegance and economy, and to admit of bringing the wire fence (m), which separates the mown from the field land, near the house, without being unsightly: a desirable object in farm villas, as it saves mowing, and increases pasturage.

6080. In exposure and aspect, the flower-garden should be laid out as much as possible on the same principles as the kitchen-garden (2390.), not only on account of the advantages to be derived from the full influence of the sun during winter on the hot-house department, but also for the better enjoyment of the open air scenes, in weather favorable for walking out of doors. It should not be naturally low in surface, nor of a wet retentive soil, nor rendered damp and gloomy by surrounding high trees, or lofty walls or buildings. If it happen that a house be nearly surrounded by a flower-garden, the variety of aspect thence afforded will be favorable to the continuance of the bloom of our flowers, far beyond what can be obtained if confined to a southern exposure. South, south-east, and east, are the aspects most advantageous to the growth of flowers; and, possessing these varieties of exposure, the bloom of a garden may be protracted some weeks beyond the time it could be preserved under a single aspect.

6081. The extent of the flower-garden depends jointly on the general scale of the residence, and the particular taste of the owner. If any proportion may be mentioned, perhaps, a fifth part of the contents of the kitchen-garden will come near the general average; but there is no impropriety in having a large flower-garden to a small kitchen-garden or mansion, where the taste of the owner leads to such a deviation from common rules. As moderation, however, is generally found best in the end, we concur with the author of the Florist's Manual, when she states, that "the compass of ground appropriated to flowers must vary according to the size of the place of which that ground forms a part, and should in no case be of great extent. If the form of ground, where
a parterre is to be situated, is sloping, the size should be larger than when a flat surface, and the borders of various shapes, and on a bolder scale, and intermingled with grass; but such a flower-garden partakes more of the nature of pleasure-ground than of the common parterre, and will admit of a judicious introduction of flowering shrubs." "To cover twenty acres with mere flowering plants," Abercrombie observes, "producing nothing esculent in the root, leaves, or fruit, would be puerile and ridiculous, as it would exceed the moderation with which nature scatters her ornaments." (Pract. Gard. 338.)

6082. Shelter is equally requisite for the flower as for the kitchen garden, and, where naturally wanting, is to be produced by the same means, viz. planting. The plantation on the side next the garden, should begin with the lowest shrubs, and rise in gradation to the trees, which, unless on the north, or very exposed points, should not be of the tallest kinds. A few elegant shrubs, and one or two trees may be scattered through the scene, either in the dug compartments or in the turf-glades, for the purposes of shelter and shade as well as ornament; but in general, much of either of the two former qualities are highly injurious both to the culture of flowers, and the thick closeness of turf; besides rendering the garden unfit to be resorted to in the winter and spring seasons. Sometimes an evergreen-hedge will produce all the shelter requisite, as in small gardens composed of earth and gravel only (fig. 541.); but where the scene is large (fig. 540.), and composed of dug compartments (a), placed on lawn (b) the whole may be surrounded by an irregular border (c) of flowers, shrubbery, and trees.

6083. Soil. Most of the hardy herbaceous flowers, and the deciduous and evergreen ornamental shrubs, will succeed in a soil of common good qualities, moderately light and mellow. Negatively, the ground should not be excessively strong and clayey; and mere gravel is very intractable. (Abercrombie.)

6084. Nicole observes, that flowers in general "will thrive very well in common garden-earth of a middling texture, if broke fine, to the depth of a foot. Some, no doubt, do better in light than in heavy soils; and the contrary: and others do best in rich humid earth. Bulbous flowers, in general, do best in light sandy earth; though some require a stronger and a richer soil. In general, the soil for these should be formed at least eighteen inches deep, and should be made very fine by the spade, or be put through a coarse screen." In parterres where the finer flowers are cultivated, a variety of soils will be required according to the nature of the plants, as rich sandy loam for bulbs, loamy earth for the primula tribe, bog-earth for American plants; and hence it follows, that, provided the sub-soil be dry, the nature of the surface-stratum is of the less consequence.

6085. Surface. Where the extent is small, and the plants grown to be chiefly florists' flowers, or other select kinds, in beds separated by gravelled paths, a level or gentle and uniform slope will be found most suitable; but where the limits are more extensive, and turf and shrubs are introduced, a wavy surface, either naturally or rendered so by art, will have much the best effect. "In reclusc scenes immediately under the eye, art may create a sort of miniature of beautiful ground. Man is but a puny object compared to those of inanimate nature. He may overlook a distant hill, separated by low ground; but a mound of less than three yards in height, placed near the eye, confines the view, and all other objects being shut out, acquires, if apparently a work of nature, a degree of importance in his imagination: winding walks, four feet below the original surface, will supply earth for accompanying them by wavy hills or swells eight feet high. If these hills and swells are formed and contrived so as to produce a varied and natural-like whole, with every change of position, a very suitable basis will be raised for a picturesque shrubbery or flower-garden. It was to this sort of art that Pope's garden, at Twickenham, was indebted for so great a variety of beauties in a small space; and the flower-garden at Lord Harcourt's, at Nuneham, was laid out under the eye of Mason the poet, on the same principle." (Ed. Ency. art. Landscape Gardening.)
6086. Water. This material, in some form or other, is as essential to the flower as to the kitchen garden. Besides the use of the element in common culture, a pond or basin affords an opportunity of growing some of the more showy aquatics, while jets, dropping-fountains, and other forms of displaying water, serve to decorate and give interest to the scene. Besides choice aquatics, the ponds or basins of flower-gardens may be stocked with the gold-fish (Cyprinus auratus), and will serve as a hybernaculum for that elegant and interesting animal the tree-frog (Rana arborea), so amusing in the gardens of the south of Germany.

6087. The form of a small garden (fig. 541.) will be found most pleasing when some regular figure is adopted, as a circle, oval, octagon, crescent, &c.: but where the extent is so great as not readily to be caught by a single glance of the eye, an irregular shape is generally more convenient, and it may be thrown into agreeable figures, or component scenes, by the introduction of shrubs so as to subdivide the space. "Either a square or an oblong ground-plan," Abercrombie observes, "is eligible; and although the shape must be often adapted to local circumstances, yet, when a garden is so circumscribed that the eye at once embraces the whole, it is desirable that it should be of some regular figure."

6088. Nicol says, "a variety of forms may be indulged in, without incurring censure; provided the figures be graceful, and not in any one place too complicated. An oval is a figure that generally pleases, on account of the continuity of its outlines; next, if extensive, a circle. Next, perhaps, a segment in form of a half-oval, or the larger segment of an oval. But hearts, diamonds, triangles, or squares, if small, seldom please. A simple parallelogram, divided into beds running lengthwise, or the larger segment of an oval, with beds running parallel to its outer margin, will always please." Neil concurs in this opinion.

6089. The author of Hints on the Formation of Gardens, &c. says, "a symmetrical form is best adapted to such parterres as are small and may be comprehended in one view; and an irregular shape to such as are of a considerable size, and contain trees, shrubs, statues, vases, seats, and buildings."

6090. Boundary fence, or screen. Parterres on a small scale may be enclosed by an evergreen hedge of holly, box, laurel, privet, juniper, laurustinus, or Irish whin (Ulex europaeus, var. a.); but irregular figures, especially if of some extent, can only be surrounded by a shrubbery, such as we have already hinted at (6082.) as forming a proper shelter for flower-gardens.

6091. Abercrombie says, "for the enclosure, a wall or close paling is, on two accounts, to be preferred on the north side; first to serve as a screen, and to afford a warm internal face for training rare trees. When one of those is not adopted, recourse may be had to a fence of white thorn and holly," &c. (Pract. Gard. 330.)

6092. Rustic fences formed of shoots of the oak, hazel, or larch, may often be introduced with good effect both as interior and surrounding barriers. (fig. 542.)

6093. Laying out the area. This is the most difficult part of the business, and is not to be excelled in without a considerable degree of taste and experience. In laying out
the area of the kitchen-garden, its destination being utility, affords in all cases a safe
and fixed guide; but the flower-garden is a matter of fancy and taste, and where these
are wavering and unsettled, the work will be found to go on at random. As flower-
gardens are objects of pleasure, that principle which must serve as a guide in laying them
out, must be taste. Now, in flower-gardens, as in other objects, there are different kinds
of tastes; these embodied are called styles or characters; and the great art of the designer
is, laying fixed on a style, to follow it out unmixed with other styles, or with any de-
viation which would interfere with the kind of taste or impression which that style is cal-
culated to produce. Style, therefore, is the leading principle in laying out flower-gardens,
as utility is in laying out the culinary-garden. As subjects of fancy and taste, the styles
of flower-gardens are various. The modern style is a collection of irregular groups and
masses, placed about the house as a medium, uniting it with the open lawn. The ancient
geometric style, in place of irregular groups, employed symmetrical forms; in France,
adding statues and fountains; in Holland, cut trees and grassy slopes; and in Italy,
stone walls, walled terraces, and flights of steps. In some situations, these characteristics
of parterres may with propriety be added to, or used instead of the modern sort, especially
in flat situations, such as are enclosed by high walls in towns, or where the principal
building or object is in a style of architecture which will not render these appendages
incongruous. There are other characters of gardens, such as Chinese, which are not
widely different from the modern; the Indian, which consists chiefly of walks under
shade, in squares of grass, &c.; the Turkish, which abounds in shady retreats, boudoirs
of roses and aromatic herbs; and the Spanish, which is distinguished by trellis-work and
fountains: but these gardens are not generally adapted to this climate, though from con-
templating and selecting what is beautiful or suitable in each, a style of decoration for
the immediate vicinity of mansions might be composed, greatly preferable to any thing
now in use.

6094. Abercrombie, Nicol, and most practical gardeners, seem not to understand the subject of style,
and their rules amount to little more than that of subdividing the area by paths in different directions.
The former author says, "If a piece of ground be set apart for the cultivation of flowers, in what style
should it be laid out? This may vary with the quantity of surface, and the object of the cultivator. In
the first place, carry a border round the garden, nowhere narrower than three or four feet, unless it may
be proper to contract its breadth under the windows of the house; or unless there be a green hedge,
on any side, rooted in the level of the garden, which might be expected either to draw the earth, or
to encroach on the small plants, in which case flowering shrubs in little slips of mould would do better
than dwarf-stemmed flowers. In contact with the surrounding border, may be either a grass-plot or a
gravel-walk. The latter is most convenient for approach at all seasons. If the ground be at all dilated,
handsome walks, crossing or leading to the centre, will be also requisite: let the principal walks be five
or six feet in breadth. The interior of the garden is usually laid out in oblong beds, three or four feet
wide, with intervening alleys, two feet wide, or from that down to twelve inches, when it is intended to
abstract as little space as possible from the cultivation of the flowers; or, the same end may be obtained
by circular or oval beds, with smaller compartments between, of such a form as will leave the alleys of
one regular width." (Pract. Gard. 340.)

6099. According to Nicol, the laying out of flower-gardens is a "matter very much of fancy. Too
many gravelled alleys offend the eye, especially if they be much twisted, or run across; as it comprehends
the whole at once. Their breadths should be proportioned to that of the beds; nor should they be much

544
sunk; seldom more than an inch; otherwise they have a bad effect, and look rather like furrows than alleys. They may be edged with box, yew, or hollies, with violets, gentianella, or thrift, according to fancy. But the creation of whatever it be, should be kept low, thin, and neat. It should seldom be allowed to rise two inches high, or spread two inches wide. "A linear box-edging always pleases, if kept quite close and connected." (Kal. 458.)

335. The author of the Florist's Manual, though she confines her directions to one style, has much more correct ideas on the subject than our practical authors. "It is more difficult," she says, "than may at first appear, to plan, even upon a small scale, such a piece of ground, nor, perhaps, would any but an experienced scientific eye be aware of the difficulties to be encountered in the disposal of a few shaped borders to turf; the materials consist in arranging the different parts so as to form a connected glow of color, to effect which it will be necessary to place the borders in such a manner that when viewed from the windows of the house, or from the principal entrance into the garden, one border shall not intercept the beauties of another, nor in avoiding that error, produce one still greater, that of vacancies between the borders forming small avenues by which the whole is separated into broken parts, and the general effect lost. Another point to be attended to, is the just proportion of green turf, which, without nice observation, will be too much or too little for the color with which it is blended; and, lastly, the breadth of the flower-borders should not be greater than what will place the roots within reach of the gardener's arm without the necessity of treading upon the soil, the mark of footsteps being a deformity wherever it appears amongst flowers." (Flor. Man. 15.)

6099. The green-house or conservatory is generally placed in the flower-garden, provided these structures are not appended to the house. In laying out the area, a fit situation must be allotted for this department of floriculture, and the principles of guidance laid down in treating of the situation of the culinary hot-houses (2475.) require here also to be applied. Some recommended the distribution of the botanic hot-houses throughout...
the flower-garden or pleasure-ground; but we are decidedly of opinion, that much the best effect is produced when they are connected together in one scene. By the other mode they may form objects agreeable enough to look at externally; but to derive the full effect of their internal beauties, it appears to us that they must be examined in succession and without interruption. No arrangement can be better, in our opinion, than to connect the whole of the botanic hot-houses with the mansion as an introductory scene to the flower-garden. This was Repton's favorite mode, of which, among other examples, he has left that of Ashridge Park. (fig. 546.) Here, to the original lawn and pleasure-ground (1), he made an addition in the same style (2), uniting by walks the following interesting scenes. The botanic stoves and paved terrace (3); broad-sanctuary and holy-well (4); pomarium and winter walk (5); the monk's garden (6); arboretum of exotic trees (7); magnolia and American garden (8); embroidered parterre (9); grotto and garden for rock-plants (10); cabinet de verdure (11); mount garden (12); rosarium and fountain (13); connecting and interior walks (14); open terrace and exterior walks (15).

6100. In particular situations, as where the prospect and space are both confined, the plant hot-houses may embrace the house or the court-yard on two or more sides. In a case of this kind, which occurred in our practice (fig. 547.), a large conservatory (a) and aquarium (b) were connected with the library (k):

from the conservatory, a green-house (c) led to an aviary (d), and this was connected with a house for standard peach-trees, with vines as climbers (e), by two plant-stoves (e and f). The furnaces were placed in the court-yard (l), and attended from the stable-yard (h), without interfering with the house (l), or the flower-garden (m). The elevation of such a range (fig. 548.) does not pretend to architectural or picturesque beauty; but it is such as is best suited for the culture of plants; and from the peculiarity of the situation it is seen from no point beyond the limits of a very moderate-sized flower-garden.

6101. According to Noll, a green-house, conservatory, and stove should form prominent objects in the different parts of the flower-garden. The author of the Florist's Manual recommends a spring-conservatory, annexed to the house, consisting of borders sheltered by glass, and heated only to the degree that will produce a temperature, under which all the flowers that would naturally bloom between the months of February and May might be collected, and thence be enabled to expand their beauties with vigor. (Flor. Man. v. 233.)
6102. According to Nicol, "the most proper situation for the green-house and conservatory, in an extensive and well laid out place, is certainly in the shrubbery or flower-garden; and not, as they are very generally to be found, in the kitchen-garden, combined with the forcing-houses. In smaller places, no doubt, they must be situated so as to suit other conveniences; and we often find them connected with the dwelling-house. In this latter way they may be very convenient, especially in the winter season, and may answer for keeping many of the hardy kinds of exotics; but it is seldom they can be so placed and constructed, on account of their connection with the building, as to suit the culture of the finer sorts, and bring them to a flowering state. Such may rather be termed green-rooms, as being connected with the house." (Kohl. 53.)

6103. Abercrombie says, "A green-house may be made a very ornamental object as a structure; its situation is, therefore, usually in a conspicuous part of the pleasure-ground, contiguous to the family residence. The front of the building should stand directly to the south, and the ends have an open aspect to the east and west." (Pract. Gard. 55.)

6104. Flower-nursery, and pits for forcing flowers. To every complete flower-garden and shrubbery, a piece of ground should be set apart in a convenient and concealed situation, as a reserve-ground, or nursery of flowering plants and shrubs. The situation should, if practicable, be behind and near to the range of hot-houses, and it may at the same time include the pits for forcing flowers, and the hot-bed department of the flower-garden. Here plants may be originated from seed, cuttings, pipings, and a proper stock kept up, partly in beds and partly in pots, for more easy removal, to supply blanks, and in the more select scenes, to replace such as have done flowering. No flower-garden can be kept in complete order without a nursery of this description; nor could the management of some sorts of florists' flowers, as the auricula, during the latter part of summer and winter, the carnation, &c. be well carried on without it. Here they may be grown, and, when in bloom, exhibited in proper stages in the main garden.

6105. Walks. In most styles of parterres these are formed of gravel; but in the modern sort (fig. 549.), which consist of turf, varied by wavy dug beds (1 and 2), and surrounded by shrubbery, they are sometimes dispensed with. Such a flower-garden is recommended by the author of the Florist's Manual, as suitable for the "midst of pleasure-ground," and the beds "peculiarly adapted to the advantageous exhibition of flowers." The general length of the beds she recommends to be from twenty-three to twenty-five feet, and the width in the broadest part, about four feet; the grass to be five or six feet wide between the beds, that it may be conveniently mown and rolled; all the beds a good deal raised, and a tree (3) placed at the entrance (4) of light and rather pendulous foliage, and pruned to form a high stem. "If the space of grass between the borders appear too great, it may be lessened by baskets of ever-blowing roses, carnations, or any other plants; and these baskets may be formed by circular beds, surrounded by cast-iron, made to resemble the open edges of a basket, and painted of a very dark-green color." (p. 6.)

6106. In extensive and irregular parterres, one gravel-walk, accompanied by broad margins of turf, to serve as walks by such as prefer that material, should be so contrived as to form a tour for the display of the whole garden. There should also be other secondary interesting walks of the same width, of gravel and smaller walks for displaying particular details. The main walk, however, ought to be easily distinguishable from the others by its broad margins of fine turf. In general the gravel is of uniform breadth throughout the whole length of the walk; but in that sort of French parterres which they call parterres of embroidery (fig. 550.), the breadth of the gravelled part (a) varies like that of the turf. Such figures, when correctly executed, carefully planted, judiciously intermixed with basket-work, shells, party-colored gravels, &c. and kept in perfect order, are highly ornamental; but very few gardeners enter into the spirit of this department of their art. The French and Dutch have long greatly excelled us in the formation of small gardens, and the display of flowers; and whoever wishes
to succeed in this department ought to visit Amsterdam, Antwerp, Brussels, and Paris; and consult the old French works of Mallet, Boyceau, Le Blond, &c.

5107. Edgings. In parterres where turf is not used as a ground or basis out of which to cut the beds and walks, the gravel of the latter is disparked from the dug ground of the former by edgings or rows of low-growing plants, as in the kitchen-garden. Various plants have been used for this purpose; but, as Neill observes, the best for extensive use is the dwarfish Dutch box, kept low and free from blanks. Abercrombie says, "Thrift is the nearest small evergreen next to box. In other parts, the daisy, pink, London-pride, primrose, violet, and periwinkle, may be employed as edgings. The strawberry, with the runners cut in close during summer, will also have a good effect; the wood-strawberry is suitable under the spreading shade of trees. Lastly, the limits between the gravel-walks and the dug-work may sometimes be marked by running verges of grass kept close and neat. Whatever edgings are employed, they should be formed previous to laying the gravel."

5108. Basket-edgings. Small groups near the eye, and whether on grass or gravel, may be very neatly enclosed by a worked fence of basket-willows from six inches to a foot high. These wicker-work frames may be used with or without verdant edgings; they give a finished and enriched appearance to highly polished scenery; enhance the value of what is within, and help to keep off small dogs, children, &c. Abercrombie scarcely approves of them. He says, "Where round or oval parterres stand on a ground of lawn, it is a prevailing fashion to surround them with what are termed baskets. These are commonly made either of wood or cast-iron; those of the latter material of course are durable; and the others, if painted, and removed under shelter in winter, will last ten or twelve years. Novelty is all attractive; and when men have walked as far as they can in the path of nature for principles of embellishment, for the sake of novelty they will walk back again. A bed of flowers and shrubs within a basket looks very much like a large bouquet. What is artificial, should have some use. Where cattle are to be kept off, a basket is serviceable." (Pr. Gard. 454.)

5110. To assist in the invention of figures for flower-gardens, the simple but ingenious contrivance (fig. 551) invented by Professor Bradley may be made use of. It consists of two plates of looking-glass, of any convenient size, furnished with wooden backs, so as to admit of their being hinged (a). One part of a circular figure being then drawn on paper (b, c), the frames are to be opened the width of the figure (b, c, d), and placed on edge so as to include it, when the form will then be so multiplied by the looking-glass as to complete the circle. The kaleidoscope may also be resorted to, of which this instrument of Bradley's is supposed to be the origin or prototype.

CHAP. II.
Of Planting the Flower-garden.

5110. The manner of planting the herbaceous plants and shrubs in a flower-garden depends jointly on the style and extent of the scene. With a view to planting, they may be
divided into three classes, which classes are independently altogether of the style in which they are laid out. The first class is the general or mingled flower-garden, in which is displayed a mixture of flowers with or without flowering-shrubs according to its size. The object in this class is to mix the plants, so that every part of the garden may present a gay assemblage of flowers of different colors during the whole season. The second class is the select flower-garden, in which the object is limited to the cultivation of particular kinds of plants; as, florists' flowers, American plants, annuals, bulbs, &c. Sometimes two or more classes are included in one garden, as bulbs and annuals; but, in general, the best effect is produced by limiting the object to one class only. The third class is the changeable flower-garden, in which all the plants are kept in pots, and reared in a flower-nursery or reserve-ground.

As soon as they begin to flower, they are plunged in the borders of the flower-garden, and, whenever they show symptoms of decay, removed, to be replaced by others from the same source. This is obviously the most complete mode of any for a display of flowers, as the beauties of both the general and particular gardens may be combined without presenting blanks, or losing the fine effect of assemblages of varieties of the same species; as of hyacinth, pink, dahlia, chrysanthemum, &c. The fourth class is the botanical flower-garden, in which the plants are arranged with reference to botanical study, or at least not in any way that has for its main object a rich display of blossoms. On each of these gardens, or manners of arranging plants grown for their beauty or curiosity, we shall offer some remarks.

6111. The mingled flower-garden, or border, is by far the most common; it is what every gardener attempts at in planting his flower-borders, and the aim of the greater number of such as form parterres, or separate scenes for the culture of flowers, seldom goes further. The object here is to display a gay assemblage of colors during the season of flowers, without much regard to variety of form or diversity of character in these flowers, or the plants that produce them. The great art, therefore, in this kind of flower-border, is to employ such plants as produce large heads, or masses of flowers; to plant an equal number of every color, and such a variety in regard to time of flowering as may afford some of every color in flower from February to October. This object does not require a great variety so much as a judicious selection; for, supposing the number four to include all the colors of flowers, and one sort to continue in bloom a month, then for nine months of the year, viz. from February to October inclusive, only thirty-six sorts will be requisite to commence, as it were, the pattern of the border. Much more may be effected by a few sorts than by a great number, for the greater the number of sorts introduced in the pattern above thirty-six, supposing it correct that one sort continues in bloom a month, the greater the blank spaces that must remain between the plants in bloom. A moderate number of select sorts, or of what are called border-flowers, and that number selected equally from the different colors, and the sorts in bloom in the nine months of blooming season, is what demands the exclusive attention of whoever would plant a mingled border, or flower-garden. It has been frequently observed that flower-gardens have been on the decline for the last half century; and the cause of this appears to have been the influx of new plants during that period, by which gardeners have been induced without due consideration to be more solicitous about rarity and variety, than well disposed colors and quantity. The same error, and from the same cause, has prevailed, during the above period, in the planting of shruberies and tree-plantations.

612. Abercrombie, Nicol, and other practical gardeners, seem to have no distinct ideas on the subject of arranging flowers in flower-gardens; but the authors of Hints on laying out Gardens, and of the Florist's Manual, have viewed the subject in its proper light. Nicol also has some judicious observations on the subject. He says, "the plants are arranged in mingled flower-borders, partly according to their size, and partly according to color. The tallest are planted in the back part, those of middling size occupy the centre, and those of humble growth are placed in front. The beauty of a flower-border, when in bloom, depends very much on the tasteful disposition of the plants in regard to color. By intermingling plants which flower in succession, the beauty of the border may be prolonged for some weeks. In a botanic-garden the rarest, most beautiful, and most changeable, in regard to color, may be preserved in the same border; but in the common flower-garden a plant, if deemed ornamental, may be often repeated with the best effect; nothing can be finer, for example, than to see many plants of double scarlet lychnis, double sweet-william, or double purple Jacobea."

613. The author of Hints, &c. remarks "that the beauty of parterres depends more on the materials with which they are planted than on their form; and that the prevailing error consists in crowding them with all sorts of trees and plants at random, or filling them entirely with rare species, which will ever want one principal source of beauty — health." In the Florist's Manual it is observed, that "the fashionable novice, who has stored her borders from the catalogue of some celebrated name with variety of rare species; who has procured innumerable rose-trees, chiefly consisting of old and common sorts, broken by a few by new names; who has set aside a part of her garden for bulbs, and only placed them in bog soil, with their names painted on large-headed pegs, becomes disappointed when, instead of the brilliant glow of her more humble neighbor's parterre, she finds her own distinguished only by paucity of color, and fruitless expenditure. Variety of species, bog borders, largely lettered in good taste, they will not procure a gay flower-garden; and the simple cause of the general failure in this particular is the prevalent solicitude for rarity and variety, in preference to well-blended quantity; as, without the frequent repetition of the same plant, it will be in vain to attempt a brilliant flower-garden, and, in the judicious mixture of every common color, the art of procuring it consists. Hence the foundation thus laid, the solicitude of those who wish to complete the superstructure must not be for rare species, but for new color, so that the commonest primula which presents a fresh shade of red, blue, yellow, &c. ought to be esteemed more valuable than the most rare American plant which does not bring a similar advantage. In the formation of that assemblage of
flowers, which may be distinguished by the term of 'The Mingled Flower Garden,' it is essential that the separate parts should, in their appearance, constitute a whole; and this appearance is not incompatible with any form into which the ground may be thrown, if attention be given to the manner of planting. In some gardens this appearance of a whole is entirely destroyed by the injudicious taste of setting apart distinct borders for pretty effect, and painting the picture with flowers; also for different species of bulbs, as anemones, ranunculuses, hyacinths, &c.; these distinct borders, although beautiful in themselves, break that whole which should always be presented to the eye by the mingled flower-garden, as single beds of plants can only, from their peculiarity, introduce a mass of decaying leaves when the glow of their petals is no more. The reverse of this mode of planting is essential to the perfection of the mingled flower-garden, in each border of which there should be, at least, two of every species; but the precise number must be regulated by the force of color, and the relative position of the borders. It will be advisable always to have a copy of the garden presents itself, the eye should not be checked by the failure, in any part of it, of the prevalent colors of the season." (p. 5)

614. Hogg, who may be considered as the unprefaced observer of the different tastes in disposing of flowers, remarks: 'We are apt to ridicule the Dutchman, as well as the imitators of him here at home, who divide their gardens into small beds, or compartments, planting each with separate and distinct flowers; we ridicule the plan, because it exhibits too great a sameness and formality; like a mingled mass of flowers we believe they lose the power to please, because they want variety. It must undoubtedly be acknowledged, that a parterre, no matter in what form, whether circular or square, elliptical or oblong, where all the shrubs, plants, and flowers in it, like the flowers of a tastefully arranged bouquet, are variously disposed in neat and regular orders, according to a strict plan, and carefully rendered, is a delight to the eye, and a general imitation. Yet still in some particular cases I am disposed to copy the Dutchman, and even I would have my bed of hyacinth distinguish, my tulips distinct, my anemones, my ranunculuses, my mints, my carnations distinct, and even my beds of hollyhocks, double blue violets, and dwarf-larkspurs distinct, to say nothing of hedge-rows of different sorts of roses. Independent of the less trouble you have in cultivating them when kept separate, you have beauty in masses, and you have likewise their fragrance and perfume so concentrated, that they are not lost in air, but powerfully inhaled when you approach them. A mixture is a dish honied of this modern mania, and of contemplating this 'beauty in masses.' She adopted this style of gardening at her late residence on the Harrow-road. Her favorite flower was the viola amena, the common purple heart's-ease, and this she set with unerring prudence all around her garden. Her garden was remarkable in another respect, and which with great propriety may be styled a garden of evergreens, which, together with a few deciduous shrubs, were of the most sobri, sable, and gloomy mass, such as box-trees, fir, privet, phillyrea, arbor vitae, holly, cypress, the red cedar, laurel, Irish ivy, bay-tree, arbutus, spurge-laurel, &c. The only part of her garden, the species of which are each a separate department in herbaceous gardening, where the pleasing association of ideas in beholding these retain their green verdure and clothing, at a time when the rest of the surrounding trees were strip! naked and bare." (Tr. on Flowers, 69.)

615. To give an example of the manner in which a bed or border in the modern style, suppose the various colors of flowerers may be all included under the four common colors, red, white, blue, and yellow; that for the time of blowing, we allow February and March as one division, March and April as a second, May and June as a third, July as a fourth, August as a fifth, and September and October as the sixth and last. Then, since there is a degree of similarity in the flowering of these four periods, it is to be supposed that, at any time, the eye of the spectator, and the tallest at the back in regular gradation. Mark out the border in rows lengthways and across, so as each plant may stand in the angle of a square, whose side is, say, eighteen inches. Then begin at the first row (fig. 532, a), and fix on the order in which the plants are to be placed as respects their time of flowering. To distribute the plants in flower at one time as equally as possible over the border, the order of 1, 6, 3, 5, 2, 4, will, it is believed, be found the best. Next, fix as to the order of colors; and here it is of little consequence what order is fixed on, provided that order be maintained throughout the border: say that we adopt the order of red, white, blue, and yellow; then the flowers should be to be of the same color. Next, spread the plants will stand thus: 1r. 6w, 3b, 5y, 2r, 4w; that is, a red flower to come into bloom in February and March; next to it, a white flower to come into bloom in September and October; then, a blue flower to come into bloom in March and July, and a yellow flower to come into bloom in August; the order, or the colors of flowers, 1r, 6w, 3b, 5y, 2r, 4w, form a row. The second, third, and fourth rows, (6r, 3d) are to be arranged in the same way, observing, however, not begin with the same month and color for the sake of more effectually mingling the times of flowering and color of the flowers. Where rows or other shrubs are to be introduced, a plant must be omitted, which, however, should not be allowed to derange the order of the rest.

552

616. If a double border, with a walk on each side (fig. 553, a to k) a bed-group, or compartment on a lawn, to be viewed on all sides, is to be planted, then it is only necessary to fix on the number of rows, and to keep the lowest plants in the inner circle, adhering to the rows in order, and of course giving the plants or to any order that may be fixed on, and inserting shrubs in lieu of plants where it may be deemed advisable.

517. Borders in flowers should always be planted in rows, in some regular form, and that this appliance may most aptly keep off all arrowy side-shots and straggling stalks, and reducing the bulk of plants which grow too fast. Every approach to irregularity and a wild, confused, crowded, or natural-like appearance, must be avoided in gardens avowedly artificial.

518. With four colors, four sizes, and six degrees of coming out at once, a gardener may be confounded with ninety-six different plants, and the pattern may be repeated like the border of any work of art ad infinitum; but it is also evident, that it may include any number of species, provided these have the desired requisites of height, color, and time of flowering; the second and every successive repetition of the pattern being made up of the same, it may be introduced without any considerations of time and colors of flowering required for the first example of the pattern. The safest way, however, as we have
already observed, is to adopt but a moderate number of species, and those of the showy sorts that have numerous varieties, and are of hardy vigorous growth. A suitable list for this purpose is given in the floricultural catalogue, under the head of Border Flowers, and the reader may increase it at pleasure from the Prodrums of Page.

6119. The select flower-garden being limited to one kind, or class, of plants, is comparatively simple as far as respects planting. It may be devoted to florists' flowers, as the hyacinth, tulip, pink, auricula, &c.; to select flowers, as the dahlia, paony, chrysanthemum, &c.; to annuals, hardy, half hardy, and tender; to American or bog-earth shrubs and plants; to any natural order, as the bulbous-rooted tribe; or to spring, summer, or autumn flowers, &c.

6120. Florists' flowers and select flowers are planted in beds or compartments of carefully prepared soil, and the arrangement in the beds is generally conducted on the principle of mixing the colors and shades of color as much as possible. As the plants being of the same species generally grow at the same time, and the same sort of flower at the same time, no particular attention is requisite in these respects. (See Hyacinth and Auricula, in the catalogue.)

6121. A parterre of annuals, as the different sorts generally come into flower about the same time, may either be arranged according to their species and heights, or dig some sorts, as of larkspur, chrysanthemum, lupin, &c., each species with its varieties may be sown in groups or beds, by itself; and the general principle by which to determine the sorts which are to join each other, may either be color and height, or natural character. If the latter, then the table exhibiting the genera, arranged according to the Jussieian classification (320), will be found a convenient guide.

6122. An American garden combines shrubs and even low trees. These may be arranged in the mixed method, according to color, height, and time of flowering, the trees and shrubs alone, and the plants alone, or both combined; but the most suitable and permanent arrangement is to keep the higher shrubs farther from the walk or side from which the group or border is to be chiefly viewed. This arrangement has an excellent effect in an American shrubbery, where the low species of heaths and other bog under-shrubs which are introduced, supply the place of herbaceous plants.

6123. A garden exclusively devoted to bulbous-rooted flowers, admits of being very perfectly arranged after the natural method. No orders run into other so naturally as, and none present a more harmonious assemblage both of foliage and flowers than, the Phanerogames. (589.) The planting of such a garden would involve the necessity of producing and selecting, in consequence, taking care to keep the taller bulbs, as lilium, fritillaria, &c. in the interior of the groups or beds.

6124. Gardens of spring, summer, or autumn flowers may be planted on any of the principles that have been mentioned.

6125. The changeable flower-garden. The essential principle of this garden consists in the power of changing its productions at pleasure, so that whenever any plant, or group of plants, begin to decay, they can be removed and their places supplied by others coming into bloom. To admit of this a large reserve-nursery is necessary, to which the plants must be kept in pots, for want of space. The Chinese, Sir W. Chambers informs us (Disert on Orient. Gard. 96.), excels in this mode of gardening; and we have been informed by a traveller who has resided some time at Canton, that he has known a mandarin (or noble) have the whole furniture and style of his parterre changed in a single night. But to present not only a different description of flowers, shrubs, and dwarf trees, but a different arrangement of the beds and compartments. Something of the same kind is practised in the gardens of the Tulleries in Paris; in some of the Imperial gardens at Petersburg, and in the vice-royal gardens at Monza. Gardens of this description admit of a perfect arrangement, according to order, group, or according to the natural method. It is only with such resources that a flower-gardener can "paint his way," as Sir W. Chambers says the Chinese artists do, "not scattering their flowers indiscriminately about their borders, but disposing of them with great circumspection, along the skirts of the plantable way, or to follow any natural orders, to be introduced.

The fact that all of that are of a straggling growth, of harsh colors, and poor foliage, choosing only such as are of some duration, grow either large or in clusters, are of beautiful forms, well leaved, and of tints that harmonise with the greens that surround them. They avoid all sudden transitions, both with regard to the height of the flower-stems, the foliage growing from the same green to the other; by the use of carnation-poppies, and others of the boldest growth; and varying their tints, by easy gradations, from white, straw-color, purple, and incarnate, to the deepest blues, and most brilliant crimsons and scarlets. They frequently blend several roots together, which, leat as Helianthus, Leucanthemum, and Composite, in a circle, of complete diaphanous, larkspurs, and mallow of different colors, double poppies, lupins, primroses, pinks, and carnations; with many more of which the forms and colors accord with each other; and the same method they use with flowering shrubs, blending white, red, and variegated roses together, purple and white lilacs, yellow and white jessamine, all of various sorts, and as many others as they can with any propriety unite. By these mixtures they increase considerably the variety and beauty of their compositions. In their large plantations the flowers generally grow in the natural ground; but in flower-gardens, and all other parts that are highly kept, they are in pots, buried in the ground, which, as fast as the bloom goes off, are removed, and others are brought to supply their places; so that there is a constant succession for almost every month in the year; and the flowers are never seen but in the height of their beauty."

6126. The botanical flower-garden being intended to display something of the extent and variety of the vegetable kingdom, as well as its resemblances and differences, should obviously be arranged according to some system or method of study. In modern times, the choice is almost limited to the artificial system of Linnaeus, and the natural method of Jussieu; though Adanson has given above fifty-six different methods by which plants may be arranged. (Fam. des Plant.) The latter has much the best effect in a garden, and corresponds better with culture. The former, though most convenient for the young student, yet by bringing plants together that have few or no obvious relations, it destroys that harmony which is so gratifying in viewing natural families. Whatever method is adopted, the plants may either be placed in regular rows, or each order may be grouped apart, and surrounded by turf or gravel. For a private botanic garden, the mode of grouping on turf is much the most elegant, and it has this advantage, that as the species belonging to the group are increased, it can be enlarged by appropriating a part of the turf, and any group containing few species may be filled up with repetitions for effect. The groups may be of the most irregular outlines, and those which are to contain trees may be raised or lowered in surface, according as the species may be natives of hills or
valleys, and the trees and plants so dispersed as that the former shall not conceal the latter, nor present a compact lumpish appearance at the edges, or in the outline against the sky. Rock-work may be introduced in groups where there are many alpines to be grown; and bogs, ponds, and springs imitated in others destined for aquatics, &c. as far as consistent with botanical purposes. A gravel-walk may be so contrived as to form a tour of all the groups (fig. 553.), displaying them on both sides; in the centre, or in any fitting part of the scene, the botanic hot-houses may be placed; and the whole might be surrounded with a sloping phalanx of evergreen plants, shrubs, and trees. The plants in such a garden should generally be neatly, but inconspicuously named, or, at all events, numbered; but naming is greatly to be preferred, as saving trouble to the spectator, and more inviting to the novice desirous of knowledge. It is hardly necessary to observe that the above modes, or others that we have mentioned, of planting a flower-garden, are alike applicable to every form or style of laying out the garden or parterre, and that they do not interfere with any mode of enclosing or surrounding it, or of edging the walks.

6127. Decorations. It is usual to employ different objects of art as decorations to flower-gardens, and the practice is founded in reason, since the works of nature and of art lend force to each other by their contrast. We have, in a former part (1805. to 1846.), enumerated the principal garden-decorations. Those more especially applicable to the flower-garden are the fountain in various forms; the open and covered, or rustic seat (fig. 555.); the statue (fig. 554.) in all its varieties of them, bust, single figure and group, and in the various materials of stone, metal, or verdure; the arbor, and a variety of others. Even the apiary and aviary, or, at least, here and there a beehive, or a cage suspended
from a tree, will form very appropriate ornaments. Sometimes inoffensive birds, as the seagull, may be introduced to run at large; gold-fish are very appropriate in the aquarium; and an animal which affords great amusement by its cry and song in the flower-gardens of the south of Germany, the tree-frog (Rana arbores), would be an acquisition in this country. In some families there is a taste for minerals or antiquities; and here, besides larger specimens distributed in the garden, a building (fig. 556.) may be introduced, combining a mineral cabinet (a), an aviary (b), and the botanic hot-houses (c).

6128. Where the old French style (figs. 545, 550.) is imitated, a profusion of marble and vegetable sculptures, vestibule arcades, colonnades, arbors, &c. are in character; but in the more simple and modern forms (figs. 540, 541, 543.) a few stools, sofa-chairs, a pavilion-seat (fig. 538.), a sun-dial, fountain, some urns, and a few good statues, will, in most cases, be sufficient. In the distribution of even these few decorations much judgment is requisite to avoid exciting ridicule by falling into the rapid, the flippant, or some other species of deformity. (See Schimmelpenninck on Beauty, &c.)

6129. Time of planting herbaceous plants. This is, in general, autumn and spring; but any perennial plant may be safely removed after it has done flowering or produced seed. With respect to biennials and annuals, they may be planted at almost any season before they have begun to throw up flower-stems. Biennials, however, are generally sown early in autumn in the flower-garden nursery, and transplanted either late in the same season or early in the following spring, to where they are to flower. Annuals are commonly sown in spring, where they are finally to remain. The culture of herbaceous flowers of the more valued sorts is exceedingly varied, and will be found under each species or class in the Flower-garden Catalogue. For the preparation of the soil and the manner of performing the operation, see these articles in (Chap. IV.) Planting the Shrubbery.

### Chap. III.

#### Of Forming the Shrubbery.

6130. By a shrubbery, or shrub-garden, we understand a scene for the display of shrubs valued for their beauty or fragrance, combining such trees as are considered chiefly ornamental, and some herbaceous flowers. The form or plan of the modern shrubbery is generally a winding border, or strip of irregular width, accompanied by a walk, near to which it commences with the herbaceous plants and lowest shrubs, and as it falls back, the shrubs rise in gradation and terminate in the ornamental trees, also similarly graduated. Sometimes a border of shrubbery accompanies the walk on both sides; at other times only on one side, while the other side is, in some cases, a border for culinary vegetables surrounding the kitchen-garden, but most generally it is an accompanying breadth of turf, varied by occasional groups of trees and plants, or decorations, and with the border, forms what is called pleasure-ground.

6131. The sort of shrubbery formed under the geometrical style of gardening (fig. 557.) was more compact; it was called a bosque, thicket or wood, and contained various compartments of turf or gravel branching from the walks, and very generally a labyrinth. The species of shrubs in those times being very limited, the object was more walks for recreation, shelter, shade, and verdure, than a display of flowering shrubs. What was wanting in natural beauty and variety, however, was made up by the art of the gardener in cutting such trees and shrubs as he had, into curious shapes. Shrubberies are often made for the sake of obtaining an agreeable walk to some particular place or scene, as the kitchen-garden, farm, wood, &c.; and sometimes in order to lead the spectator to different points, where views or distant prospects may be obtained. The most desirable shrubbery is one where both these objects are combined; and the least so, where the walk leads to no particular object, is shut up on both sides, and has no beauties to depend on but those of the shrubs. Hence Sir W. Chambers complains of walks en cul de sac, and Knight of "the shrubbery's insipid scenes," &c. (Tr. on Country Res. i. 352.) The shrubbery, however, judiciously laid out and planted, will always be a scene of considerable beauty and use about a country-seat. It is one of the principal resources for a home-walk for exercise; and as Repton has observed, a tolerable walk, even round one's own field, is more interesting than a better one where we have no interest. "We are greatly indebted to shrubbery," Nichols observes, "for much of the pleasure and delight we enjoy in our gardens. Though they produce no eatable fruits, nor afford us any sort of nourishment, yet they are particularly conducive to our comfort. In winter, they shelter us in our walks; in summer, they shade us from the sun. They afford a great variety of flowers, a varied foliage, and are standard ornaments that give us no great trouble. They are particularly useful in the character of screens, whether against the weather, or to hide disagreeable objects, in which case they may be planted nearer to the house than forest-trees. When planted in masses at a distance, they become agreeable objects, and often improve the scenery of a place. The shrubbery is of necessity as well a screen, in which case it gives the highest satisfaction. When formed for the purposes of shutting out the offices or the kitchen-garden from the view of the house; for sheltering the latter or the garden, or for connecting the house with the garden and the orchard, the shrubbery becomes useful and interesting."

6132. In respect to situation, it is essential that the shrubbery should commence either
immediately at the house, or be joined to it by the flower-garden; a secondary requisite is, that however far, or in whatever direction it be continued, the walk be so contrived as to prevent the necessity of going to and returning from the principal points to which it leads over the same ground: but as this is a matter which must be arranged in the general disposition or laying out of the residence, it need not be here entered on.

6133. The extent of the modern shrubbery must depend more on the extent of that place of which it is a part than on any other principle, and it is, or ought to be, so blended with the flower-garden lawn, as scarcely to admit of its quantity being estimated apart. Where the proportion of pleasure-ground, which may be judiciously apportioned to a residence, depends so much on the ground’s surface, and on the character or style of the whole seat, nothing definite can be laid down in the way of rules. The walks in the pleasure-ground should generally exceed a mile or two for the sake of recreation; but what proportion of these should be in open lawn, and what in flower-garden, or along the margin of a shrubbery, is too vague a question to receive any useful answer. Local circumstances and the character to be created must determine every thing. It may be mentioned as a characteristic distinction between the ancient and modern shrubbery, that the former was of limited extent, compact form, situated near the house, and that the length of walk was made up by repetition of parallel and cross walks. The whole of these had little distant prospect, and were generally more sheltered and shaded than is suitable for our climate; whereas, in the modern shrubbery, the length is made up by stretching out the walk to a distance; and air and ventilation, as well as views and prospects, are obtained by its being planted chiefly on one side. Such shelter and shade as is deemed requisite for the walk is obtained by the introduction of scattered trees along its open margin.

6134. Soil. “Shrubs, in general,” Nicol observes, “thrive very well in ordinary garden-land, and better in light than in heavy soils. Most shrubs, likewise, do well in ground a foot in depth; but it is always advisable to trench to the full depth of the soil, previous to planting, if that were even two feet. Manure is seldom bestowed on shrubs, and if the soil be not far below mediocrity, it is seldom necessary, provided the ground be otherwise well prepared, and be meliorated by trenching or diggin. In the case of planting screens, where it is desirable to have them effectual as soon as possible, or in planting favorite shrubs in particular situations, every justice should be done to the soil in preparing and enriching it, either with manure or by the addition of fresh earth. Those who are curious in collections of certain shrubs, prepare or choose certain soils for them. Evergreens, for the most part, thrive well in loam of a middling texture; but some kinds do better in mossy humid earth, as the azalea and rhododendron. Deciduous shrubs, in general, thrive well in light loams or sandy soils; but certain kinds flower better in rich mellow earth, as the mss-rose and the robinia.”

6135. Walks. “The conducting of walks,” Nicol says, “through the shrubbery, is a matter both of conveniency and of taste: of conveniency, when the shrubbery is merely a passage from one place to another, or a narrow screen to the garden. In the former case, the walk should be simple and direct: in the latter case it may be circuitous; and if there be any variety in the ground, it ought to lead to particular points of view. The walks, however, should seldom cross one another; they should rather take off at oblique angles; nor should one run parallel to another within view. It is proper to show off the shrubs, but too many walks perplex. Their breadths may be various. If short, they should be narrow; if long, and if a considerable reach be caught at once, they should be broad. A medium may be taken at five feet, the extremes being three and eight. They may be of turf or of gravel; but the latter is always most wholesome, and most agreeable in winter.” In the ancient style, where the shrubbery, or umbrageous scene (fig. 557. a.), often enclosed the flower-garden (b), both being situated in front of the house (c), the walks (d) were laid out in arbitrary geometrical shapes, crowded and numerous, to afford sufficient space for recreation, and varied by niches (e), boudoirs (f), salons (g), and other open parts to give variety.

6136. Fence. Local circumstances must, in almost every case, determine the sort of exterior or boundary fence most proper for the shrubbery or pleasure-ground; the interior, or that on the open side, should, in almost every case, be one of the inconspicuous kind; either light iron-railings, moveable hurdles of wood or iron, or the sunk-fence. Where the shrubbery is not a boundary plantation, a light fence may include it on both sides; but so much depends on locality and other arrangements, that the subject cannot be profitably discussed separately from that of laying out the entire residence. Under the geometric style, the business of fencing the shrubbery or woody scene, was very simple, the whole being generally surrounded by a high wall. “Fences of all kinds,” Abercrombie observes, “are rather necessary and useful as instruments of shelter and security than to be chosen as materials of ornament. Whether the view terminates on the fence, or is directed beyond it, the effect on the scene, at best, is negative: thus, a fence is sometimes made higher than its proper use requires, merely to shut out something more unsightly; and, in judiciously employing that capital invention, the sunk-fence or
ha-ha, the advantage, though great, is purely negative; some prospect worth retaining at considerable cost is not obstructed."

6137. Reserve-ground for the shrubbery. A plot of ground should be set apart for the propagation and culture of the more tender shrubs, to supply deaths or accidents in the front of the shrub-border. This reserve-nursery will be most conveniently situated when joined to that of the flower-garden; but it may also be taken from the interior of any wide part of the plantation where it will not be seen. Here roses, mezereons, American shrubs, honeynuckles, and a variety of the more ornamental and tender sorts should always be in readiness, partly in pots and partly in nursery lines, to remove to the principal scene, either to add to its usual beauty, or to compensate for accidental defects. To the same ground may be added a space for accumulating leaves, spray, and other refuse of the shrubbery, to ferment and produce manure for the nursery in the same way as is done in the compost-grounds of the kitchen and flower garden.

Chap. IV.

Of Planting the Shrubbery.

6138. On planting the shrubbery the same general remarks, submitted as introductory to planting the flower-garden, are applicable; and shrubs may be arranged in as many different manners as flowers. Trees, however, are permanent and conspicuous objects, and consequently produce an effect during winter, when the greater number of herbaceous plants are scarcely visible. This is more especially the case with that class called evergreens, which, according as they are employed or omitted, produce the greatest difference in the winter aspect of the shrubbery. We shall here describe four leading modes for the arrangement of the shrubbery, distinguishing them by the names of the mingled or common, the select or grouped manner, and the systematic or methodical style of planting. Before proceeding farther it is requisite to observe, that the proportion of evergreen trees to deciduous trees in cultivation in this country, is as 1 to 12; of evergreen shrubs to deciduous shrubs, exclusive of climbers and creepers but including roses, as 4 to 8; that the time of the flowering of trees and shrubs is from March to August inclusive, and that the colors of the flowers are the same as in herbaceous plants. These data will serve as guides for the selection of species and varieties for the different modes of arrangement, but more especially for the mingled manner.

6139. To dispose shrubs and trees in the mingled manner, proceed as under. The width of the space to be covered with trees, shrubs, and flowers being given, first mark it out in rows lengthways. The first
row may be two feet from the margin of the turf or the edge of the walk; the second, three feet from the first; the third, four feet from the second; and so on to the back of the plantation. Suppose the width to admit of ten rows (fig. 558. a to k), then the six rows next the walk will occupy a space of twenty-seven feet, which may be devoted to shrubs, and the remaining three rows will occupy a space of thirty-seven feet, and may be planted with trees. Then beginning with the first row, which is destined for the lowest class of shrubs, arrange them according to the times of their flowering, which will, as in arranging herbaceous plants, be most conveniently done at six times: viz. 1, March; 2, April, &c. to 6, August; and they will stand as in the flower-border in the order of 1, 6, 5, 4, 3, 2, and with the colors in the same manner (a). The second row (b) is to be arranged in the same manner; and as trees, though nearly of the same size when planted, yet attain finally very different degrees of bulk, provision must be made for the plants in each row to expand year after year, till they attain their full growth. This we propose to do by planting two plants of a sort in the second row (b), three in the third, and so on (as indicated in the figure), till in the last or tenth row (k), there will be ten plants of a sort in a line together. It is to be observed, that a deciduous and an evergreen sort (marked d, e, in the figure) are to be planted alternately, in order to ensure an equal mixture in respect to verdure; and that the colors (denoted by r, w, b, y, in the figure) are mixed as in the mingled border, to ensure a general display of mixed blossoms. The second or third year such of the plants are to be thinned out as crowd the others, reserving, however, as final plants, one of each sort, (say E for the evergreens, and D for the deciduous sorts), so placed in respect to the plants in the other rows, as that the whole, when finally thinned out, may stand in quinuncx. The largest trees will then occupy about 100 square feet each; and each of the shrubs in the front row about a square yard: there will be the same number of deciduous plants as evergreens; some shrubs of all the four colors in blow throughout the whole season, and a verdant aspect in summer as well as winter.
6140. The distance between the rows of trees (ten feet) may in some cases be an objection, for a year or two at first; but this, we consider, will be more than counterbalanced by the opportunity afforded of cultivating the ground between them, and by the air and light admitted to their side shots, which will the sooner fit them for producing blossoms. All formality of appearance will soon be done away by the irregular growth of the plants, and by the thinnings which must take place in, at the latest, three years after planting. If any, however, object to the appearance of rows, they may be obliterated, by introducing some plants in the intervals of the same sort as those in the lines adjoining; but in doing this, care must be taken not to lose sight of the shrub or tree which is finally to remain, as it is of importance to this plan, (which is not natural or picturesque planting), that the regular disposition of the whole be preserved, as well with a view to the gradation of height as to the mixture of color in the flower, and of permanent and deciduous foliage. The herbaceous plants only remain to be added. These are to be inserted one row in front of the first row of shrubs (o), and three or more rows \((p, q, r, s)\) in the intervening spaces between the next rows. The plants are to form a quincunx with the shrubs; and the same arrangement as to height, color, and time of flowering, adopted as in the mingled border. Such a shrubbery may be commenced with \((2 \times 6)\) twelve sorts of evergreen, and the same number of deciduous trees; with \((6 \times 6)\) thirty-six sorts of shrubs, half the number deciduous, and half evergreen; and with \((3 \times 6)\) thirty sorts of herbaceous plants. It may then be continued either by repeating the pattern with the same sorts, or by other sorts; or principally by the same sorts, with some others occasionally. If a show of flowers is valued, the sorts employed must be comparatively few, as the flowers of the greater number of trees and shrubs are of dull colors, or little conspicuous. The evergreen trees, in a popular sense, can hardly be said to have any flower; but still a number of them must be introduced in the back rows, to blend with horse-chestnuts, limes, acacias, wild cherries, wild pears, &c.

6141. The select or grouped manner of planting a shrubbery (fig. 559,) is analogous to the select manner of planting a flower-garden. Here one genus, species, or even variety, is planted by itself in considerable numbers, so as to produce a powerful effect. Thus the pine tribe, as trees, may be alone planted in one part of the shrubbery, and the holly, in its numerous varieties, as shrubs. After an extent of several yards, or hundreds of yards, have been occupied with these two genera, a third and fourth, say the evergreen fir tribe and the yew, may succeed, being gradually blended with them, and so on. A similar grouping is observed in the herbaceous plants inserted in the front of the plantation; and the arrangement of the whole as to height, is the same as in the mingled shrubbery.

6142. The chief difficulty in this manner of planting is so to select the sorts that are to succeed each other, so to blend one group or kind with those adjoining, and at the same time maintaining the requisite gradation from the front to the back of the plantation, as to preserve to the spectator in walking along, the appearance of a whole. When this is successfully accomplished, and on a large scale, no kind of shrubbery can be more beautiful in summer; but in winter it will present parts wholly without evergreens, and it will only be rich in flowers in some parts; as for example, where the roses, spirea, mespilææ, &c. are introduced. By proper contrivance, however, the evergreens, the showy flowering deciduous kinds, and the less showy deciduous sorts may form three divisions, and the two former can be kept nearest the mansion. The best guides as to the sorts proper to adjourn each other, are the general form and mode of growth; and next, the color and foliage. In these particulars the transition should always be gradual. Thus, among the trees, the pines, cedars, firs, and yew, form a regular gradation, and the shrubs which may be placed near them are the arbor vitae, juniper, whin, &c. To place groups of weeping-willow or elm adjoining the pines, and to select roses and lilacs as shrubs, would produce a harsh and incongruous effect. There is obviously much less natural affinity between herbaceous plants and shrubs than between shrubs and trees; but the groups of the herbaceous plants must harmonise among themselves on the same general principles as the trees; thus pink-looking plants (carpophylleæ), should not be succeeded by coarse broad-leaved sorts (boragineæ), but rather by more delicate kinds, as grasses or primula, &c. There may sometimes also be a certain species of relation between the herbaceous plants and shrubs; thus the bulbous-rooted kinds, and small early flowers, as violets, primula, will be more fitly planted among evergreens and early-flowering deciduous shrubs than among late deciduous kinds.
6143. Various other modes of select-planting shrubberies may be adopted; such as collecting together all such shrubs, trees, and flowers as flower at the same time, or have the same color of flower, or foliage, or the same odors, or the same general shape, or the same natural habitation, as of marshes, mountains, &c., or the same country, as America, Switzerland, Sweden, &c. But the intelligent gardener who has attended to what has been already advanced, can hardly require farther instructions to form such plantations. We would suggest, as worth trial, where there was ample space, the mode of arranging by odors; the ancients are said to have paid particular attention to this in mixing their trees. (Falconer, &c. and see 57.) Every one must have experienced a difference in this respect between walking in a pine-forest, a plantation of balsam-poppars, a birch-copse, and beside sweet-briar and juniper hedges. An arrangement of this kind, depending on the smell of the buds and leaves, rather than of the flower, would have its effect the greater part of the year, especially after showers.

6144. Systematic or methodical planting in shrubberies consists, as in flower-planting, in adopting the Linnaean or Jussieuenean arrangement as a foundation, and combining at the same time a due attention to gradation of heights. This mode, executed on a grand scale, would unquestionably be the most interesting of all, even to general observers; but on a small scale it could not be so universally pleasing as the mingled manner, or the mode by select grouping. The uninstructed mind might be surprised and puzzled by such an assemblage; but not perceiving the relations which constitute its excellence, they would be less pleased than by a profusion of ordinary beauties; by a great show of gay flowers and foliage. Dr. Darwin is said to have blended picturesque beauty with scientific arrangement in a dingle at Litchfield, where he disposed of a large collection of trees and plants in the Linnaean manner. The same thing may be attempted on any description of surface, and with any form of ground-plan, provided turf be introduced, and care be taken to elongate the groups containing trees in such a way as to preserve a sufficient degree of woodiness throughout, both for shelter, shade, and picturesque effect.

In this way we have arranged a spot (fig. 560.) of little more than an acre and a half, so as to ordinary observers, to be nothing more than a house surrounded by pleasure-ground, but to the botanist and painter, to be a scientific and picturesque scene. This spot combines a villa and offices (e), a kitchen-garden (b), reserve-garden and melonground (c), botanic ground for herbaceous plants (d), rock-work (e), rosarium (f), aquarium (g), American ground (k); besides a variety of other subordinate scenes, a scattered orchard (i), and the shrubbery (k), arranged in irregular, elongated groups on lawn, in the manner mentioned. But much the most interesting mode of arrangement would be that of Jussieu, by which a small villa of two or three acres might be raised, as far as gardening is concerned, to the ne plus ultra of interest and beauty. To aid in the formation of such scenes the tables (588, 589.) exhibiting the genera contained in each Linnaean or Jussieuenean order, and also the number of species distributed according to their places in the garden, will be found of the greatest use.

6145. Chinese arrangement. It is only since the great influx of trees and shrubs from America, during the latter half of the last century, that the idea of arranging shrubs found a place in the writings on gardening. Sir W. Chambers seems to have been the first who suggested it in his account (whether correct or not, is of little consequence to our present purpose), of the practice of the Chinese gardeners. The Chinese, he says,
in their plantations, do not, as is the practice of some European gardeners, plant indiscriminately every thing that comes in their way; nor do they ignorantly imagine, that the whole perfection of plantations consists in the variety of the trees and shrubs of which they are composed: on the contrary, their practice is guided by many rules founded on reason and long observation, from which they seldom or never deviate. Many trees, shrubs, and flowers, they say, thrive best in low moist situations; many on hills and mountains: some require a rich soil; but others will grow on clay, in sand, or even upon rocks; and in the water: to some a sunny exposition is necessary; but for others, the shade is preferable. There are plants which thrive best in exposed situations; but, in general, shelter is requisite. The skilful gardener, to whom study and experience have taught those qualities, carefully attends to them in his operations; knowing that thereon depend the health and growth of his plants; and, consequently, the beauty of his plantations.

6146. The perfection of trees for ornamental gardening consists in their size, in the beauty and variety of their forms, the color and smoothness of their bark, the quantity, shape, and rich verdure of their foliage, with its early appearance in the spring, and long duration, and also in the formation, beauty, and hardness to endure the extremities of heat, cold, drought, or moisture; in their making no litter, during the spring or summer, by the fall of the blossom; and in the strength of their branches, to resist, unhurt, the violence of tempests.

6147. The perfection of shrubs consists, in the most of the above-mentioned particulars, but also in the beauty, durability, or long succession of their blossom; and in their fair appearance before the bloom, and after it is gone. We are sensible, say they, that no plant is possessed of all good qualities; but choose such as have the fewest faults; and avoid all the exotics that vegetate with difficulty in our climate; for they may be rare, they cannot be beautiful, and therefore not durable in a sickly state.

6148. The excessive variety of which some European gardeners are so fond in their plantations, the Chinese artists blame; observing, that a great diversity of colors, foliage, and direction of branches, must create confusion, and destroy all the magnificence which either some single tree, or its branches, can otherwise yield. The Chinese, on the other hand, say, that not only the trees, but also the plants and flowers, must be suitable to their situations. They admit, however, of a moderate variety; but are by no means proiniscuous in the choice of their plants; attending, with great care, to the color, form, and foliage of each; and only mixing together such as are suitable for the same place. They endeavour to make each plant the proper and only proper for the situation in which it is; and if a bushy, compact growth is required, for the gravel walks; others, only fit to be employed singly: and others, equally adapted to both these situations. The mountain cedar, the spice and silver firs and all others whose branches have a horizontal direction, they hold improper for thickets: because they increase, in height, as much as in breadth; yet they do not disagreeably upon the plantations, if used in detached and isolated; as the arbor vitae and the sumach, or any of such heterogenous sorts; but, on the contrary, they assemblé in their large woods, the oak, the elm, the beech, the tulpeo, the sycamore, maple, and plane, the chestnut, the walnut, the arbele, and the lime, and all those whose luxuriant foliage hides the direction of their branches; and growing in globular masses, are arranged to be set well together; forming, by the harmonious combination of their tints, one grand group of rich verdure.

6149. In their smaller plantations, they employ trees of a smaller growth, but of the same concordant sorts; bordering them with Persian lilacs, guelder-roses, syringas, cornollas of various sorts, flowering raspberries, yew, jessamine, hypericum, the spirea freë, altheas, roses, and other flowering shrubs peculiar to China; and wherever the ground is bare, they cover it with white, blue, purple, and variegated periwinkle, the convolvulus minor, dwarf stocks, violets, primroses, and different kinds of creeping flowers; and with strawberries, tutsan, and privet, which climbs up and covers the stems of general, there ought to be planted; these horizontal-branched trees with the express, the oriental arbor vitae, the bamboo, or other upright ones; nor with the larch, the weeping willow, the birch, the laburnum, or any of a pendent nature; observing, that the intersection of their branches forms a very un picturesque kind of network; neither do they employ together the catalpa and the mimosa, as the French do, of whom they never mix these horizontal-branched trees with the express, the oriental arbor vitae, the bamboo, or other upright ones; nor with the larch, the weeping willow, the birch, the laburnum, or any of a pendent nature; observing, that the intersection of their branches forms a very un picturesque kind of network; neither do they employ together the catalpa and the mimosa, as the French do, of whom they never mix.

6150. British practice. Soon after Sir William Chambers's work appeared that of Wheatley, which contains some excellent remarks on the subject (Obs. on Gard. sect.xii. xiii. xiv.), and subsequently Uvedale Price's excellent Essays on the Picturesque, vol. i. In 1804 we endeavored to enforce the principle, not only in planting trees, but in arranging herbaceous plants, and the plants in botanic hot-houses. (Obs. on Planting and Landscape Gard. 8vo.) All these efforts were at first treated as visionary by Marshal, Nicol, and other planters and gardeners. But Nicol, in the last editions of his works, allows there may be some merit in grouping; and Sang, his editor, highly approves of following nature in the arrangement of their trees. (Plantar. Kalend.)

6151. Nicol says, "the proper disposition of shrubs, where many are to be planted, is a matter of considerable importance in the future appearance of the whole, and those whether they be mixed, or be grouped; that is so, that whether deciduous or evergreen shrubs be indiscriminately mixed, as is often done, or the evergreens be planted distinctly by themselves. The arrangement of shrubs is a matter, no doubt, very much of fancy. In some parts they may be mixed; in others grouped; but, in general, there ought to be planted; in the whole may thrive, and be cheerful in winter. Generally speaking, however, the method of mixing all kinds of shrubs indiscriminately, prevails too much in modern shrubbery. Much more character and distinctness may be given, by judiciously grouping them, than by following the common methods of planting."

6152. Arboreto, or rather his posthumous editor, seems undecided in his observations on this subject. In one place he says, "in the distribution of plants over grounds dedicated to elegance, there are two rival systems, each of which has its practical followers and theoretical vindicators. One prefers the indiscriminate mixing of all sorts; the other deliberates the propriety of each, which have some marks of affinity. It is still a question, which order of planting is countenanced by the practice of nature in self-sown vegetables; and which will confer on a garden the stronger claims to character and beauty." He elsewhere observes, that "the different natures of herbaceous plants, shrubs, and trees stand in the way of every attempt to govern their distribution or assemblage by a common principle." In planting trees, however, he subjoins, "the principle of unity may be consulted, without losing sight of the advantage of variety," etc. (Pr. Gard. 477.)
6154. Fruit-trees in shrubberies. "In shrubberies of considerable extent, fruit-trees may be interspersed at fifteen or twenty yards' distance, by which means a good deal of fruit may be obtained, and very much beauty added to the shrubbery. In spring the blossoms of apples, cherries, and pears are beautiful; in autumn their fruits and the foliage of cherries in particular, give a lustre and variety that highly brightens the appearance of other plants, especially of evergreens." (Villa Gard. Direct. 16.) This mode, Sir W. Chambers tells us, is practised by the Chinese when the patron is poor; that is, their shrubbery is composed of fruit-trees, and shrubs, and forms a sort of ornamental orchard. This we consider an advisable mode for an economical farm-residence; but the general introduction of fruit-trees, in even mingled shrubberies, unless of the species in their wild state, as crabs, wildings of pears, cherries, quinces, raspberries, &c. we consider as likely to destroy the character of the scene. It must be recollected too, that grafted trees, especially the apple and cherry, seldom grow so freely and produce such vigorous and natural-like heads as plants raised from seed; they are, therefore, soon overtopped by the others, or where they are placed among trees that do not grow higher than themselves, they seldom fail of producing deformed stunted heads.

6155. Forsyth, Abercrombie, and others, recommend their introduction, as it appears to us, without due regard to any other object than the fruit they will produce, and the fugacious beauty of their blossoms; but their unaccommodating form, and their influence as to character in ornamental plantations, we consider as sufficient arguments against the practice in general cases.

6156. Decorations in shrubberies. Those of the shrubbery should in general be of a more useful and imposing character than such as are adopted in the flower-garden. The green-house and aviary are sometimes introduced, but not, as we think, with propriety, owing to the unsuitableness of the scene for the requisite culture and attention. Open and covered seats are necessary, or, at least, useful decorations, and may occur here and there in the course of the walk, in various styles of decoration, from the rough bench to the rustic hut (fig. 561.) and Grecian temple. (fig. 562.) Great care, however, must be taken not to crowd these nor any other species of decorations. Buildings being more conspicuous than either statues, urns, or inscriptions, require to be introduced more sparingly, and with greater caution. In garden or ornamented scenery they should seldom obtrude themselves by their magnitude or glaring color; and rarely be erected but for some obvious purpose of utility.

6157. Covered seats and shelters are introduced of many forms, and under a great variety of names, such as root-houses, heath-houses, moss-houses, huts, shelters, (fig. 563.) bowers, caverns, caves, grottoes, temples, mosques, &c. besides plain covered seats either of wood or stone. The imitation of temples or mosques, as they must be on a small scale, is generally quite ridiculous. The propriety of introducing the others depends entirely upon the character of the scene. Light bowers formed of lattice-work, and covered with climbers, are in general most suitable to parterres; plain covered seats suit the general walks of the shrubbery. Most of the others may be introduced in romantic, singular, wild, or melancholy places.
6158. Statues, whether of classical or geographical interest (figs. 564. and 565.), urns, inscriptions, busts, monuments, &c. are materials which should be introduced with caution. None of the others require so much taste and judgment to manage them with propriety. The introduction of statues, except among works of the most artificial kind, such as fine architecture, is seldom or never allowable; for when they obtrude themselves among natural beauties, they always disturb the train of ideas which ought to be excited in the mind, and generally counteract the character of the scenery. In the same way, busts, urns, monuments, &c. in flower-gardens, are most generally misplaced. The obvious intention of these appendages is to recall to mind the virtues, qualities, or actions of those for whom they were erected: now this requires time, seclusion, and undisturbed attention, which must either render all the flowers and other decorations of the ornamental garden of no effect; or, if they have effect, it can only be to interrupt the train of ideas excited by the other. As the garden, and the productions of nature, are what are intended to interest the spectator, it is plain that the others should not be introduced. This reasoning, while on the one hand it shows the absurdity of such a practice, on the other, directs that urns, monuments, &c. should only be placed in solitary unfrequented places, where the mind is naturally led to contemplate, and where the remembrance of the virtues of great men, or the worth of relations now no more, afford proper subjects for contemplation. But even in places apparently solitary, or secluded, these have been introduced in so affected or improper a manner, as to furnish reason for the greatest caution in future. (Tr. on Country Res.)

6159. A cottage, when the walk of a shrubbery is of great extent, may sometimes be advantageously introduced in a distant part of it, with an occupant, for the purpose of keeping one apartment in order as a place of repose. Such a cottage (fig. 566.) may be designed in any style, according to the taste of the owner, and may serve a variety of useful purposes. In the gardens laid out under the direction of the Queen of Geo. III. at Frogmore, and in the walks of what are called the slopes at Windsor, are some good examples of rustic seats, and ornamented shrubbery cottages.

6160. On the subject of planting both flower-gardens and shrubbery we may remark, with the author of the Florist's Manual, that it is considered in much too unimportant a light, both by gardeners and their employers. The business is almost everywhere performed at random, instead of being conducted with a specific object in view. To remedy this evil, gardeners should first make a correct plan of the border, parterre, or plot, of whatever kind it may be, that is to be planted; and then having determined the mode of arrangement most proper, and selected the names of plants to effect it, from the proper catalogues, the situation of every plant and its name should be determined on the plan. This done, all these points should be correctly transferred to the ground, and a pin or stake inserted at each, numbered in correspondence with a list of the sorts. The plants being procured, should then be distributed and planted according to these stakes and numbers; and the stakes should be allowed to remain for a year or two, to make certain as to the sort to be replaced there, in the case of death or accident. If ever this branch of gardening should attain a high degree of perfection in Britain, it will probably be deemed as necessary to call in a professor to direct the arrangement of flowers and shrubs in parterres and shrubberies, as it is now to require his aid in arranging the ground-plan.
Chap. V.

Of the Hot-houses used in Ornamental Horticulture.

6161. The hot-houses of floriculture are the frame, glass case, green-house, orangery, conservatory, dry-stove, the bark or moist stove, in the flower-garden, or pleasure-ground; and the pit and hot-bed in the reserve-garden. In the construction of all of these the great object is, or ought to be, the admission of light and the power of applying artificial heat with the least labor and expense. In culinary forcing-houses, it is requisite to attend to the angle of the glass roof, so as to obtain most of the sun's influence at the time the fruit within is to be ripened; but in the hot-houses of the flower-garden or pleasure-ground, the construction ought to be such as to admit as much light as possible in winter; for then in the stoves a heat is kept up by art, which is not to be found in any natural climate connected with so little light as is then afforded in our latitude. Hence, as a general principle it may be affirmed, that the roofs of all plant or botanical hot-houses should be steep rather than flat, and, perhaps, the angle of 45° may be fixed on as the fittest average. It was adopted by Miller, both in culinary and ornamental hot-houses, and is fitter for general purposes than any other.

6162. The frame used in ornamental horticulture is generally of the same form as those of the kitchen-garden. For alpine plants this form succeeds perfectly, but for frame-shrubs, the ends and front should be deeper than usual, and glazed half their depth, to admit the sun to the surface of the adjoining pots. Frames for the taller bulbous-rooted flowers, should either be glazed in front and at both ends, or if opaque in those parts, should be placed on a steep surface for the same general object. Frames of every description should have a gutter or spout in front, to carry off the rain-water which falls on the sashes.

6163. The glass case may be variously constructed from detached sashes; it is used to protect standard trees or shrubs, and sometimes to place against walls or espaliers. (see fig. 526.)

6164. The green-house may be designed in any form, and placed in almost any situation as far as respects aspect. Even a house looking due north, if glazed on three sides of the roof, will preserve plants in a healthy vigorous state. A detached green-house, even in the old style, may be rendered an agreeable object in a pleasure-ground, of which, as an example, we may refer to one (fig. 567,) erected by Todd, for

E. Liebenrood, Esq. near Reading; but the curvilinear principle applied to this class of structures, admits of every combination of form, and without militating against the admission of light and air. Though we are decidedly of opinion, however, that as iron roofs on the curvilinear principle become known, the clumsy shed-like wooden or mixed roofs now in use will be erected only in nursery and market-gardens; yet we are not to be understood as exclusively recommending our own plans, and we, therefore, describe that of Todd, whose book contains a number of examples, erected in different parts of the country, and in the best manner of the old style. "This house (fig. 567,) has a span roof, and the centre lights, which are balanced by weights, made in imitation of acorns, suspended from the ridge of the roof, are made to slide, to admit air from the roof. The front and ends are formed with folding casements, hung so as to be taken away at pleasure; and between each is a pilaster of treillage-work. A cast-iron column at each extremity of the upper part of the roof, is placed for the purpose of keeping it from spreading, as such roofs generally do, unless held together by a transverse tie, which has a less pleasant appearance than a column. A
single fire heats this house; the flue goes under the floor round the front and ends, rises and continues above the floor along the back wall, and terminates in a chimney in the centre. Over the stock-hole is placed a cistern, which is supplied from the roof, and occasionally from a pump adjoining, with water, which is conveyed into the green-house by a lead pipe." (Plans for Green-houses, &c. p. 11.)

6165. The most suitable description of green-house or conservatory for the flower-garden is that with span roof (fig. 568.), because such a house has no visible "hinder parts," back walls, stock-holes, or other points of ugliness, with which it is difficult to avoid associating all the shed, or lean-to forms of glazed buildings with back walls. Several elegant houses of this description have been erected by Messrs. Bailey. An example occurs in the Regent's Park, at the villa of W. H. Cooper, Esq.; another at Walthamstowe, in the grounds of P. Kendal, Esq.; and several more are mentioned in the table already given (1587.), or are in course of erection.

6166. In the interior of the green-house the principal object demanding attention is the stage, or platform for the plants. In a double-roofed house, surrounded by a path, the stage generally consists of shelves, rising from the path to the middle of the house (fig. 567. a and b); but in a house with a single roof (fig. 569.) it generally rises from the front part to the back, and in both cases the slope of the stage is generally the same or somewhat less than the slope of the roof. In the green-houses destined for very large or tall-growing plants, as camellias, and many of the New Holland plants, no stage is requisite; and in such as are destined for small plants, as heaths and geraniums, the first step of the stage, when there is a path between it and the front glass, should be raised at least two feet and a half high, and it may then be continued parallel to the roof. The object of this arrangement is to bring the plants near the glass, so as they may obtain the benefit of the light in a state as little decomposed as possible. Flues in green-houses are frequently carried above ground, which is inelegant and too much in the style of the common forcing-house. They may in almost every case be conducted under the path or stage, and by keeping them detached so as air may circulate round them, as much heat will be given out as by the common mode. In general one fire will be sufficient to warm from 4000 to 5000 cubic feet of air, of the temperature requisite for green-house plants. (see 1662.) In some cases trellis-rods are placed at regular distances under the roofs of green-houses, for the purpose of training vines; but this practice is incompatible with a high degree of culture and beauty in the green-house plants, on account of the light it excludes; besides, it interferes with character. If any creepers or climbers are to be trained under the roofs, they should be of the ornamental kind; but it is generally best to train them to upright rods at the back part of the house, or rods forming intersecting arches over the back paths, or against the back wall; for by either of these modes they exclude less light, better display their foliage and flowers, and less recall the idea of the forcing-house.

6167. Abercrombie and Nicoll give descriptions of green-houses, such as they approve; the former is rather indefinite in his remarks; but the latter has given the best instructions that have yet appeared, as far as respects the good forms and mode of treating and ventilating.

6168. According to Abercrombie, "The green-house may be made a very ornamental object as a structure. The front of the building should stand directly to the south, and the ends have an open aspect to the east and west. The extent of the green-house may vary, according to the largeness of the collection to be cultivated: when most contracted it should considerably exceed the breadth and height, in order to have handsome proportions. As to the breadth, were it more than twenty feet, those plants most remote from the windows would be troublesome to manage, as they must stand on very high stages to be reached by the sun; between twelve and twenty feet will be found the most commodious latitude. The front, including a low parapet wall and a row of windows, or upright glasses, may be eight or ten feet high, measured from the floor to the top line. It will be proper to lay the floor at least twelve inches above the level of the ground, and in damp situations two feet. The back is the only part at which an entire wall should be carried up to the roof; the precise height of this wall depends upon that of the glass front and the breadth of the house; the proportions of these three must be so accommodated as to give the proper slope to the roof."

6169. According to Nicoll, "In the construction of green-houses, fancy may be indulged, and a greater scope may be allowed to taste, than in the construction of forcing-houses. These are generally confined to one object, the production of certain fruits in perfection; which renders the observance of forms and distances in the construction of them less necessary than in that of the green-house, where a variety of plants of different habits are to be cultivated. Nevertheless, in order that these plants may generally thrive, there are certain rules to be observed, and errors to be guarded against, which I shall briefly point out. Green-houses with upright fronts, and with perpendicular lights only, whether the columns that separate them be of wood or of masonry, are the most objectionable; as the plants in such are always drawn up weak, and are distorted by continually stretching towards the light. Neither do they enjoy the genial effects of the sun, except in the winter months, when his rays, though feeble, strike horizontally on the window. They should be let in for a few hours in the middle of the day, and the lower lights, on the low plants, and those placed most forward. If such houses be very wide, they are the most objectionable on that account; as, in that case, the plants placed near to the back of the stage are never visited by the rays of the sun, and enjoy but little light to what they may require. But such green-houses may be, and indeed have been, much improved, by taking off their leader or slated roofs, and by substituting roofs consisting of wooden framing and glass, for the admission of sunshine and perpendicular light. But still they are so far defective, as that, by their great height, the plants are much more drawn than they ought to be, or would be, in a
lower and better-constructed house. Houses that are open on the front only, although they have sloping lights on the roof, are next to be objected to; as the plants in such are necessarily more drawn and distorted than if the ends were also glazed. If such be not placed among other buildings, so as that they cannot be altered, they might be very much improved by pulling down the close ends, and by substituting glazed lights; which, if they be of a moderate height, would render them next best to such houses as are described below."

6170. A complete green-house, being quite detached from other buildings, should be glazed on all sides. "It may be a circular, oval, hexagonal, octagonal; or with two straight sides, and circular ends, which I think the best form of any; the next best, an octagon, whose sides are not equal, but with two opposite longer sides, and six shorter sides; three and three opposite, forming, as one might say, an oval angular; the ends being angular, instead of round. In either of these last-mentioned forms, the stages and plants may, at least in my mind, be more tastefully arranged, than in any other. Granting either of these cases, the house should be about thirty-six or forty feet long, eighteen or twenty feet wide, and ten, or at most twelve feet high, above a given level line for its floor. The parapet all round to be a foot or fifteen inches high, and the upright glasses placed on it, four, or four and a half feet at most. For it is of importance, for the sake of the finer kinds of plants, and in order to have all kinds grow bushy, and flower while young and small (in which state they are certainly most attractive and pleasing), to keep the roof-glasses as low as possible; just allowing sufficient head-room to the tallest person when walking in the alleys. The furnace and stock-hole may be placed at either end, or at either side, as may be most convenient; and they should be sunk under ground, and be concealed. The flue to be constructed, to run parallel to, and be separated from the parapet by a three-inch cavity; its surface being level with the top of the parapet, and being crib-trellised for heaths, Botany Bay, and other rare plants. A walk thirty or thirty-six inches broad, to be conducted all round next the flue, within which to be placed the stages for the more common, and the taller plants; being raised in the middle, and falling to either side and end; corresponding with the glasses, though of course not so steep. A row of columns should be placed in the centre, in order to support the ridge of the roof; to which climbing plants might be trained in various forms, and might be hung in festoons from column to column at top, or otherwise, as may be dictated by fancy. The front of the stage all round should be raised about eighteen or twenty inches above the walk, in order to raise the whole of the plants placed on it sufficiently near to the glass; thus forming the walk into a deep alley; the person walking in it having a narrow border of the finer and smaller plants on the one hand, and a bank of the more common and larger kinds on the other; than which, when the plants are healthy and thriving, few scenes can be more pleasing. The aspect of such a house should be towards the south; that is to say, it should stretch from east to west, or as nearly so as circumstances will permit. It may have an entrance on the south side, or one at either end, as shall be most convenient and suitable to its connection with the walks of the shrubbery or parterre in which it is placed. If a green-house must necessarily be attached to a wall or other building, it might be constructed very much as above; with this difference, having one of the ends, as it were, cut off; in which case, it should be placed with its circular end south, or towards that point, and the sides pointing east and west. This I should consider as the second best-constructed green-house, and in which, excepting in the above-described house, the plants would enjoy the fullest share of sun and light. In either of these houses, and in plant-hot-houses of every description, a sufficient number of the upright and sloping sashes should be made moveable, for the admission and regular circulation of air in the better seasons of the year; and ventilators should be placed at regular distances all round, for the purpose of airing and ventilating them in the winter months, or at times when it may not be safe to open the lights. Such a house as either of these, would form a very complete receptacle for a handsome and pretty extensive collection." (Kai. and Villa Gard. Direct.)

6171. The orangery is the green-house of the last century, the object of which was to preserve large plants of exotic evergreens during winter, such as the orange tribe, myrtles, sweet bays, pomegranates, and a few others. Geraniums, heaths, fuchsias, and other delicate plants requiring much light, were then unknown. The orangery was generally placed near to or adjoining the house, and its elevation corresponded in architectural design with that of the mansion. From this last circumstance has arisen a prejudice highly unfavorable to the culture of ornamental exotics, namely, that every plant-habitation attached to a mansion should be an architectural object, and consist of windows between stone piers or columns, with a regular cornice and entablature. By this mode of design, these buildings are rendered so gloomy as never to present a vigorous vegetation, and vivid glowing colors within; and as they are thus unfit for the purpose for which they are intended, it does not appear to us, as we have already observed at length (1590.), that they can possibly be in good taste. Perhaps the only way of reconciling the adoption of such apartments with good sense, is to consider them
as lounges or promenade scenes for recreation in unfavorable weather, or for use during fêtes, in either of which cases they may be decorated with a few scattered tubs of orange-trees, camellias, or other evergreen coriaceous-leaved plants from a proper greenhouse, and which will not be much injured by a temporary residence in such places, which, as Nicol has observed, "often look more like tombs or places of worship, than compartments for the reception of plants; and, we may add, that the more modern sort look like a combination of shop-fronts, of which that at Claremont is a notable example."

Sometimes structures of this sort are erected to conceal some local deformity, of which, as an instance, we may refer to that (fig. 570.) erected by Todd, for J. Elliot, Esq., at Pimlico. "This building was constructed for the purpose of preventing the prospect of some offices from the dwelling-house. The architectural ornaments, and the roof, not being of glass, are points in the construction not generally to be recommended; but, as it was built for the purpose above mentioned, the objections were overruled. There are three circular stages to this house, which are made to take out at pleasure. The ceiling forms part of a circle, and the floor is paved with Yorkshire stone. It is fifty feet long, and thirteen feet six inches wide, and heated by one fire, the flue from which makes the circuit of the house under the floor." (Plans of Green-Houses &c. p. 10.)

6172. Of the orangery considered as a house for growing the orange tribe, as a dessert-fruit, we have already treated. (5950.)

6173. A recent and very considerable improvement in the construction of green-houses and orangeries consists in forming the shelves and stages of thin plates of stone, instead of boards; and very frequently the flag-stones are hollowed out, so as to leave a raised margin of half an inch or more, for the purpose of retaining moisture, preventing dripping, and raising, when the air of the house is warm, a general steam or dew. This may be considered, on the whole, as a real improvement, a proof of which is the readiness with which it has been adopted by nurserymen and practical gardeners. A substitute consists in raising marginal slips of boards to wooden shelves, and covering the board with a thin layer of gravel or scoria.

6174. The conservatory is a term generally applied by gardeners to plant-houses, in which the plants are grown in a bed or border without the use of pots. They are sometimes placed in the pleasure-ground along with the other hot-houses; but more frequently attached to the mansion. The principles of their construction is in all respects the same as for the green-house, with the single difference of a pit or bed of earth being substituted for the stage, and a narrow border instead of surrounding flues. The power of admitting abundance of air, both by the sides and roof, is highly requisite both for the greenhouse and conservatory; but for the latter, it is desirable, in almost every case, that the roof, and even the glazed sides, should be removable in summer. When the construction of the conservatory does not admit of this, the plants in a few years become etiolated, and naked below, and are no longer objects of beauty; but when the whole superstructure, excepting the north side, is removed during summer, the influence of the rains, winds, dews, and the direct rays of the sun, produce a bushiness of form, closeness of foliage, and a vividness of color, not attainable by any other means. We are decidedly of opinion, therefore, that a conservatory of any of the common forms, unless it were one devoted entirely to palms, ferns, scitaminea, or other similarly growing plants, should always be so constructed as to admit of taking off the sashes of the roof and the front; and if it were a detached structure in the flower-garden, we should prefer a plan that would admit of the removal of every thing excepting the flues and the plants. There is an old conservatory of this sort in the flower-garden at Nuneham Courtenay, planted with orange-trees; and when the roof is removed, the flues, border, and bed are covered with turf, so that the trees appear as if planted in the open garden. The trees have stood there for upwards of half a century, are vigorous, and bear annually abundance of fruit.

On the other hand, there are two conservatories at Knowle, with roofs fixed, or partially opening, which have not been erected more than four years, and in which the plants are already etiolated, and the lower branches dying off. When a conservatory is glazed on all sides, it should, if possible, be placed south and north, in order that the plants on both sides of the pit should equally benefit from the sun; when placed against a wall, the glazed side may front any quarter except the north. But as the removal and replacing of the roof of such immense conservatories as are sometimes attached to man-
sions (fig. 571.), is attended with considerable expense, risk of breakage, and what is of still more consequence, risk to the plants, if they happen to be uncovered too soon in spring, or left too long uncovered in autumn, we would recommend the polyprosopic roof (1610. and fig. 261.) as by far the most perfect description of a hot-house roof that has yet been devised. With such a roof, the plants within may, at any time, in a few minutes, be as completely exposed to air, rain, dew, and sun, if these exist without, as if the roof were removed; and again, in a few minutes, they may be completely shut up. The improver who shall erect an extensive conservatory of this kind (fig. 571. a), and apply to it the regulating apparatus of Kewley (fig. 217.), will find himself in possession of the most unique and complete plant-structure in the world.

6175. The conservatory in comparatively humble and economical residences (fig. 572.), may consist of a number of rectangular sashes, connected and supported by means of light iron rafters. In the beginning of summer, the sashes may be removed and applied to the ripening of peaches, vines, or figs against walls, or laid over excavations in the form of pits, containing melons, cucumbers, &c. The light iron frame-work may either be removed, or remain, and be disguised by annual creepers, or by vines of the narrow-leaved sorts. Sometimes a cistern is placed in the conservatory for growing aquatics, and containing a few gold-fish; but as there are very few exotic aquatics which will thrive in the temperature of the green-house, this is seldom requisite, unless as a decoration, and for the use of the water in culture, and the appearance of the fishes. The temperature of conservatories being the same as of green-houses, the same proportion may exist between the flues and volume of air to be heated.

6176. The dry-stove is chiefly devoted to the culture of succulents. In design it need not differ from the green-house, unless, perhaps, in the stage (fig. 573. a) being placed somewhat nearer to the roof. The name and character of this structure is derived from the higher degree of heat generally kept in it, and from the air being less moist than in the bark-stove, where more water is used, and consequently more vapor generated. The volume of air to be heated by one fire in the dry-stove, should not exceed two thirds of that to be heated in a green-house or conservatory, similarly constructed and situated.
6177. The bark or moist stove differs from the last only in having a pit (fig. 575. b) for bark or other fermenting matter instead of a stage. This pit may be from two and a half to four feet deep, according as bark or leaves are to be used, the latter material requiring the greatest depth. It is commonly surrounded by a thin brick wall, but, in elegant structures, planks of stone, or plates of slate or cast-iron, are to be preferred, as a higher finish, and occupying less space. The roof, when necessary, may be supported from the iron columns from the middle of the pit. (fig. 574. a) Shelves may be placed against the back wall (b), and occasionally a narrow-leaved creeper run up the roof (c). Such is the common interior arrangement of a botanic stove, as may be exemplified in that designed by Aiton, and erected by Todd, in the royal garden at Frogmore. (fig. 573.) We may add, that houses of this description are generally placed east and west against walls, on account of the shelter thereby obtained during winter, when a high degree of heat is kept up within, while the cold is excessive without. There are exceptions, however, in the plant-stoves of the more recent public botanic gardens, especially those of Dublin and Liverpool, which are placed with their ends to the south, and in the immense palm-house erected by Messrs. Loddiges, which stands east and west, and is glazed on all sides. In private flower-gardens the hot-houses frequently consist of a range (fig. 575.) containing a green-house (a) at one end, a dry-stove (b) at the other, and a stove (c) in the centre. By this disposition the stove is easier kept up to the required temperature, though it loses the full influence of the light at the ends. In general, a stove requires double the number of fires required to a green-house of the same size.

6178. There is a peculiarity in the construction of plant-stoves which deserves particularly to be noticed; namely, that fewer openings for the admission of air are requisite than in any other hot-house, excepting the pine-stove. One reason of this is, that the degree of heat which must at all times be kept up in the enclosed atmosphere, is so much greater than that of the open air, that the difference in the specific gravity of the two fluids, when permitted to mingle by opening two or three sashes, produces a more active circulation, and sooner approaches to an equilibrium of temperature: another is, that however numerous the openings in the hot-house roof may be, they could seldom be made use of without reducing the house too low a temperature; and a third is, that the plants being mostly kept in pots, and many of them, as the palms, being of slow growth, they are not so apt to etiolate as those of the green-house and conservatory. Hence it is, that the roof of a botanic stove may generally be erected at less cost than that of a green-house or conservatory; but particularly where iron is employed, and the curvilinear principle adopted.

6179. Houses of magnificent forms, and almost as light within as in the open day, might thus be constructed for the growth of palms, scitaminee, bamboos, and other tropical trees to be planted in the ground, as in the conservatory. These might also be detached in the flower-garden (as figs. 10. and 20. in Sketches for Curvilinear Hot-houses), or they might form an appropriate appendage to a palace in the oriental style. (fig. 576.) Indeed, there is hardly any limit to the extent to which this sort of light roof might be carried; several acres, even a whole country residence, where the extent was moderate, might be covered in this way, by the use of hollow cast-iron columns as props, which might serve also as conduits for the water which fell on the roof. Internal showers might be produced in Loddiges' manner; or the roof might be of the polyprosopic kind, and opened at pleasure to admit the natural rain. Any required temperature might be kept up by the use of concealed tubes of steam, and regulated by the apparatus of Kewley. Ventilation also would be effected by the same machine. The plan of such a roof might either be flat ridges running north and south (fig. 577. a), or octagonal or hexagonal cones (b), with
ORNAMENTAL HOT-HOUSES.

817

a supporting column at each angle, raised to the height of a hundred or a hundred and fifty feet from the ground, to admit of the tallest oriental trees, and the undisturbed flight of appropriate birds among their branches. A variety of oriental birds, and monkeys, and other animals, might be introduced; and in ponds, a stream made to run by machinery, and also in salt lakes, fishes, polypi, corals, and other productions of fresh or sea water might be cultivated or kept. The great majority of readers will no doubt consider these ideas as sufficiently extravagant; but there is no limit to human improvement, and few things afford a greater proof of it than the comforts and luxuries man receives from the use of glass — a material, as Cuvier observes (Magasin Encyclopédique, 1816), manufactured from seemingly the most useless débris of our globe, and an insignificant plant (salicornia) found on sea-shores. In northern countries civilised man could not exist without glass: and if coal is not discovered in these countries, say in Russia, it may at some future period become a question whether, instead of separate fires and stores, double windows, &c. the most economical mode of procuring a proper temperature will not be by at once to cover whole towns with immense teguments of glass, and heating by steam or otherwise, the enclosed air common to all the inhabitants; or where glass was considered too expensive, whole villages might be covered with a roof of boards, and lighted night and day in the winter season by gas previously obtained from the fuel used to produce the steam: or the gas might be employed for heating, either by the generation of steam, or passing the air heated by the flame through metallic tubes.

6180. The aquarium. The greater number of exotic aquatics being stone plants, a cistern of water for their culture is commonly placed in the bark-stove, generally at one end of the pit, and so as to be as near the light as possible. The Duke of Marlborough, however, and some others, have erected houses on purpose for this beautiful class of plants, substituting a large cistern for the bark-pit. The aquarium, at White Knights, (fig 578) built by Todd, "is constructed with a span roof of glass; the sides and ends are also of glass, as low down as the top of the flue. A cistern occupies the interior of the house, having a walk round it; it is lined with lead, and filled with a mixture of mud and water, proper for the reception and growth of such plants as require aqueous nourishment. A flute goes round, directly under the bottom of the cistern, for the purpose of keeping the water of a certain temperature. Another flute goes round the house above ground, and terminates in a chimney at the north-west corner. The bottom of the cistern, to receive the lead, is formed with slates, supported by transverse bars of cast-iron; a bottom of wood would have been more convenient for laying the lead upon, but as the flues are so near the bottom of the cistern, danger of fire was apprehended. The cistern is supplied with water by means of a pump placed at a convenient distance for that purpose." (Plans for Green-Houses, &c. p. 17.) This aquarium suits very well for such aquatics as grow to some height above the water; but for those whose leaves float on its surface, as is the case with the most numerous and beautiful genus of this class (Nymphæa), it is too far from the light. A more perfect plan would be, to have the cistern close under the front glass, and to have that glass rather flat, say at an angle of 15°; or two cisterns might be formed, one in the back part of the...
house for tall plants, and the other in front for floating foliage, with a broad path between. But the most elegant plan would be, to have a circular house, glass on all sides (fig. 579.), to have a cistern in the middle, and Eolians from it, and so arrange them as to imitate the effect of the motion of water in the central cistern, the mould or pots in which the plants grow might be placed on a bottom (a), apart from that of the cistern (b), and this bottom being on the end of an upright shaft, might, by the aid of proper machinery in a vault below (c), be kept in perpetual motion, according to the wishes of the gardener, which might be placed on the circumference of the bottom (d), and those requiring less agitation towards its centre (e). If reversed motion was required to imitate tides (where marine aquatics were cultivated), nothing could be easier than the path of the pots to be used in the framework by another still more simple plan known to every engineer, it might be changed seldom, say only once or twice in twenty-four hours. If a rapid and tortuous motion was required, then let the bottom on which the plants are placed, be furnished with small circular wheels (f) placed on its margin, wheel-shaped teeth will be ground into the edges with the corresponding row of teeth fixed to the inside of the wall or side of the cistern, into which they are to work like a wheel and pinion. By this means, pots of plants set on the small wheels, will have a compound motion, one round the centre of the small wheels, and another round that of the large bottom, something of the effect of the motion of the tides of the ocean. It is like the wind into an aquarium, that exotic aquatic fowls and fishes might be kept in such an aquarium, and either of the sea or freshwater rivers, according as salt water or fresh was used. It may be shown that the Machinery would in every case be simple and troublesome; but the power requisite is so very small, that it might easily be obtained by machinery on the principle of the wind-up jack, as was used by Deacon in his ventilating Eolians. (Rem. on Hot-h. 68.) This kind of mechanism very seldom goes out of order, or requires repairs, and would require no other attention than being wound up twice in twenty-four hours, and oiled occasionally. The same vault that contained it might serve for the furnace or boiler for heating the house. 6181. Wind. If instead of water in a circular cistern with its bottom so constructed, we suppose air, then the same arrangement would serve for producing artificial wind to plants, the beneficial effects of which in producing bushiness and strength of stem are well known. The motion thus given would probably be easier than the sort of wheel used in the central cistern, from getting mouldy and damping off, and by moderating the growth, and preventing the etiolation of others. For this purpose the machine might be considered as a kind of hospital, and the plants being in pots, might be set on either large or small wheels, and kept there in motion for a longer or shorter period, according to circumstances. 6182. The substitution of fire-heat for that produced by the fermentation of vegetable substances, is a recent innovation in the construction of plant-stoves. This has been done by heating the air of a vault or chamber, with steam, rather by a furnace, in either a steam chamber, or by simply filling the vault with them. In some cases, also, flues or steam-pipes have been conducted through the vault with a tend to prolong its heat. The mode by heating an air-chamber below the pit was carried into execution by us so long ago as 1804, at Gentlur (Tr. on Hot-h. p. 249); and more recently on a larger scale, for the purpose of growing Cucumbers. (Tr. on Cucum. p. 11. fig. 3.) A plan very similar to the last has been adopted by Kent (Hort. Trans. ii. 289, and iii. 287.), who at first plunged the pots in a bed of sawdust over the vault, thinking thereby to avoid the worms and insects that generate in decaying manure, but he found, however, that with them generally, as freely as in any thing else, and has therefore given up the practice of plunging altogether, setting the pots on a thin layer of coarse sand placed over the pavement, which forms the roof of the hot air chamber. Thus situated, the plants are not apt to run through the bottoms, and over the tops of the pots, as they are always exposed to any which always escapes from them, or which they may be removed or required to be shifted. After above a year’s trial, he says, “I think I can with certainty pronounce that plunging is not only unnecessary, but really worse than useless to plants, except where they have been injured and require to be drawn.” A very obvious extension of this principle was the device of bottom heat altogether, and the substitution of a bed of scoria or gravel for the bark-pit. This has been done extensively by Messrs. Lodidge, Kent, the Comte de Vande, and various others, with perfectsuccess as far as respects large plants; but most stone-vaults require to be originated and brought forward till they are one or two feet high in bottom heat. By this means, the temperature, and the temperature over the leaves, that sort of moist heat is produced which seems most congenial to vegetation, and it may, we think, be assumed as experimentally proved, that where such heat is produced in plant-stoves the bark-pit is unnecessary for all general purposes. Kent, “asserts the importance of preventing the earth from being dried up by the heat, and leaves receive a greater degree of heat from the atmosphere than the roots can possibly do; it appears extraordinary that a system of management so directly opposite to nature should have ever been adopted, or that it should have been so long practised. If a quantity of earth was to be raised from the root of any tropic plant, there is no doubt in its native situation, they would be the first to escape, as they are of the air, therefore the roots of the plants in a stew ought not at any rate, to receive more warmth than their other parts.” (Hort. Trans. iii. 286.) 6183. A propagation-house is a requisite appendage wherever a general collection of exotic plants is maintained; and the proper situation for it is in the reserve-garden. Such a house, like the houses used by nurserymen, does not require to be so light as fruiting or flowering houses; it may be little more than a large pit with the roof very flat (say from 12° to 15°), in order that all the plants may be near the glass; it should contain a bark-pit, raised to within eighteen inches of the glass in front, and 24 feet behind, a broad stone shelf in front, and two or more shelves in the back of the house, close under the roof, that is, over the path and flue. All shelves in hot-houses, it may be observed, whether of stone or timber, ought to have narrow ledgments along their edges, not less than an inch deep, by which the water which escapes through the bottoms of the pots is not only prevented from dropping, but retained to generate a salutary coolness and moisture. The fire-place should be formed at one end of the front (say the south-east corner), and the flue conducted along the front from about nine inches or a foot from the parapet, and so along the opposite end and back wall, till it terminates at the extremity of the latter, or the north-east corner. The door may be formed in the back part of the end in which the furnace is placed, and the path which surrounds the pit, should be made sufficiently low to admit of head-room. This plan may in some cases be doubled; that is, a similar arrangement of flues, &c. may be erected alongside the other, that is, the north side, with a moveable boarded partition between them. The house fronting the north may be used for striking cuttings, or raising seedlings, and that fronting the south, for
nursing the plants so raised, till they are fit for removal to the principal green-houses and stoves. The partition is made to remove, in order to admit or exclude the sun's rays to the back-house in spring or autumn at pleasure.

6184. We have already stated that we consider steam the best vehicle for heating hot-houses of every kind, especially where there are several connected together. Thus where all the hot-houses of a residence are connected with the mansion, both the latter and the former, with drying rooms, hot water or vapor-baths, steaming apparatus for horse-food, poultry-houses (under particular circumstances), and various other appendages might be heated as well as the hot-houses. The spare steam might be employed as the first power to machinery, to raise water, to drive a mangle, &c. and a gas apparatus might be added, to admit of lighting up the whole. Repton has given a plan well adapted for this purpose. (fig. 580.) At one end of this design an aviary (1) is surrounded by a conservatory (2), and joined to a glass passage for flowers (3), which leads successively through an orangery (4), lobby (5), music-room (6), library (7), print and picture-room (8), breakfast-room (9), anti-room (10), dining-room (11), hall (12), and peach and green-house (13). The whole length of this range is three hundred feet. Even single stoves or green-houses may be more agreeably heated in this way than by smoke-flues, which are very generally attended by a bad smell, and vapors of carbonic acid and hydrogen. A very neat example of this kind (fig. 581.) is given by Hayward. (Hort. Trans. iv. 434.) "It is erected in a small conservatory, the boiler (A) contains about thirty gallons, and the pipes (b, c) are three inches in diameter, and so laid as to have thick planks resting on props (a, b, c) placed over them, to form the pathway round the house. Chambers are formed round the pipes, communicating with the external air, by surrounding them with larger pipes (c, c); and by means of small pipes (b, c) as much heated fresh air can be admitted into the house through different apertures (e, k) as can be wished." By laying the pipes with a declination of a few inches from their departure from the boiler till their return to it, the water of condensation is returned through a valve (A b), which is a very considerable advantage; but this valve is much better placed in a close box outside the boiler, (an improvement made by Messrs. Bailey,) as admitting thereby of examining it with ease when out of repair. The air-cock (e), safety-valve (o), steam-gauge (n), and water-gage in Hayward's boiler, do not differ from the usual construction. The mode here described of admitting heated air, we would observe, must be used with very great caution, for we know experimentally, that no mode is more liable to overheat the atmosphere of the house when the fire or steam is brisk in the beginning of the night, and overcool it when the fire declines towards the morning. We have the same objection to Walker's Improved Construction of Hot-house Flues, as described (Hort. Trans. iv. 237.), by A. Seton, Esq. Here a cast-iron flue is enclosed in one of masonry, and the vacuity between them communicates with the open air at the stock-hole, and with the air of
the house at certain distances, by means of apertures in the top of the flue. The argument in favor of this arrangement, is that usually given for vats in a greenhouse connected with flues, as adopted by Stewart, Gould, and various others (Tr. on Hot-houses, p. 132.), viz. that "the current of external air, by commencing, when cold, at that part of the flue which is hottest, takes up the heat there where it is least wanted, and carries it to those parts at a distance from the furnace where it is most needed; and as the flue is to be chiefly opened in the latter situations, to permit its escape, it diffuses a nearly equal warmth over the whole house." Every thing in this plan evidently depends on the management of these valves; if they are left open during the night, the risk above stated is incurred; if during day, less heat being wanted, little advantage is obtained. In stoves, however, this plan, under judicious management, might be useful; but it must never be forgotten, that air can be rendered much hotter by a fire-flue than by a steam-pipe, and hence the danger to the plants. No one was ever more sanguine as to the advantages to be derived from furnace vats and air-flues than ourselves (see Tr. on Hot-houses); but after twenty years' experience, we must acknowledge that they are so liable to produce accidents, either by admitting smoke or burning up the plants (as the phrase is), that we now seldom recommend their adoption.

6185. Various pits and hot-beds will be required in the reserve-department of the flower-garden, for forcing shrubs and flowers, raising annuals, &c.; the construction of which having nothing peculiar, need not be here detailed. (See 1591. et seq.)

6186. The idea of cold-houses seems to have been first suggested by Sir W. Chambers (Dissert. on Orn. Gard. p. 4., and it may be worth while to submit some hints on their construction for such amateurs in this country as may be curious in the cultivation of musci jugernanni, and other cryptogamous vegetables which grow in the lowest temperatures; and for botanists in warm climates, who may cultivate not only mosses, but the most delicate of perennial plants of elevated regions or northern climates; as for example, of the British or Swedish alpines in Spain, or in the south of Italy. The simplest form of a cold-house may be a vault of rustic masonry open at one end, along the floor of which a rill of water may pass, and from every part of the ceiling water may drop on the floor or bed, and descend to the rill in the centre. This is an obvious imitation of the dripping rocks found in tracts of country abounding with calcareous rocks, of which, as an example, we may cite the dripping rock at Knaresborough, and the dripping cave near Rousseau's walk at Lyons; in which last, on the 19th day of June 1819, we found the thermometer at 48°, whilst in the open air, under the shade of the adjoining mulberry-tree, kept at 72°. Various mosses and ferns were in luxuriant vegetation in the interior of the cave; and some sorts of ferns near its mouth. Another imitation of such caves might consist of an open grove of elms or oaks, among the lower branches of which lead pipes pierced with small holes, in Lodge's manner (1688), might be fixed horizontally at regular distances, and these being supplied, during the warmer months, with water from a proper reservoir, would furnish a continual shower, which, with the assistance of the small rills furnished by the collected rain thus produced, would lower the temperature of the atmosphere sufficiently for the growth of such mosses and ferns as do not require much light; and the margins of the grove might be devoted to plants of a milder climate requiring a low temperature and moist atmosphere. But a more perfect plan would be to form a house like a large pit, with a double glass roof, fronting the north. Over the outer roof should be a system of pierced pipes kept cool by a continual shower during sunset, and at the top of the back wall an arrangement whereby two or more separate and concentric covers of canvas could be let down to exclude the sun during the day. Instead of flues of masonry, large tubes of lead or cast-iron should surround the house, to be kept cool by a continual stream of water passing through them. The pit might contain a large metallic easter, filled with ice, to be renewed when thawed, &c. It would be advancing too far into the region of speculation, to enter into particulars relating to minor details that would be necessary to render such a house complete; let it suffice to say, that such houses might be erected in Britain, or the south of Europe, so as to produce a temperature of 32 degrees throughout the year. This would admit the cultivation, in pots and on pieces of rock, of lichens, mosses, and all of the more perfect plants which grow in the regions of perpetual snow. (See 1808.)

Of the General Culture and Management of the Flower-garden and Shrubbbery.

6187. The cultivation of the flower-garden is simple compared with that of the kitchen-garden, both from its limited extent and the general sameness of its products; but to manage it to perfection requires a degree of nicety and constant attention beyond any other open-air department of gardening. As the stalks of flowering plants shoot up, they generally require thinning, and props for support; and the blossom, both of plants and shrubs, no sooner expands than it begins to wither, and must be cut off, unless, as in some of the ornamental shrubs, they are left for the sake of the beauty of their fruit.

Weeding, watering, stirring the soil, cutting off stems which have done flowering, attending to grass and gravel, must go hand in hand with these operations.

6188. With respect to the general culture and manuring of the soil, it should be subjected, as far as practicable, to the same process of treading to different depths as that of the kitchen-garden. In the shrubbbery this cannot be done, but it, and also the earth compartments of the flower-garden, should be turned over a spit in depth, and some vegetable mould, or very rotten cow-dung, added occasionally. Every two or three years the plants in the flower-garden should be taken up and reduced in size, and the beds or borders trenched, say one time at two spits deep, another at three, and so on (see 2541), adding enriching compost or manure completely rotted, according to circumstances. If, instead of t trenching, the old earth were entirely removed, and replaced by good loam from a dry upland parterre, the improvement would be still greater. Most herbageous plants flower well in such loam, and for the more cultivated sorts, as border pinks, auriculas, &c. that require a rich soil, a portion of enriching matter could be added to each plant as planted, and a corresponding attention paid to such as required peat-earth, sand,
clay, or lime. In the shrubbery, a similar renewal of soil, and attention to the soils required by particular shrub-plants, is also required, at least in front, where the more delicate shrubs naturally rank, and where the herbaceous plants are chiefly arranged.

6189. With respect to the times of planting, or sowing, and manner of cropping the flower-garden and shrubbery, the greatest part of the surface being covered with shrubs or plants of perennial duration, very little cropping is required, and as a substitute for a rotation, recourse must be had to the renewal of the soil as recommended above. Annuals are sown at various periods from February to June; but for the principal show, generally in March; the half-hardy kinds in green-houses and hot-beds in the reserve-departments of the garden during March, and in the, early spring, when they are to flower in April and May, and later sowings and transplantings are made to procure a protracted display. Biennials and perennials of the fibrous or ramose root kinds are transplanted from the reserve-department in September or in March; and such bulbous roots as are annually brought up, are generally replanted in November or February. When bulbs and other florists' pansies are cultivated in beds, a rotation may be adopted as far as respects them: thus the hyacinth, tulip, &c. may be succeeded by annuals, and those by the dianthus tribe, or dahlias, &c.; but in borders and compartments planted in the mingled manner, as well as in shrubberies, a rotation is out of the question. Particular care is required to remove weak, ill-conditioned, or ill-flowering plants, and to replace them by others of the same height and color. This may be done at all seasons of the year by the use of the transplant; but the better mode is to have always an ample stock in the reserve-garden, of all the colors and heights, both of hardy perennial plants and low shrubs, (of all the sorts is unnecessary,) in pots, and whenever, or, when any plant is in flower, a defect appears, it can be remedied at once by turning the plant out of the pot into its situation in the border. Independently of disease or accident, fine showy species, answering in general color and height, may thus at pleasure be substituted for such as are less showy, or less to the taste of the spectator.

6190. Ornamental plants, whether shrubby or herbaceous, require to be pruned, trained, thinned, and dressed, according to the sort of beauty or effect expected from them. If they are grown chiefly on account of their blossoms, then the utmost must be pruned on the same general principles as fruit-trees; but little more than thinning out weak and crowded shoots will be required where they are grown chiefly on account of the beauty of their foliage; and still less where the tree or bush is planted for the sake of its natural shape. It is customary in some places to apply the hedge-shears to shrubs; but this is a barbarous practice, destructive of all the beauty, which ought to be exploited, unless it be shown, in imitation of the antient style, trees are to be trained in artificial shapes. Herbaceous plants require little pruning, but nevertheless something in this way may be occasionally required on the same general principles applied to trees. Where very large flowers are wanted, it is obviously advantageous to prevent their being hidden by the growth of branches, or to make a number of these, or in more shoots and leaves. Top-heavy plants, as some thistles, solidages, &c. may require to be lightened, and almost all are benefited by thinning out a part of their shoots. In some annuals, thinning is effected both by eradication and pruning, and generally by more delicate methods by pinching off the young shoots, when an inch or two high. Crape myrtles, climbers, and shrubs planted against walls or trellisses, either on account of their rarity, delicacy, or to conceal the object against which they are placed, require different degrees of training; those which attach themselves naturally, as the ivy, merely require to be occasionally guided so as to induce a regular distribution of the shoots; the others must be treated like fruit-trees, training them, if blossoms are the object; and rather thicker, if a mass of foliage be what is chiefly wanted. Hedges and edgings require to be cut and otherwise kept in order by the obvious means. "Edgings of all sorts," Marshall observes, "should be kept in good order, as having a singularly neat effect in the appearance of a garden. The above edgings will be sometimes, and the live edgings often, want putting to rights; either cutting, clipping, or making up complete. Where there are no edgings, or but weak ones, let the earth bordering on the walls be kept firm, and now and then worked up by line in moist weather, beating it smooth with a spade." [Introd. 57.]

6191. Grass-plots require to be regularly mown at least once a fortnight, and whereas extraneous plants, of broad-leaved kinds, make their appearance, as plantago, comfrey, &c. they must be carefully removed. Worms will be gathered by hand before sunrise, or their casts swept off with the wire besom (1921.), and then the ground waved with lime-water. Rolling and watering must be applied according to circumstances, and nothing neglected to ensure that deep-green color and velvet texture which is, or ought to be, the characteristic of the British lawn, and which is indeed the pride of our island.

6192. Various tender sorts of plants and shrubs require protection by one or other of the different utensils, screens, or other contrivances (2506. to 2518.) destined for that purpose. Alpine plants require protection from cold, by covering with snow, or by hand-glasses, or frames during winter; and from heat, by screens to produce shade during summer. The roots of many sorts require to be protected by ashes, rotten, or chaff, to be spread on them; and the tops of others both shrubs and plants, known as the "fumitory"

6193. Water, whether as an ornamental feature, or as an aquarium, should be kept clean, both of water and weeds. Of aquatic weeds the most troublesome in small aquaria are the water fern, and hyssop, which can only be removed by hand, or by entangling them with a rake or broom. The larve of numerous land-insects depositing their eggs on water or in the muddy sides of ponds and ditches, as the elephant-hawk-moth (Sphinx Espina Protrusa) (fig. 529, 530.); the dragon-fly (Libellula, 1.), and many others. Of the aquatic kinds are the well known water-lily, of which some species (255.) glide over the water, and are by many considered rather ornamental than otherwise, and others live entirely under it, and feed on the roots of plants. To de-
...stroe, or at least greatly to keep under all aquatic insects, an effectual mode to dry the pond for a day or two; but in the case of an aquarium it cannot be done; fish and frogs, their natural enemies, must therefore be encouraged, in order that they may attack them.

6194. *Insects and vermin.* These must be kept under in every part of the flower-garden and shrubbery, and we perfectly agree with the author of the *Florist's Manual,* that "the simple and laborious mode of picking away the animal, is the only one to which recourse can be had with permanent advantage. To give full efficacy to this method of rescuing plants from caterpillars, snails, &c. our attacks must be made upon them at particular seasons, which can only be done from such a knowledge of their history, as shall enable us to have swarms of them destroyed in the destruction of an individual of the species. Without, however, much research into their natural history, we may, from common observation, understand that in the winged insect we may free our plants from an insidious tribe of those which crawl, and which, in that reptile state, have the capacity of devouring the whole product of a garden. The two periods of change of form in the caterpillar species, seem to afford the most advantageous times to put an end to their existence. Thus, the ephemeral butterfly; if timely attended to, we may destroy the animal before it has acquired the power of disseminating its young progeny; and, in the intermediate and voracious state of caterpillar, every single one which is prevented attaining the winged form, preserves our flowers from a host of enemies. The green caterpillar is the most common foe to our flower-borders and in autumn attacks the branches of migratory in such numbers as to afford an easy opportunity of their destruction. A more persevering enemy, and more difficult to exterminate from gardens, is the snail (*Helix*) and slug (*Limax*); which, forming their habitations under the soil, attack the roots of the flowers, and frequently destroy them before the gardener can be aware of the mischief, that too often becomes visible only when past reparation. Under a vigilant eye, however, plants will not twice suffer from the enemy not being discovered; as the symptoms of his vicinity may be marked by flowers perishing as they first emerge from their buds or bulbs, by leaves or petals being pierced in small holes, or having the appearance of being gnawed in growth, or from almost any failure in vigor which cannot be accounted for by external causes. In cold and dry weather the snail rarely appears, but after warm showers it may generally be found; early in the morning, and about the close of evening, are the usual times of their coming abroad, when they may be picked up in large quantities. They will, however, frequently molest a plant for a length of time without being visible, in which case, when there is reason to suspect their hidden attacks, the only method to entrap them is to place a common garden-pot over the infested root, and it will rarely occur that the enemy is not discovered, as snails fasten themselves to the sides or tops of boards, or mats, or cabbage-leaves, so placed, and thence are easily taken. In droughty seasons it will be of use to water the plant before it is covered, as the moisture of the earth will be an additional motive of attraction to draw the animal from his hiding-place. The smaller insects which infest rose-trees, and some herbaceous plants, can only be kept within moderate bounds by sweeping them from the branches, or by cutting off those whereon they are found in most profusion. In carrying off these diminutive enemies, birds are peculiarly serviceable. Insects generally attack those plants which are least vigorous; and the reason of the selection of such leaves as are beginning to decay may be, that in their declining...
state they have usually a peculiar sweetness, probably perhaps owing to some saccharine juices which are preparing for the nutriment of the bulb or bud which is forming in their bosoms, for the nascent vegetable derives its sustenance from the recrement of the one in which it takes root. The bulb of the gardenier will of course take care not to destroy on account of its use; and it may be a question whether some species of the butterfly, moth, dragon-fly, &c. should be destroyed on account of their beauty. Some species of these genera are highly beautiful, as the four-budded orange-butterfly (Lepidoptera, 1.), and the swallow-tailed butterfly (Papitita Machaon, 1.) (fig. 584.), which is reckoned the most superb of the British species. It is very local, but occurs near Bristol, Beverley, and in the New Forest. The larva feed on umbelliferous plants; the caterpillar is green, banded with black, marked by a row of red spots. It changes into the chrysalis state in August. Two broods of the first appears in May, having been in the pupa state all the winter, and the other in August from the pupa of July. (Sannowell.)

6195. The cutting off flower-stalks, decaying flowers, leaves, &c. is to be done in most cases immediately after the flowers are faded; but there are exceptions where the leaves on the lower part of flower-stems may be requisite to strengthen the root, and where, as in the case of steppe, some convallarias, eringoes, &c. the parts of the flower are persisting, or the fruit or seed-pods are objects of beauty. The leaves of bulbous-rooted plants, and such others as are not prolific in foliage, should be carefully preserved till they have begun to decay; and, indeed, the base or root-leaves of no plant whatever should be cut off till this is the case, unless for some particular object. Every single flower, as soon as the petals begin to droop, should be pinched off, and especially every flower of the double kind. Every rose, when it begins to droop, should be elipt off near to the foot-stalk of the one which is about to succeed it; and when the last of the corymb has done flowering, then the common foot-stalk should be cut off back to the first strong leaf-bud: nothing is more unsightly in a flower-garden than rose-bushes where this has not been attended to. By employing women or apprentices to go over the whole pleasure-ground every morning during the four summer months, to attend to this business, it may be completely accomplished at very little expense. These and other points of management, we know, are considered needless niceties by many gardeners: but what is a flower-garden unless it is kept with the utmost nicety? Others will tell you, they have not time for such things; but where there is a real taste for neatness, time will be found. "No gentleman," Sir G. Mackenzie observes (Caled. Hort. Mem. iv. 194.), "ought to keep a gardener who does not understand that there is time enough for every thing, provided that time is not wasted, but properly regulated, and nothing too long delayed."" 6196. Gathering flowers. Gather, if possible, only from the reserve-garden; for if the main borders and compartments are managed as they ought to be, much gathering will disfigure the plants. Always use the knife, and prefer such as are coming into flower, rather than such as are fully expanded. If possible, gather from crowded plants, or parts of plants, so that every gathering may operate at the same time, as a judicious pruning and thinning.

6197. The French rose-gatherer presents a refinement in floricultural instruments highly characteristic of its origin. The general form of this little engine is that of a pistol: it has a handle and trigger like it, and a cutter in the manner of the wire pliers, or flower-gatherer (fig. 152.,) disguised as a barrel. A rod, anwering to the ramrod, connects the pincers with the trigger, which, last being pressed, opens the pincers, that is, charges the pistol; the operation which presents the plant to be gathered is the same. In the position as at the precise point of the stalk deemed proper: things being thus adjusted, the trigger is drawn, and the deed is done. — Of course this instrument, like a number of other horticultural toys manufactured by the Parisians, is chiefly pour les dames.

Grafting, budding, laying, &c. Operations of this sort require to be performed in the flower-garden and shrubbery, for enlarging, renovating, and otherwise improving shrubs and plants, or introducing new sorts; they are also required for the common purposes of propagation.

6200. Ordering seeds, bulbs, and plants. This business is much simpler in the flower than in the kitchen garden. For flower-seeds of most sorts, an order is simply given for a paper of a sort; mignonette, lupins, sweet peas, and a few others, may be ordered by the ounce; bulbous roots are generally ordered by number, either of mixtures or single sorts; and herbaceous plants, shrubs, &c. by name and number, or by the hundred or dozen in mixture. See the priced catalogue of any nurserman.

6201. Neatness has been already a good deal insisted on in different parts of this work. We repeat, it is the dress and visage of gardening, and if necessary anything else, so in the flower-garden without the most vigilant attention to this point, at all times, is unworthy the charge. The first thing is to have a quick intelligent eye, so as instantly to perceive what is wanting, and the second is to be possessed of that principle of activity which immediately sets about supplying the want. Many gardeners have certain times for cleaning up, &c. and will go fifty times past a weed, stone, dead leaf, or some such article, which disfigures or injures a scene, without removing it, merely because the time for cleaning, &c. has not come. This is most abominably formal conduct, deserving the severest reprobation. A gardener ought to have his eye, his heart, his head, his hands, all ready for action at all times, places, and seasons, when within the precincts of his garden. Let him drown this incessant care in his own way when he is without his scene of business, or in the hours of rest and refreshment; and let him not undertake it without adequate terms of remuneration. (See 2353. 2372.)
6202. The general culture of floricultural hot-houses respects soil, choice of plants, planting in pots or beds, and arranging: after offering some remarks on these heads, we shall submit a few as to what is general in the management of the principal floricultural habitations, as the frame, green-house, and stove.

6203. Soil for beds or borders. The first operation of the gardener, after a conservatory or stove is finished, is to fill up the beds and borders with prepared earth. These being narrow, should seldom be less than three feet in depth, the bottom should generally be paved, and sloping to a drain or drains; and in cases of very dry soils, provision may be made for the roots extending themselves beyond the area of the house. In general, however, this is not desirable in stoves, as the roots might be chilled during severe frosts; but provision may be made for their extension under the paths, and every other part of the area of the house. When a variety of plants are to be grown in such pots or beds, the soil can be fixed on that will suit them all; but if the main body be a sandy loam, then, as each particular tree is planted, a few cubic feet of this loam may be removed, and replaced by the soil best suited to the plant. The plant once established, be it what species it may, will not languish in a sandy loam, other circumstances being favorable.

6204. Choice of species and planting. The species of stove or green-house plants must depend on the sort of house, and a variety of circumstances which need not be entered into. For common purposes choose the showy-flowering, easily cultivated, and vigorous-growing genera, as geranium, camellia, fuchsia, Jasminum, &c.; or evergreens, as the myrtle, proteaceæ, &c. (choosing from the tables in Chap. X.) some plants of the principal colors to flower in every month. In planting broad central beds in a house, glass on all sides, the highest-growing kinds will be placed along the middle of the bed; but where there is a wall to the north, the highest kinds will be placed next it. With respect to arrangement, the limited space admits of very little; in general, it will produce the most showy and immediate effect to adopt the common mingled and shrubbery arrangement, which we have recommended (6193.); but as the spectator lingers longer on the pavement of the conservatory or stove, than in the walls of the shrubbery, more prolonged interest will be produced by assembling such plants as belong to one genus, or natural order, by themselves; because this will be to unite what used to be considered the desideratum of taste—unity and variety; that is, a general harmony of character in the genus, tribe, or family, and yet, when examined in detail, a distinctive character belonging to each of the individual species which compose it. It is a very common practice to plant climbers in such beds and along narrow borders, close to the upright or front glass, to be trained under the roof. We most decidedly disapprove of this plan, in almost every case, as tending to defeat the whole object in erecting such houses. Very luxuriant climbers are thus produced, but it is at the expense of light, not one ray of which, if possible, should be prevented from falling on the plants in the body of the house.

Climbers or creepers are highly ornamental, and may be planted in a variety of situations without injuring the other plants; for example, in the bed, and trained on rods, or up such props as may be necessary to support the roof; or, along the sides of a central walk in a house standing north and south, and trained over the walk on an arcade of rods; or, in a similar arcade over the back path of a single-roofed house, or on the back wall. It is a very common thing to see the ceanothus in green-houses, and the fruit-bearing passion-flowers in stoves, darkening the greater part of the roof, and the plants beneath growing or elongating fast enough, but weak and of an unhealthy languid green. It is only under the broad wooden rafters of old-fashioned hot-houses that any sort of creepers may be trained up the roof without materially injuring the plants below; and even in these cases the injury is considerable, unless they are kept within very narrow bounds. But if creepers are injurious in plant hot-houses, the introduction of vines under the rafters is still worse; for, besides, darkening the plants below more than the others with their broader leaves, the incongruity of effect produced by the attempt to unite two opposite characters, is exceedingly disagreeable, and only to be tolerated in humble economical residences, where a green-house, perhaps, is the only glass structure.

6205. Arrangement of plants in pots. Where the house and the collection are small, or the plants few and large, the same observations will apply which we have advanced on the subject of planting the beds of conservatories or stoves; but when the houses and collections are extensive, then some plan of arrangement ought to be adopted. Here, as in shrubberies and flower-gardens, there are three modes, by mingling, by grouping, and by method. For general effect the first is the best, but for prolonged enjoyment and examination in detail, the two others are greatly preferable. An abstract view of the modes by mingling and grouping might be represented by lines (figs. 585, 586.), in which, by the mingled mode, the colors are as regularly arranged as chequer-work, while, by the grouping mode (fig. 586.), they succeed each other in large irregular masses. By the first mode, there is only one plant of a color by itself; by the second, from half a dozen to three or four dozen, according to the size of the group and the plants.
CULTURE OF BOTANIC HOT-HOUSES.

586. By either mode regard must be laid to place the plants in gradation according to their size, from the front to the back, or from the lowest to the highest part of the stage, as well to give them every possible advantage as to light, as to present the greatest surface to the eye of the spectator. It is not desirable, however, to dress them so regularly, as that the general slope of verdure shall appear as if shorn or mown, for that both deprives the sides of the plants of a considerable portion of light and air, and the eye of variety of form, and light and shade; it will have a much better effect if somewhat irregular, and if here and there a distinguished individual appear above the rest as a standard.

587. In arranging by method or botanically, either the Linnean or Jussieuen classification may be adopted; the latter is unquestionably preferable, as exhibiting a more perfect relationship; and it may be considered as represented by the same lines as those delineating the mode of grouping by colors. (fig. 586.) Where the Linnean method is adopted, the classes may either be grouped in irregular roundish masses; or, as the tallest trees and lowest herbs are often placed in the same class, it will answer better to dispose each class and its orders in irregular strips (fig. 587. m. d. t. tet. pentandra, &c.), from the lowest to the highest part of the stage, by which the dwarf plants of each class may be placed in front, and the taller farthest back.

588. The botanic arrangements, it has been already observed, are only adapted for extensive collections and capacious hot-houses; on a smaller scale the mingled method, or that by grouping, will be most advantageously adopted. In the case of green-houses attached to living-rooms, and where there are reserve-houses to keep up a supply, only such plants as are in bloom should be introduced, and there the method by grouping the colors may be adopted with great effect. But whatever be the size of the house, or even the extent of a bed, or shelf, or any part of them, never let the plants be placed there in the present indiscriminate mode. In this, no regard is paid to any thing but height; or if any farther object is taken into consideration, it is to mix the kinds as much as possible, with a view, as is alleged, to produce variety. But the effect of this mixture, whether on a large or small scale, instead of variety, is sameness or monotony, which lessens interest, and finally produces indifference in the spectator. It is true, there is as great a degree of sameness in the mingled mode; but then it is the sameness of a formal and arrowed regularity; whereas, the sameness resulting from the common mode of mixture, is the sameness of affection,—a sameness resulting from an abortive attempt at something not attained. The one mode may be compared to the geometrical manner of laying out grounds, and the other to the mode by clumps and belts; both are alike artificial, but the former is avowedly so, and therefore has attained its end, while the latter affords to be an imitation of nature, and therefore disappoints. A safe rule for every gardener to adopt, whether in setting pots of plants on a shelf or a stage, however small either may be, and however limited the collection, is to keep each genus together, placing the tallest plants farthest from the eye. Sometimes this will form a thin, straggling group from the front of the shelf or stage to the back (fig. 588. petargonium, geranium, and croedium), and at other times, a sub-orthiculate group in the front (azalia) middle (olea,) or back parts (cassia). This is a very simple rule, easily recollected and applied, and every master and head gardener who approves of it, ought to insist on its being carried into execution in every case, whether in the open air or in hot-houses, where pots of plants are to be set down together; unless, indeed, it should, in the case of diseased plants, interfere with culture. The effect of this mode may be very well estimated by inspecting the hot-houses, or open air collections of pots
6209. The following directions respecting the particular plant-habitations of floriculture, are chiefly taken from Sweet's 'Botanical Cultivator' (of 1820), and Cushing's 'Exotic Gardener' (of 1814).

6210. Frame. Very little management is requisite for this department, as the plants kept in cold-frames are so hardy, that for seven or nine months of the year the sashes do not require to be put on. All that is requisite is to expose the plants to the air the whole of every day during winter when the weather is open, by drawing off the lights; to attend to watering them moderately, during winter in mild weather in the morning after sunrise, and in summer in the evening. Once a-year in spring each plant should be examined, and such changes made in the soil, size of the pot, head of the plant, roots, &c. as the experience of the gardener, the appearance of the plant, or the object desired by cultivating it may dictate. The routine culture of weeding, staking, picking off decayed flowers, leaves, &c. need not be insisted on; and the culture of particular species or even tribes cannot here be entered into. (See the Catalogue of Frame Plants, in Chap. VIII.)

6211. Green-house. The plants of this department, Sweet observes, only require protection from frost in winter. The more air they have given them when not frosty, the more healthy they will be. On a fine morning, the sooner air is admitted the better; but it is best to shut up pretty early in the afternoon, particularly if likely to be a cold night. No fire is required, except frost is expected in the night, or the house should be damp with continued wet weather; then a little fire is requisite to dry the house, as plants are more liable to be injured by damp than by cold. The plants should be looked over most days to see if any require water, which must only be given when quite dry, in the winter season: from nine to twelve o'clock in the morning is the best time for watering them; for, if watered in the afternoon, they are apt to be chilled at night, which makes their leaves look yellow and unhealthy. When the surface of the mould is green with moss, &c. the top should be taken off, and the surface moved with a flat stick, but not deep enough to disturb the roots; if a little fresh mould is wanting on any of them, it should be added. Always be careful to put the same kind of soil they are already grown in; for a different kind put on injures plants more than some cultivators are aware of.

6212. When the weather begins to get warm in spring, some air should be left all night to harden the plants before they are set out; a little must be left at first, and continue to increase it every night till they have full air, if the weather will allow of it. The time of setting them out in the open air depends entirely on the weather. Sometimes they may be put out with safety by the middle of May, in other seasons not till the latter end; but they had better stay in a little too long than be put out too soon. Calm cloudy weather is the best time for setting them out, when as sheltered a situation as possible should be chosen for them. The best time for shifting them in fresh pots is early in spring: some shift them before they are set out, and let them make fresh roots while in the green-house, which is a very good plan, particularly for young or tender plants. If any plants are too tall, and want cutting back, it should be done early in spring, as soon as they begin to grow; then they have time to recover themselves, and make good bushy plants by autumn.

6213. Cuttings require to be put in at various seasons, and in different situations. From Christmas to May may be considered the best time for cuttings in general; but some will require to be set out in at various seasons throughout the year, according to the state of the shoots. The best time for watering green-house plants in summer is as late as possible in the afternoon, then they have all the night to refresh them. If watered in the morning of a warm day, they will dry again almost immediately. Plants should not remain out too long in autumn, as they are liable to get too much wet, and the worms get in the pots. The middle of September should be the latest, but give them full air as long as the weather will permit. (Bot. Cultivator, 121.)

6214. Stove. The management of stove plants, according to the same author, whose experience and success are exceeded by none in the cultivation of exotics, depends a great deal on the kind of house in which they are grown; but there is little difficulty in growing them well, if the house can be kept up to a proper heat, and a sufficient quantity of air can be given when required. Close glazing is to be preferred;
either the lights should be leaded, or the laps stopped with putty, so that a sufficient quantity of air may be always given, and the house kept to a more regular heat. When the laps of the glass are left open, a great deal of air is admitted, which is often injurious, particularly on a cold windy night. The thermometer should never be allowed to be below 60° of Fahrenheit's scale; if it gets above 70° on a fine day, a little air may be given, which should be taken away early, and the house shut up warm; it then requires less fire to keep up the heat through the night. If the house is heated in the common way by flues, and the plants are plunged in tan, care must be taken not to give these too much bottom heat, as it will injure their roots, or too much water in winter, as it is apt to rot them. Particular caution is necessary for watering in winter, not to wet the tan, as it makes the worms very troublesome; they often destroy young plants by throwing the mould out of the pots; but a better way is the one now very generally adopted, viz. to do without plunging in tan. Some hot dung or tan may be still kept in the pit to throw up a little warmth, on which should be put a good thickness of sand or gravel for the pots to stand on, and the plants will thrive much better than when plunged in tan; it is also coming nearer to nature, which should be always studied in the cultivation of plants, both in soil and situation. In tropical countries it is the sun that heats the earth in which the plants grow, not the earth that heats the air; and the heat must be kept up in the stove accordingly. If the houses are heated by steam, no tan is required. The plants may be set on stages, or any way that is most convenient. Some of them may be planted out in the house, where they will grow in greater perfection, and flower and ripen fruit better than when confined in pots.

6215. To have plants look well they should be always kept clean and free from insects: if infested with any species of aphid, the house should be smoked with tobacco, which instantly destroys them. The red spiders are likewise a great pest to cultivators, but are also easily destroyed. One pound of sulphur vivum, mixed up in a pill of quick-time, and the flues brushed all over with it as a common whitewash, will destroy any quantity of them, and make the house look light and clean. The mealy bug is also troublesome if left to increase on the plants; but as soon as they appear they should be brushed off as well as the scaly insects: for, if left to increase, they will disfigure the plants, and be very difficult to get rid of. In fine weather the plants should be often sprinkled over with water from an engine, and the house shut up warm afterwards, which is a great means of keeping them clean and making them grow luxuriantly. Air should be given in the morning as early as possible, in fine weather, as it sweetens the house, and makes the plants healthy. It should also be taken away early in the afternoon, and the house shut up warm, that they may not be chilled by the night air.

6216. In potting plants, care should be taken to drain the pots well with broken potsherds or rough bits of turf; for nothing injures them more than letting them get sodden with too much wet. The best time to shift them in fresh pots is the spring, but some will require to be shifted again in autumn, to have them thrive well. The free-growing kinds cannot be well overpotted if there be plenty of room for them in the houses: they will thrive and flower better for being in large pots. Others that are more tender should be kept in as small pots as possible, that they may not get sodden, and lose their roots. (Bot. Cultivat. 1.)

6217. The reserve hot-houses of the ornamental garden may be divided into those for forcing hardy flowering plants and shrubs, and those for propagating exotics by seeds, cuttings, or otherwise.

6218. Herbaceous plants and flowering shrubs are generally forced in pits or low houses; and as soon as the flower-buds begin to expand, removed to the green-house or drawing-room, there to prolong the flowering season. The shrubs should be previously established in the pots, by being planted and plunged in the open reserve-garden a year beforehand: the autumn before forcing they should be thrown early into a state of rest, by covering them with canvas frames to exclude rain and sun, but so as to admit cold air. The operation should be commenced in July, and the plants removed to the hot pit in November or earlier. Herbaceous plants of most sorts, especially the fibrous-rooted kinds, may be taken up with bails, and planted in pots early in the autumn preceding the winter in which they are to be forced. Fusiform-rooted sorts earlier, as they do not rise so easily with bails; and the bulbous sorts, the bulbs being out of ground, may be planted in the end of autumn, plunged in the open ground, and covered with rotten tan or ashes, and taken up as wanted. It is of some consequence to remark, that the flowers should be pinched off both the shrubs and herbaceous plants, the summer preceding the forcing season, in order to communicate additional strength, and aid in throwing them more early into a state of rest. The bottom heat may either be from tan or dung, or a vault heated by flues or steam; but theformer we consider as most to be depended on. The temperature of the air of the house may at first setting in the plants be kept at 50° or 55°; and in a fortnight, raised 10 degrees higher. After that, it may be kept up to 60° or higher, admitting air during sunshine. The temperature of the pit should be kept as high as that of the air. Successional supplies should be kept for the first fortnight in a cooler house, or in the coolest part of the pit; or the temperature, on their admission, may be somewhat lowered. The other points of routine culture need not be entered into.

6219. The propagation-house requires to be kept at a much more moderate temperature both as to the atmosphere and the bottom heat than the forcing-pit or the principal stove. It need seldom exceed 60° in winter, and 65° in summer. Abundance of air must be given at certain seasons when damp and mouldiness begin to appear; and shading and watering, so as to produce a moist atmosphere, must be attended to in the summer season.
Floricultural Catalogue. — Herbaceous Plants.

6290. A floricultural catalogue, as copious as that which we have given of culinary plants and fruits, would greatly exceed our limits. Plants grown for ornament are so numerous, that we cannot particularise separately the culture of each individual species; but, with the exception of some of the more choice sorts, as the florists’ flowers, &c., must collect them in groups, and detail a mode of culture applicable to the whole group. We shall first commence with herbaceous flowers, and these we shall arrange as florists’, or select flowers, border-flowers, and herbaceous plants for particular purposes.

Sect. I. Florists’, or Select Flowers.

6291. Florists’ flowers are so called as being “flowers” by way of eminence, and because the principal sorts of them for a long time almost exclusively engaged the attention of the flower-gardener. The Dutch, in this, as in most other departments of gardening, were the first to bring it into notice, and more particularly by the great excellence to which they attained in the culture of florists’ bulbs. In the culture of that tribe, they still excel; but the fibrous-rooted flowers, as the carnation, auricula, &c.; and the tuberous-rooted kinds, as the dahlia, peony, &c. are brought to a higher degree of perfection in Britain than any where else. Ornamental flowers, like culinary vegetables which have been long and highly cultivated, acquire a magnitude, succulence, and conformation of parts which render them widely different from what they are in their natural state. This takes place both in double flowers, that is, when the petals of the corolla are increased in number, or by the transformation of other parts of the flower into petals; and also in single flowers, or those in which the petals do not exceed the common number. A flower so changed by cultivation, can no more be compared to the blossom of the same species in its wild state, than a headed cabbage or a broccoli can be compared to the wild cabbage of our sea-shores. Hence have been formed, by the common consent of florists, what are called canons of criticism, by which to estimate the properties of new varieties of established sorts of florists’ flowers. To the hyacinth, tulip, auricula, and a few other sorts, particular canons are adapted; but the merits of a number of other select flowers, double and single, are only to be judged of by general rules, such as fullness of floral leaves, roundness of outline, brilliancy and distinctness of color, &c. Under each species we shall give the established criterion, or canon, as far as generally agreed on. We shall take the plants of this section in the order of bulbous, tuberous, ramose, and fibrous rooted flowers.

6292. The bulb of the hyacinth is tunicated, the leaves broad and green, from the centre of which arises a scape, with a spike of flowers, pointing in all directions, and by which it is known, at first sight, from Hyacinthus nonscriptus, L. (Scilla nonscripta, W.), in which the scape is drooping, and the flowers all turned to one side. It is a native of the Levant, and abundant about Aleppo and Bagdad, where it flowers in February; here it flowers in March and April. It was cultivated by Gerrard in 1596; but had, doubtless, long before been improved by the Dutch, who have added greatly to the strength and beauty of the plant, and produced almost innumerable varieties.

6293. Varieties. Gerrard mentions the single and double blue, the purple, and the white. Parkinson, in 1629, enumerates eight sorts. Miller says, the Haerlem gardeners distinguish near 2000 sorts, and generally publish catalogues of them from year to year. At present, the taste for this flower being considerably abated, the Dutch and English catalogues contain only a few hundred sorts. Mason’s catalogue for 1830, contains three hundred sorts with names. These names are quite arbitrary, being given by the grower after himself or some public character; and therefore they are here omitted. They are arranged as double blues, whites, reds, and yellows, and single sorts of the same colors; the blues and reds are the most numerous; the yellow, those of which there is least variety. Only single hyacinths were at first cultivated; but about the beginning of the last century attention was paid to double flowers by Peter Voorhelm, whose first double flower was named Mery, and is now lost; but his third flower, the King of Great Britain, which is now looked upon as the oldest double hyacinth, was greatly preferred to all the flowers known, and the price of it was then above 1000 florins, or 100£. sterling. Up to the middle of last
**HYACINTH.**

The greatest attention was paid at Haerlem to raising new sorts of double flowers; and as much as 291/2 has been known to be given for a root: but, since the present time, and except where there are some sorts for which more than 10. are asked; the general price being from one to ten shillings a bulb for the varied sorts, and what are called the common mixtures are sold at from 2l. to 3. a hundred. A variety degenerates, under had treatment, in two or three years. The following are some of these presents:

6224. Criterion of a fine double hyacinth. (fig. 659. a) "The stem should be strong, tall, and erect, supporting numerous large bells, each suspended by a short and strong peduncle, or foot-stalk, in a horizontal position, so that the whole may have a compact, pyramidical form; or uppermost, perfectly double, i.e. well filled with broad, bold petals, appearing to the eye rather convex than flat or hollow; they should occupy about one half the length of the stem. The colors should be clear and bright, whether plain, red, white, or blue, or variously-intermixed and diversified; in the eye; the latter, it must be confessed, is added advantage, and lend a clear and elegant to this beautiful flower. Strong bright colors are, in general, preferred to such as are pale."

6225. Propagation. By seed for new varieties; and by offsets or bulbs for confirming approved sorts.

6226. By seed. "The seed should be saved from such sorts as have strong and straight stems, and a regular well-formed pyramid of bells, not perfectly single, but rather semi-double. It should not get the sun, as then it will not ripen in the proper period, and will appear yellowish on the outside, and will begin to open. The stem, with which the seed is connected, is then to be cut off, and placed in a dry, airy, cool situation, where it may remain undisturbed till the time of sowing, which is the latter end of October, or beginning of March; it should then be sown about half an inch below the surface of the soil, in a deep box, filled with good sound garden-mould, mixed with sand, or the hyacinth compost, which should be afterwards placed in a warm situation during winter. It will never require to be watered, or have any other attention paid to it than to keep it free from weeds and frost, till it has remained in this state two years; it must then, on the approach of winter, have an additional stratum of the compost placed upon it, about half an inch thick; and at the third year, in the month of July, the roots may be taken up, dried, and treated in the same manner as large bulbs or offsets: some of the roots will flower the fourth year, one half of them will flower the fifth year, and at the sixth year, the expectations of the cultivator will be realised or disappointed. He may think himself fortunate, if one half of the plants that first appeared, are in existence at this period; and if he can at last find one flower in five hundred deserving a name or place in a curious collection, he may be considered as assured of success; for he will probably be equalled, or bettered, than by thirty who have bestow'd equal attention on the subject." 

Maddock.)

6227. By offsets. These may be planted in the beginning of October, or soon after they have been separated from the parent bulbs. Plant them in an open place, in rows about fifteen inches deep, upon the common level, consisting of a sandy soil, pulverised, eighteen inches deep; the surface of the bed should be made rather convex or rounding, so as to throw off heavy rains; no further attention is necessary, except to stir the surface of the bed occasionally, to keep it free from weeds, and to preserve it from very severe frost. The proper time to take them up is about the third year; offsets, if preserved in health, will bloom weakly the second year; but by the third tolerably strong, and may afterwards be placed on the best bed.

6228. Choice of full-grown roots. "Such roots as have attained the age of four or five years, bloom stronger than any other; the larger roots afterwards decline, either by dividing into offsets, or diminishing in size and strength: but in Holland, owing to the peculiar circumstances of the soil, climate, situation, &c. the same bulb has been known to produce blossoms twelve or thirteen times, nor is it ever known to die merely with age."

6229. The bed in which they are to be planted should be situated in a rather dry and airy part of the garden; a southern aspect is to be preferred, sheltered on the north and east. When the situation is determined on, the dimensions of the bed should be marked out, and the soil entirely taken away to the depth of at least two feet; the earth in the bottom must then be dug up and pulverised, one spit or nine inches deeper, and the space above filled up with a compost consisting of one third coarse sea or river sand; one third fresh sound earth; one fourth rotten cow-dung, at least two years old; and earth of decayed leaves for the remainder. These ingredients should be well mixed and incorporated, and the bed should be filled up with the compost to about four inches above the level of the path on the south or front side, and ten inches on the north side, so as to form a regular slope or inclination towards the sun."

6230. In the winter. The florist of Nicholas Van Kampen and sons, florists at Haerlem (Haerlem 170), and New-York-Tyme, 1763), sandy earth is said to form the basis of the culture of the hyacinth. It ought to be of a bluish-grey or blackish-red color, not sharp, but rather handling smooth, a little greasy, and taking a pearl color when dry; and the water passing through it being transparent and with a delicate tinge of grey. It is said to be the best, if it is added to their compost, that of a delicate tinge of grey. "It is to make use of cow-dung, rotten leaves of trees, and tanners' bark; but the bark ought not to be taken fresh out of the pits, but laid up all the time at least, that it may be well rotten and consumed to one half: — Our method, then, of making compost for hyacinths is as follows: take six parts of grey sand; two sixths of well rotten cow-dung; one sixth of tanners' bark, quite rotten and reduced to earth; one sixth of tree-leaves, also well rotten. All these materials must be thrown into a heap, not more than three feet thick, so that the rays of the sun may have power to penetrate through it, and warm the bottom for the heat of the sun is used in the mixture, to the north of the heap, it ought to be carefully turned, and the bottom thrown to the top, that all parts of it may partake of the benign influence of the sun and elements; this is essential; and this turning must be continued for twelve months, taking care not to sift the compost, because, in passing through the sieve, it is apt to run into lumps, which would be of dangerous consequence."

Quoted in "Wald, in Hort. Tour," p. 525.

6231. In St. Simon's work, entitled Des Jardinieres (Amst. 1768, 4to.), in which the Dutch mode of cultivating the hyacinth is fully presented, the compost used at Haerlem is said to be rotten cow-dung, rotten leaves, the leavings of elm, lime, and birch are preferred to those of oak, chestnut, walnut, beech, pine, &c. which do not rot so readily. The cow-dung is collected in winter from cattle, staled upon dry food, without any mixture of straw or other litter. The leaves, when decayed and fit for use, are thus mixed with the other materials. First, they are spread in thin layers on a heap, till they reach a depth of six to ten inches thick. These layers are repeatedly turned till the heap is six or seven feet high, a layer of dung being uppermost, sprinkled over with a little sand to prevent the too powerful action of the sun upon it. After the heap has lain thus for six months or more, it is mixed, and then stored some weeks in a cool, damp situation, before it is carried into the flowering beds. This compost retains its qualities about six or seven years; but the Dutch avoid setting hyacinths in it two years successively; in the alternate years they plant tulips, jonquils, narcissuses, crocuses, irises, &c. in the same beds; nor do they venture to set hyacinths in the compost the first season, when the fresh manure is put in.

6232. Planting. This should take place "from the middle of October to the middle of November; if it is done earlier the plants will appear above ground in the middle of winter; or if it is deferred later, the roots will be weakened by their natural tendency to vegetate. On planting the roots, the surface of the bed should be covered with a little fresh sandy earth, about one inch thick, raked perfectly smooth
and even, and have the exact situation for every bulb marked upon it (fig. 591), regularly mingling the colors of red, blue, and white; the yellow being classed with the latter. The depth of the surface of the earth may be four feet, and six rows may be placed across it at eight inches asunder, the two outside rows being each four inches from the sides of the bed; consequently the space between the centre of each bulb will be about nine inches and a quarter. On planting hyacinths, a little clean sand should be placed underneath, and likewise upon the roots, to prevent the earth adhering too closely to them; while then to be covered with sound fresh sandy earth, from three to four inches deep, according to the size of the bulb; when this is completed, the bed will be about eight inches high above the level of the walk on the south or front side, and about fourteen inches on the north; it will look neater and have a better effect, if it is supported on each side with a strong frame of thick boards or brickwork.

6233. The Dutch Florist directs, "After a place has been pitched on for planting the flowers; the natural earth must be dug out to the depth of three feet, and the bottom covered with a stratum of cow-dung half a foot thick; which must be beaten and trod down till it be very firm and compact like a hard crust, so as to prevent any communication with the sub-soil. Then the hole is to be filled up with compost, six inches above the firm earth, and the flowers planted as near above them as possible: the plants should be laid into the designed bed about a month before the roots are planted; for if it be put in later, the earth might settle while the roots are in it, which would lay them too deep. The proper season for putting in the bulbs is October and November. They ought to be set at the depth of four or five inches; but early flowering varieties may be one inch deeper, which will bring the flowers into the same time as with the others." (O’Reilly, in Hort. Farm. Set. 4.)

6234. Culture. "In order to preserve it from very heavy rains or severe frosts, it should be hooped over, and mats or canvass should be placed at hand ready to cover the bed on such emergencies; but it will not be necessary to defend it from moderate rains or slight frosts; the action and influence of the air, which ought to be avoided as much as possible: it was even better to run the hazard of incurring a slight injury by the omission of covering on some occasions, than to overdo it to the certain detriment of the plants. If frost is permitted to penetrate so far into the soil as to reach the bulbs, especially about the time that the plants are about to appear above ground, it will immediately injure some of them to shoot forth or discharge their stems and blossoms; but if the roots become entirely frozen through, they are in danger of being destroyed. The earlier sorts will begin to open and show color about the beginning of April; it will be proper to screen such from the detrimental effects of the sun during this period, if not prevented, would bleach and tan their colors, particularly the reds and deep blues; but if they are properly defended from it, their colors will be preserved, and they will, in some measure, be kept back, so as to be in full bloom with the later sorts, especially if the roots of the early sorts have been planted about an inch deeper than the rest: it is a very favorable object to the gardeners to support the stems as they advance so high; for, this purpose, small sticks or wires, painted green, should be forced into the ground, immediately behind the rhizomes, either in an erect position or leaning a little backwards, to which the stems are to be rather loosely tied with small pieces of green worsted, as soon as they begin to bend, or are in danger of breaking with the weight of the corolla or bell: this operation must be repeated as they advance in height, for it is impossible to do it at one time so as to answer the purpose. When the greater part of the bed appears in color, a covering, or awning, should be erected over it and the path in front: the awning should consist of a strong frame of wood, ten feet high in the centre, and seven feet at the sides, covered with fish or Scotch sheeting, or Russia duck, which will effectually keep out rain, and admit a great degree of light; it should come down close to the bed on the north side, in order to preserve it from cold winds, which are prejudicial to the bloom. The covering (fig. 594) should be so constructed of timbers (or rafter poles, b), as to be easily and expeditiously rolled up, or let down, as occasion requires, to afford the plants the full benefit of light and air, at all favorable opportunities, that is to say, when the air is mild and light clouds intervene, so as to blot the sun’s ray. This sometimes, and, indeed, often happens to be the case from seven to nine o’clock in the morning, and from four to six in the evening, at which time, so much more power is less power than in the middle of the day. A bed of hyacinths never requires to be watered at any period; the rains that happen after planting are generally more than sufficient both for the roots and the bloom; and after the bloom is over they are rather prejudicial than otherwise, except when very moderate. Although covering in the manner described prevents and exhibits the bloom to the greatest advantage, yet evidently they have a tendency to weaken and injure the bulbs, and ought not, therefore, to be continued more than two or three weeks at most; but as soon as the general blooming begins, the beds should be immediately exposed to the open air, and the mats and hoops should be replaced as before, to keep off heavy rains.”

6235. Taking up the bulbs. "It is the practice in Holland, to take up the bulbs about three weeks or a month after bloom, in the following manner: As soon as the plants begin to put on a yellowish decayed appearance, and the roots at the top of the stem and diagonally to the third of half an inch of the bulbs, but leave the fibres, &c. attached to it; they then place the bulbs again on the same bed, with their points towards the north, and cover them about half an inch deep, with dry earth or sand, in the form of a ridge, or little cone, over each; in this state they remain about three weeks longer, and dry or ripen a little; this air admitted as possible; the bed is afterwards hooped over, and too hot a sun; at the expiration of this period the bulbs are taken up, and their fibres, which are become nearly dry, gently rubbed off; they are then placed in a dry room for a few days, and are afterwards cleaned of that adherent or loose skin and dust taken off, with such effects as may be easily separated. When this dressing is finished, the bulbs are wrapped up in separate pieces of paper, or buried in dry sand, where they remain until the return of the season for planting. Another, and less troublesome, mode of treatment after bloom, though perhaps more hazardous, is to keep the bed airy, and rather dry, till the stems and foliage appear nearly dried up or consumed; this will seldom happen to be the case in less than two months; the bulbs are then to be taken up, cleaned from the fibres, soil, &c. preserved in sand or papers as before directed.”

Part III.
6236. Von Kampen and son say, "We take up the roots as soon as the leaves begin to wither, that is, when their plants begin to turn yellow. We then break off the stems an inch above the bulbs, which we afterwards cover with earth, in which they are to lie till the grass moisture be dried up by the warmth of the sun. We make a little heap of earth, and place the roots in it, bottom downwards as they grew; and the heap is covered with another heap of two or three inches. When the heap has lain one or two weeks, they are to be taken out in fair weather, and laid on a board in the sun for an hour, after which, they are to be cleared of the earth and offsets about them, taking great care not to give the least bruise or wound." (Quot. by Neill, in Hort. Tour, 583.)

6237. Herbert says, "The bulbs should be placed in an airy store-room, and not suffered to touch each other; a moveable stage of open lattice-work, furnished with drawers, may be used, and the utmost attention should be paid to ventilation." A French florist, Baudry, is said (Caled. Hort. Mem. iv. 76.) to have lost annually a number of his hyacinth-bulbs through dampness until he adopted the expedient of placing them in the store-room with the base of the bulb upwards. Drawers of lattice-work would effect the same object.

6238. Diseases. Hyacinths are subject to various diseases, arising from different causes; that destitute of a formal name, caused by the apple reminding of the ring-sickness, is of all others the most dangerous and most difficult to cure; in short, the only effectual remedy is to cut out the diseased part, till no brownness, yellowness, or other symptom of destemper remains. The sound part will survive the operation, if it consist of no more than the outside tunic of the bulb, without any heart; but it will, in such case, only be for a very few weeks, and will never recover; but so soon as the operation is performed, the wounded part should be exposed to the sun, till it becomes dry, to prevent mouldiness, and it will be best to replant it in some dry situation soon after." "The Dutch," Herbert observes, "are much troubled with this disease; the cause of which appears to be a fungus, the spawn of which is nurtured in the cow-dung. The only remedy is the removal of the distempered bulb, and the compost that was in contact with it."

6239. Duration of bulbs. "The hyacinth delights in a sandy soil and saline atmosphere; of consequence it succeeds best on the sea-coast, or in situations very near the sea. In more inland parts, it will generally be found necessary to procure an annual reinforcement of fresh imported bulbs, in order to make good or supply the deficiencies arising from the loss, or impaired health and strength of many of those that have bloomed on the best bed preceding spring. Those who are well acquainted with the hyacinth, always procure the thickest bulb in twos or threes, notwithstanding they may be discoloured at the time of planting; such generally have a corps de réserve, in narrow deep pots, which, at the commencement of bloom, they plunge or sink into the bed, wherever a vacancy, or weak sickly plant makes its appearance; by which means the identity and regularity of the bed is preserved, without any visible defect or alteration." Herbert says, "My own experience enables me to say, that the nurseries in the neighborhood of London may produce hyacinth-bulbs equal, if not superior, to those imported from Holland; though, perhaps, with greater loss from disease, owing to his not being able to procure the dung of certain species of cows," (Hort. Mem. iv. 186.)

6240. Forcing the hyacinth. Plant the roots in narrow deep pots, filled with sandy loam, in October; plunge them in and cover them with old bark-leaves or sand; they will soon throw down roots, and a part may sprout; only in November, be plunged in bottom heat, which will come into bloom by Christmas, and successional supplies can be taken from the store planted in October, and a bulb thus kept up till they flower in the open air. The best sorts to force are the single blues and reds.

6241. Blowing hyacinths in water-glasses. Blue or dark-colored glasses are more favorable to the propagation of the light ones, light being injurious to all roots. The bulbs to be blown in the glasses should be planted in October, in earth in which they push their fibres more regularly, and taken up as wanted, washed from the earth, and placed in the blowing-glass; the glasses may be kept in a warm room or in a stove. The water should be soft, and the glass so full that it may rise a fourth of an inch on the bulb, and if this becomes fetid, it should be renewed.

6242. The bulb of the tulip is solid, and sends up an upright stem from twelve to eighteen inches high, with glaucous leaves, and a large erect flower, the petals in its wild state having a black base. It is a native of the Levant. It is common in Syria, and is supposed by some to be the "lily of the field," referred to in Christ's address from the mount; though Sir J. E. Smith thinks the amaryllis lutea is there meant. In Persia, where the tulip is abundant, it is considered as the emblem of perfect lovers. "When a young man," says Chardin, "presents one to his mistress, he gives her to understand, by the general color of the flower, that his body is on fire with her beauty, and by the black base of it, that his heart is burned to a coal." According to Gesner, the tulip was brought to England by James Garnet, in 1577, having been introduced, according to Hakluyt, from Vienna. Towards the middle of the 17th century, the tulip became the object of considerable trade in the Netherlands; it rose to its greatest height in 1634, and the three following years. According to Beckmann (History of Inventions, art. Tulip), for one root of a variety called the Viceroy, articles to the value of 2200 florins were agreed to be delivered. The Semper Augustus has been sold for 2000 florins; one person agreed to give 4600 florins (about 460L.), with a new carriage, two horses, and complete harness; and another agreed to give twelve acres of land for a single root. The trade was generally followed for a time, and having no foundation in real utility, like the Mississippi and South Sea schemes, it was a mere gambling business, and rightly named Tulipomania. John Barclay, the celebrated author of the romance of Argenis, is said to have had this mania to such an excess, that he placed two mastiffs as
sentinels in his garden. This was between 1600 and 1621, when he lived at Rome, in an ill aired and unhospitable habitation; in which, however, he chose rather to continue than abandon his favorite flowers. (Oblatiner's Biog. Dict.) The taste for tulips in England was at its greatest height about the end of the 17th and beginning of the 18th century; about the year 1730 or 40, it had declined and given way to the taste for botany, and new plants from America and other foreign countries. The tulip, however, is still much cultivated both in Holland and England, near large towns, though in the latter country there are now very few good collections in the private gardens of the higher classes. Like the auricula and some other flowers, it is more the flower of the tradesman and operative manufacturer than of the botanist or man of fortune.

6244. The names of the different varieties, classed under these heads, being perfectly arbitrary, and constantly changing, their insertion here could be of no use. (See the Annual Catalogues of Bulbous Roots, published by the nurserymen and florists.) What are called breeders are procured from seed, and consist of one plain color on a white or yellow bottom. The seeds are large and rather fleshy. These are divided into three classes, variagated, and variegated tulips. The time that elapses before they break various colors, and are the first to bloom. These raise new varieties of tulips from seed must be possessed of an ample fund of patience and perseverance. The name of the dwarf kind, florists, is that of the Van Tholl, is a distinct species, T. tenuiflora. Formerly there were several varieties of early dwarf kinds.

6245. Criterion of a fine variegated late tulip. The stem should be strong, elastic, and erect, and about thirty inches above the surface of the bed. The flower should be large, and its cup to embrace the greatest part of the stem, forming almost a perfect cup, with a round bottom, rather wide at the top. The three exterior petals should be rather larger than the three inner ones, and broader at their base. All the petals should have perfect entire edges, free from the notch or serrature; the top of each should be broad and well rounded and the ground color, white or yellow, and the various rich-colored stripes, which are the principal ornament of a fine tulip should be regular, bold, and distinct, on the margin, and terminate in fine broken points, elegantly feathered or penciled. The centre of each leaf, or petal, should contain one or more bold blotches, or stripes, intermixed with small portions of the original or breeder color, abruptly changed in color, or irregular obtuse points. Some florists are of the opinion that the central stripes, or blotches, do not contribute to the beauty and elegance of the tulip, unless confined to a narrow stripe, exactly down the center, and that they should be perfectly free from any remainder of the original or breeder color. Such an approach is not always, however, when they have a regular narrow feathering at the edge; but the greatest connoisseurs in this flower unanimously agree, that it denotes superior merit, when the tulip abounds with rich coloring, distributed in a distinct and regular manner throughout the flower, except in the bottom of the cup, and that the bottom should be distinctly different, or an entire change, in order to constitute a perfect flower.

6246. Propagation. By seed for new varieties, and by offsets for continuing approved sorts.

6247. By seed. Select such breeders as have tall strong stems, with large well-formed cups, erect in the bottom, and save seed from the finest of these. Yes is the seed of such kinds produces nothing but poor weak breeders of no value. "It should remain growing on the stem till the pericarpium becomes of a brownish color, and begins to open; it is then sufficiently ripe, and should be cut off, with six or eight inches of the stem, and treated afterwards, in all respects, agreeable to the directions given for the management of hyacinth-seed. Some of the seedlings will bloom by the fourth or fifth, and most, if not all, by the seventh year."

6248. By offsets. These should be planted after they are separated from the parent bulb, in beds of fresh sandy loam, with a little rotten cow-dung placed seven to twelve inches below the surface, in a dry airy situation, from two to four years, according to the size of the roots. The beds should be raised six or eight inches above the alleys, formed rather convex on the surface, and may be provided with hoops and mats, to be used to guard them, as occasion may require, from heavy rains and severe frosts.

6249. Bulbs of the Dutch tulips have not lost their buoyancy, nor is there anything as hard as the Dutch tulip for the root end, and are full, solid, and rather pointed at the other. Just before planting, strip off the brown skin so as to leave the root perfectly bare and white, performing the operation with great care, to avoid bruising or wounding the root, especially at the lower end, where the fibers are formed, which is, at the season of planting, extremely tenacious.

6250. Soil and situation. "The situation for the best bed should be in an open airy part of the garden; when that is upon the ground should be marked out, agreeable to its intended dimensions, and the soil taken out twenty inches deep; the bottom is then to be filled up with rich earth, manure, and the like, and upon this to be placed a stratum of six to ten-year-old rotten cow-dung, and earth of the above description, about one half of each, well mixed together, twelve inches thick; and again, upon this to be placed another stratum of the same kind of earth as that of the bottom; this is only to be two inches thick, and the like, to the manner of the cup will be, to give it a smooth surface as it will be formed about the 30th of October, i.e., a week or two before planting, to give the bed time to settle; at the expiration of two weeks, the earth will have subsided, so as to be about two inches higher than the circumference of the bulb, but if heavy rains intervene between this preparation, and the bed subsequent to planting, the earth must be rendered too compact and adhesive, by a redundancy of moisture for the fibres to pass freely through it, which ought to be avoided." Hogg recommends a fresh, rich, loamy soil, of rather a sappy nature, which should be dug twelve months at least before it is used, and a small portion of well rotted dung must be added. He says, an old-fashinewed tulip-grower assured him, that the best compost he had ever hit on was: "three fourths rich yellow loam; one fourth leaf-mould; one sixth two-year-old horse-dung; and
one Eighth sea-sand, well incorporated, and laid in a bed, or stratum, for the plants, two feet deep." (Tr. on the Carnation, Acricula, Tulip, &c. 142.)

6251. Planting. The most proper time is from the end of October to the tenth of November. On the day made choice of for planting, rake the surface of the bed smooth and even, still preserving its convexity, and mark the exact situation for every root upon it. The proper distance between each root is seven inches from centre to centre; and if the rows are seven inches asunder, the roots will form squares of similar diameter on all parts of the bed. A bed consisting of seven rows makes the noblest appearance, when it is of sufficient length, with a path round it about two and a half or three feet wide; but where the number of roots is small five rows may suffice, and the path, in that case, may either extend quite round the bed, or only on one side, at pleasure. If, therefore, the bed consists of seven rows, it should consequently be fifty inches wide, which will allow a space of four inches between the outside rows and the sides of the bed; but if the bed contains only five rows, it will only require to be three feet wide, to give the roots similar distances. Having sprinkled a little clean sand where the roots are to be set, place them with great exactness and add some very sandy earth, so as to completely envelope each root in a little cone of it; then cover the whole very carefully with strong, sound, fresh loam, about four inches thick at the middle of the bed, gradually decreasing as it approaches the sides, where it should be about three inches thick; thus will the convexity of the surface be increased in a proper degree, and the roots will be covered with soil, to a depth proportionate to their size and strength; the largest and strongest having been placed in the centre rows, and the smaller and weaker on those of the outside. No tulip-root, whatever may be its size or strength, should be planted more than four inches deep from the upper side of the root; nor should any blooming root be planted less than two and a half or three inches deep, however small it may be. The soil made use of for covering the bulbs should be frequently turned over, and thoroughly exposed to the sun and air, some time before it is made use of, that it may be rendered perfectly sweet and free from the acid quality that most soils are subject to, when taken considerably below the surface. But if the bed is only to contain five rows, with a path in the front, and none behind, then it will be proper to plant the smallest and lowest growing roots in the front, next the path, and so gradually to increase in the size of the roots to the fifth or last row, which should contain the strongest and largest of all; when the roots are properly covered with soil, as before directed, the surface of the bed will slope one way, forming an inclined plane: it will be necessary to support its highest side at least with boards or brick-work, otherwise the earth would be liable to crumble down and leave the roots bare or too shallow.

The following section elaborates on the cultural management of tulips, focusing on soil characteristics, timing of planting, and the importance of proper placement and depth to ensure healthy growth. The text advises on the adecuacy of soil composition, ensuring that it is suitable for tulip planting, with considerations for the wetness or dryness of the soil and the need for proper drainage. It also stresses the importance of limiting dormancy periods and ensuring that plants are adequately protected from damage. The sections on planting and cultural management continue, emphasizing the need for careful handling of bulbs and the strategic placement of plants to optimize growth and appearance. The document is an instructional guide for tulip cultivation, intended to provide gardeners with a comprehensive understanding of the requirements and practices necessary for successful blooming.
several days, without requiring to be changed, and will make a tolerable appearance. About a week or
ten days after full bloom, when the petals of many begin to drop off, the awning should be taken down,
together with the frame, boards, &c. that surround the bed; and the mats and hoops may be replaced as
before, to prevent the loss of excess of rain, as the case may require; and as the leaves or petals of any fail, the
seed-velvet of such should be immediately removed close to the stem; for if suffered to remain on the
plant, it will procrastinate the period of its maturity, and weaken the root considerably. The bed may
remain in this state about a fortnight longer, by which time the grass, or foliage, will become of a yellow,
slightly-brown, and two or three inches of the top of the stem will wither, dry up, and become purplish: this
denotes the critical period to take up the roots, because if done earlier, they will be weak and spongy,
and if deferred later, their juices will become gross; this will be manifest at the succeeding bloom, by too
great a redundancy of colofitic matter in the petals, and the flowers being what is generally termed foul."

6233. Taking up the roots. Dig them up carefully, and place them under cover, in a dry, airy, shaded
situation. Here they may remain untouched till August or September following. "Then it is proper to
take off their loose skins, fibres, and such offsets as are easily separated; observing not to leave the roots
too bare, because the action of the air upon such would have a tendency to weaken and injure them, by
drying up part of their juices; the last brown skin, which is so intimately connected with the root, should
remain on it till the time of planting." "

6234. Diseases. The tulip is harder, and less liable to disease and injury from weather, than most sorts
of flowers; it is sometimes attacked by grubs and wire-worms at the root early in spring, and then the
best mode is to remove the plant and a portion of the soil, replacing the former from the reserve or
offset-buds.

6235. Forcing the tulip in pots or water-glasses. The early dwarf sorts are well adapted for this purpose,
even the Due Van Tholl. They may be treated as in forcing the hyacinth.

Subsect. 3. Ranunculus. — Ranunculus Asiaticus, L. (Mill. Tc. 2. t. 216.) Poly.
Polyg. L. and Ranunculaceae, J. Renouncle, Fr.; Ranunkel, Ger.; and Ranun-
colo, Ital. (fig. 593.)

6256. The ranunculus from a fasciculus of small tubers sends up several bipartite
leaves, and an erect branched stem with a terminating flower variously colored. It is a
native of the Levant, and was cultivated by Gerrard in 1596. Though rather a tender
plant, innumerable and highly beautiful double-flowered varieties have been raised from
seed, chiefly by the English florists, from the middle to the latter end of last century.

6257. Varieties. Only double ranunculuses are held in esteem: of these, Parkinson,
in 1629, enumerates eight; and Ray, in 1665, twenty sorts. Justice, in 1764, divides
ranunculuses into Turkey and Persian; of the former he enumerates eighteen sorts, and
of the latter a hundred. What he calls the Turkey ranunculus is only a variety or sub-
species with a very dark flower, which Miller also considered as a species, and named it
R. sanguineus. Maddock, in 1799, had upwards of eight hundred sorts. Mason’s
catalogue for 1820 contains about four hundred names. “There are more varieties of
ranunculuses,” Maddock observes, “than of any other flower;” but as their names are
arbitrary, it would be of little use to enumerate them here. A variety will last from
twenty to twenty-five years.

6258. Criterion of a fine double ranunculus. (fig. 593. a) “The stem should be
strong, straight, and from eight to twelve inches high, supporting a large well formed
blossom, or corolla, at least two inches in diameter, consisting of numerous petals, the largest at the outside,
and gradually diminishing in size as they approach the centre of the flower, which should be well filled
up with them. The blossom should be of a hemi-

6259. Propagation. By seed, for new varieties, and by offset-tubers, or dividing the
tubers for continuing approved sorts.

6260. By seed. The seed of the ranunculus, Maddock observes, in no instance ever produces two
flowers thus near the same size, or the same colour. It should be saved from such semi-double flowers as have tall
strong stems, a considerable number of large well formed petals, and rich good colors, chiefly preferring
the darker, but not to the exclusion of the lighter colored, when their properties answer the foregoing
description. The seed should remain on the plant till it has lost its verdure, and becomes brown and
dry; it may then be cut off, and spread abroad upon paper in the seed-room, exposed to the sun, that
every degree of humidity may be excluded from it; in which state it should be put into a bag, and pre-
served in a warm dry place.

[January is the proper time to sow the seed; and in order to prepare it, it must be separated from
the stalks to which it is connected, in the following manner, viz. in the first place, it should be taken out
of the bag, and spread thin upon a sheet of paper or tea-tray, &c. and placed before a moderate fire, till
it is just warm, and no more; the seed will then easily scrape off, by means of a penknife; but great
care must be taken to avoid scraping it off in lumps, or suffering any pieces of the stalk, dried petals of]
the flower, or other extraneous matter to be mixed with it, which would create a mouldiness when sown, of very destructive consequence: when the seed is scraped in a proper manner, it will have much of the appearance of clean coarse bran, with a little brown or purple speck in the centre of each cuticle, which is the kernel. When the seed is thus prepared, it should be sown in a shallow frame, provided with sashes; the earth should be barely covered to the touch, the seed being carefully distributed, and the frames kept covered; the seed should not be watered. When the pit is filled up again with the frozen heaps of earth, it should remain till the whole mass has thawed and been pulverized; and, if so, the seed should not be watered, but be made perfectly smooth and even, and the seed sown upon it with the utmost regularity, in such quantity as nearly to cover it; the glasses should be placed over it immediately, and the frame kept closely covered with them, for two or three days, till the seed begins to swell and soften; a little light earth, or other suitable soil, should be raked upon it. The glasses should be repeated once or twice a-week, till the greater part of the seed disappears: it is proper to remark in this place, that such seeds as happen to be covered deeper than the thickness of a half-crown piece, will never vegetate, and must of course, inevitably perish.

2623. After the plants are all up, and their two interior leaves appear, more air must be given, by having hurdles or lattice-work substituted for the glasses; waterings must be regularly continued, in the manner before described, when the long continuance of dry weather renders it necessary: but fine warm showers of rain are always preferable, when they happen in due time. This kind of management is to be continued till the roots are matured, and fit to take up, which is known by the foliage becoming perfectly brown, dry, and nearly consumed.

2624. The speediest and safest method of taking up these small roots is to pare off the earth, three inches deep, with a trowel or knife, having previously carefully exposed the dried and extraneous matter that may be found upon it. The earth and roots, thus collected, are to be thrown into a fine brass-wire, that will not permit the smallest roots to pass through it; the sieve is then to be worked in a large vessel or tub, nearly filled with water; the earthy part will, in consequence, be dissolved and float to the top, and the roots will be left in the tub. The roots may easily be separated from the stones, &c which are mixed with them. The upper rim of the sieve must be at all times, be held above the surface of the water, otherwise some of the smallest roots will be lost, as they are frequently found floating on the surface, till they receive a sufficient quantity of water to swell them.

2625. By offsets. Unlike the offsets of the hyacinth and tulip, those of the ranunculus generally attain perfection in the season of their formation on the parent plant, and are therefore fit to be planted as full-grown tubers the same season in which they are removed. The offsets, which are unfit to bloom the following year, may be planted in a bed prepared as to be directed for the full-sized roots.

2626. By dividing the tubers. "In minutely examining the crown of a ranunculus-root, several protuberances would be found; from each of which a shoot will arise, and the root may therefore be divided by a sharp knife into as many parts as there are protuberances; and thus the danger of losing any rare variety is much diminished. These sections will not bloom till the second year." (Hort. Trans. iv. 380.)

2627. Choice of full-grown roots. Select such as are sound and full in every part, and have plum and prominent buds.

2628. Soil and situation. According to Maddock, a fresh, strong, rich, loamy soil is preferable to all others. Hogg recommends fresh loam, with a considerable portion of rotten horse or cow dung. The Rev. W. Williamson (Hort. Trans. iv. 183) uses a stiff clayey loam with a fourth part of rotten dung.

2629. By planting. "This may be done either before or after winter: if the soil and situation is remarkably cold and wet, it will be better to defer planting till the middle of the year, or beginning of February; but in other situations, the latter end of October or beginning of November is to be preferred, as the roots will have more time to vegetate and form themselves, and will in consequence bloom rather stronger, though only a few days earlier than those later planted. A bed, consisting of the variety called the scarlet-turbaned, produces the most brilliant effect; if planted, as the full-sized roots, they will bloom together; they are harder than any other ranunculuses, but may, in other respects, be treated in the same manner. The surface of the bed should be raked perfectly even and flat, and the roots planted in rows, at the distance of about five inches from each other to a plant, and the trench or furrow, in which the roots are placed, should be about six inches wide. This is done in order for the reception of the roots: there should be a little clean coarse sand sprinkled into the trench, and the roots should be placed with their claws downwards, from three to four inches asunder, according to their size; when the trench has received its roots, it should be carefully filled up level with the earth that was taken out, so as to cover the root exactly one inch and a half deep, which is the only true depth to procure a good bloom: it is pointed out by nature in a singular manner; for when these roots have been planted too shallow or too deep, in either case, a second root is formed at the proper depth, by which the plant is placed markedly to appear, and to broaden the ground or frame it, but never again after the tenth of February; and he frequently plants the roots in the same place for several years successively." (Hort. Trans. iv. 576.)

2620. Future culture and management. Ranunculus-roots will remain several days in the ground after planting, before they begin to vegetate; during this period, they become very much swelled, by imbibing the moisture of the soil, and are, in this state, extremely susceptible of injury from frost, much more so than when vegetation has actually taken place. As soon as the bed is planted, a sufficient quantity of barley or oat straw should be placed near it, in case of frost, it may perhaps be

3 H 2
necessary, during a very severe winter, to cover the bed in this manner ten or fifteen inches thick; but the straw should be taken off at all favorable times: for the effects of covering too much or too long are as destructive as the reverse, especially before the roots have begun to vegetate, because they are then more liable to become mouldy than at any other period, than which nothing can be more prejudicial. Early in the spring, when the plants make their appearance above ground, so as to render the rows easily discernible, the surface of the earth between each row should be trodden or beaten, so as to make it firm and compact; and if the soil is compressed with the fingers, quite close to the plants, it will keep out cold drying winds, and prove beneficial. It is advisable to make choice of a fine dry day, soon after rain, whilst the ground is still moist, to perform the above operation: when it is finished, a little long straw should be placed between each row, to preserve the surface of the soil cool and moist, till the foliage of the plants is sufficiently grown and expanded, to afford it shade without further assistance.

6271. Water. April showers, and frequent rains in May, are essentially necessary to the growth and vigor of the plants: if these fail, soft water must be administered in sufficient quantity to keep the rows or plots from becoming dry, by means of a common watering-pot, with a long tube or spout, held low, so as not to wash the earth into holes; for it is better to avoid watering the plants themselves, as it may chill them too much, and stagnate their juices. The consequences of omitting to water when necessary are these, viz. the plants will make little progress; the blossom-buds of the broad-leaved sorts will not open at all; the grass, or foliage, will put on a sickly yellowish appearance, from which it will never recover during the season; and, lastly, the roots will, when taken up, be small and lean. But such kind of waterings, however necessary, are by no means so salutary to these, or any other flowers, as fine, warm, rainy days, in which they can be equally dispens'd, nor are the plants naturally disposed to receive any when the atmosphere is dry, because their pores and fibres are contracted, and they are, as it were, in the expectation of dry weather. Since it is evident that artificial waterings are, in all respects, so much inferior to natural, it is better to wait a day or two, in hopes of a change of weather, rather than to hasty take them, if it be really possible that although the plants may appear to suffer for the moment, by the omission; for if such a change should fortunately take place, they will receive infinitely more benefit from it than if both themselves and the soil are already saturated, or replenished, with moisture.

6272. Shading. The weather in May is sometimes very clear and hot; the plants ought to be shaded at such times by means of loft-y hoops and mats, or some better contrivance, that will admit light and air freely; a frame and covering, similar to that for hyacinths, would answer best, if expense and trouble were not to be considered: it will, however, be absolutely necessary to shade them, in some manner, during the period of bloom, otherwise they will continue but a very short time, especially the dark rich-colored sorts; for, in proportion as their colors approach to black, is the injury they will receive from the rays of the sun, if permitted to shine upon them in full force; some of the very darkest cannot stand it one hour without being entirely spoiled. The light colored sorts will bear the sun's rays much better, reflecting them to proportion as they approach to white; green is the only color that reflects and absorbs the rays of light in equal proportion, and is more predominant in the vegetable kingdom than any other. After the bloom is over, watering is no longer necessary, but shading, in the middle of hot days, is still very beneficial to the plants: it tends to prolong their vegetation, and the size and substance of the roots are thereby increased.

6273. Taking up the roots. By the end of June, or soon after, the greater part of the plants will appear brown and dry: vegetation has then ceased, and it is the exact time to take up the roots, because if they are suffered to remain in the ground till rainy weather ensues, they will begin to shoot afresh, and thereby sustain considerable injury. When the roots are taken up, their stems, &c. should be cut off close, and they should be placed in a shady airy room, or situation, to dry gradually; but before this is perfectly accomplished, it will be proper to clean and separate them, because, when quite dried, they become very hard and brittle, and there is great danger of breaking off their claws: some may be separated into many complets; they can neither be so closely connected, as on a superficial observation, to cut off the appearance of only one large root. Nothing more remains to be done, till the return of the planting season, except to stow the sorts separately in bags or boxes, for the sake of convenience, in a dry room, in which state it is possible to keep them for two or three years without perishing, although it evidently hurts them to weaken them and injure them: there have been instances known of the ranunculus-roots surviving till the fifth or sixth year; they were, however, rendered extremely weak, nor could any but very strong roots retain their vegetative powers for so long a period. Williamson takes up the roots immediately after the color of the foliage begins to fade.

6274. Forcing. The ranunculus may be forced, but loses much of its strength of stem and brilliancy of color.

6275. There are two species of anemone cultivated as florists' flowers, under the common name of anemone: the A. coronaria, L., or poppy-anemone (Bot. Mag. 841. (fig. 594. a), a native of the Levant, and introduced in 1596; and the A. hortensis, the star or broad-leaved anemone (b), a native of Italy, and introduced from Holland in 1597. The anemone has been cultivated from as early a period as the tulip, and many fine double varieties produced both by the Dutch and British. The single and semi-double flowers are nearly as high estimation as the double ones.

6276. Varieties. These are numerous, but few of them are named. Parkinson, in 1629, enumerates thirty sorts of single narrow-leaved anemones, and nearly as many double and single of the broad-leaved sort. Mason's catalogue for 1820 contains seventy-five sorts. A variety will last for twelve or fifteen years.
6277. Criterion of a fine double anemone. (fig. 595.) “The stem should be strong, elastic, and erect, not less than nine inches high. The blossom, or corolla, should be at least two inches and a half in diameter, consisting of an exterior row of large substantial well rounded petals, or guard-leaves, at first horizontally extended, and then turning a little upwards, so as to form a broad shallow cup, the interior part of which should contain a great number of long small petals, imbri- cating each other, and sooner reverting from the centre of the blossom; there are a great number of small slender stamens, intermixed with these petals, but they are short, and not easily discernible. The color should be clear and distinct when diversified in the same flower, or brilliant and striking if it consists only of one color, as blue, crimson, or scarlet, &c., in which case the bottom of the broad external petals is generally white; but the beauty and contrast is considerably increased when both the exterior and interior petals are regularly marked with alternate blue and white, or pink and white, &c. stripes, which in the broad petals should not extend quite to the margin.”

6278. Propagation. By seed for few varieties, and by dividing the root for continuing approved sorts.

6279. By seed. Select “single or semi-double flowers, that have strong, tall, and erect stems, large well formed cups, and petals of very brilliant colors. By sowing the seeds, which must be gathered in the autumn, the following method may be adopted: if the seed be sown in dry and light, it will otherwise be blown away by the first breeze of wind, or fall down and be lost; it may be sown at the same time, and be treated in all respects like that of ranunculuses; the seedlings will, like those, blow strong the second year. It will be found very difficult to sow another seed of a regular manner: it is united with, and developed in a downy substance, which being put together in quantity, adheres in such a manner as to render it necessary to make use of some sand or earth to separate it on sowing; nor will this be effected sufficiently without considerable labor in rubbing it for a long time amongst the earth, as it ought not to adhere together in lumps, which will not let the young plants space enough, even for their roots. There will be found but few double flowers amongst the seedlings, nor can it hardly ever be expected there should, if the seed be entirely saved from single ones; of course, the greater number of broad petals the flower of the seed-bearer possesses, so much greater is the probability of procuring large double flowers from the seed of it.”

6280. By dividing the root. When the division is properly made, every piece will blow the first year, and is therefore to be treated in the same way as such as are full-grown.

6281. Choice of full-grown roots. Select fresh plump roots of moderate size; large overgrown roots, which are hollow in the centre and often decayed, are to be avoided, as they never blow strong.

6282. Soil and situation, and preparation of the bed. The same as for the ranunculus.

6283. Planting and future culture. The distance between the roots may be the same as for the ranunculus. Attend to place that side of the roots next the soil in which the decayed rudiments of small thread-like fibres will be observed, and cover about two inches deep. “Anemones are harder than ranunculuses, and, consequently, may be always planted in the autumn with safety; the most advisable time is about the middle of October, by which means they will blow a week or two earlier than the tulips: if they are planted in a mixture of a certain light after the tulips, they will all bloom together; but a few days earlier or later in the planting will scarcely be perceptible at the time of flowering; it is, however, proper to observe, that such roots as are planted in October, will blow stronger, and, when taken up, will be found of a larger size than those that are planted towards the end of November, especially if the latter proves mild; but if the winter sets in early, and proves severe, late-planted roots will not have time to vegetate before frosty weather takes place; in which case there will be great danger of their perishing, unless they are covered with straw, just sufficiently to keep frost from the roots, as they are then in a state of inactivity, but replete with moisture, which renders them more susceptible of injury from frost, and, at the same time, in much greater danger of mouldiness than after vegetation has commenced. The covering must therefore be taken off and put on, as often, and in such proportion, as the exigency or circumstance of the case requires.” Water and protect from high winds and heavy rains, as directed for ranunculuses.

6284. Taking up the roots. “Anemones continue longer after bloom in a state of vegetation than ranunculuses, probably because of their greater degree of succulence; and even at the proper time to take them, when the heads become dry, and the foliage becomes all yellow, the parts of the root which are below the ground will not be entirely digested of greenness and moisture; this often will be the case when frequent showers of rain intervene, and are admitted between the times of blowing and the maturity of the roots: when it thus happens, much skill is required to ascer- tain the critical period to take up the roots; for if they are suffered to remain in the damp or wet ground a few days too long, they will contract a great deal of moisture, and be thereby materially weakened and injured; it is, indeed, better to take them up rather too early, than suffer them to re-vegetate in this manner; but the roots will not be so firm and solid as if done at the exact time. The safest and most effectual method to pre- serve the roots, if the times happen, that part of their foliage will not be entirely digested of greenness and moisture; this often will be the case when frequent showers of rain intervene, and are admitted between the times of blowing and the maturity of the roots: when it thus happens, much skill is required to ascer- tain the critical period to take up the roots; for if they are suffered to remain in the damp or wet ground a few days too long, they will contract a great deal of moisture, and be thereby materially weakened and injured; it is, indeed, better to take them up rather too early, than suffer them to re-vegetate in this manner; but the roots will not be so firm and solid as if done at the exact time. The safest and most effectual method to pre- serve the roots, if the times happen, that part of their foliage will not be entirely digested of greenness and moisture; this often will be the case when frequent showers of rain intervene, and are admitted between the times of blowing and the maturity of the roots: when it thus happens, much skill is required to ascer- tain the critical period to take up the roots; for if they are suffered to remain in the damp or wet ground a few days too long, they will contract a great deal of moisture, and be thereby materially weakened and injured; it is, indeed, better to take them up rather too early, than suffer them to re-vegetate in this manner; but the roots will not be so firm and solid as if done at the exact time. The safest and most effectual method to pre-
6285. The bulb of the crocus is round, solid, and compressed, with a netted skin, from the centre of which arise four or five grass-like leaves, and one or two flowers. Out of the centre of the tube of the flower arises a slender style, crowned by a broad flat stigma of a gold color. After the flower is past, the germ, which hitherto was seated on the bulb at the base of the tube, pushes out of the ground, and ripens its seeds; a singular economy in nature, and which occurs only in the colchicum, and a few other plants. All the known species of this genus may be considered as florists’ flowers. Many botanists, indeed, reckon only two species, the *C. vernus*, or spring-blowing crocus; and the *C. sativus*, the saffron, or autumn crocus.

From the *Crocus vernus* (Eng. Bot. 343, and our fig. 596), they consider that the *C. versicolor* (fig. 597), the *C. suiflorus* (fig. 598, a), the *C. susianus* (b), the *C. sulphureus* (c), and the *C. maritimus* (d and e), with their numerous sub-varieties, have been produced by culture or locality.

From the *Crocus sativus*, or saffron-crocus (Eng. Bot. 343, and our fig. 599, a), they think it likely that the *C. arrotinii* (fig. 599, b) and the *C. multiflorus* (fig. 599, c) have been also originated by cultivation or accident.

6286. All the sorts of crocus have been, time out of mind, and still are, great ornaments to the garden; the spring sorts coming into flower in February and March, and the autumn sorts in September and October. The color of the spring crocus in its wild state, in Switzerland, is white with a purple base; it is considered as naturalised in England, but, when found wild, is almost always of a yellow color. The autumn crocus, or saffron, is also found wild in some places, and considered as naturalised; but it appears to be an African plant, which its Arabic name, sahafaran, seems to justify, and introduced originally in Edward the Third’s time. Its color is generally purple or blue, as is that of most of the autumn varieties in cultivation at present.

6287. Varieties. None of these are double. Of the spring crocus, Parkinson has enumerated twenty-seven varieties; the fundamental colors of which are blue, purple, yellow, and white. Miller recites twelve as leading sorts. Mason’s catalogue for 1820 mentions “twenty named sorts,” besides the light, dark, and striped purple, cloth of gold, the Scotch crocus beautifully striped, the white, the large and small yellow, and several striped sorts. The Dutch are continually producing new varieties, as are some florists in this country, of which Haworth (Hort. Trans. i. 122.) may be cited as an instance. Of the autumn crocus, Parkinson has enumerated four, and Ray six varieties. Miller has only four: the sweet-smelling, of a deep blue; the mountain, of a paler blue; the many-flowering, bluish; and the small-flowering. Most of these varieties are now lost.

6288. Criterion of a good crocus. Clear or brilliant colors, and each color distinctly marked and finely pencilled in the striped and variegated sorts.

6289. Propagation. By seed, for new varieties; and by offset-bulbs, for common
purposes. The latter generally flower the first spring after planting, and are treated in all respects as full-grown roots.

6200. By seed. The following directions are by Haworth. "The seeds of crocuses are best sown, immediately after being gathered, in light dry earth, in large pots, or pans, or small shallow boxes, with a sufficiency of holes and potsherds at the bottom, for the purpose of draining off with certainty all superfluous moisture thinly; for almost every seed will germinate, and cover not more than half an inch with sand, earth, or peat. They are sown at the end of winter or in the beginning of spring, all being set, in a moderately shy yet unsheltered one: permitting them to receive all the influence of the weather, except such heavy showers as would wash bare the seeds. As soon, however, as the autumnal rains have moderated, or if the dewy aspect of nature should remove them from all excessive rains, frosts, and snows, by the occasional shelter of a garden-frame: allowing them to be covered with the full air at other times, but more especially after the seminal leaf (for they have but one, being monocotyledonous plants), eager to commence the career of life, urges its fine secatitious point above the surface of the earth. This occurs sometimes about the end of the year, but often in earliest spring. As this it is quite essential that they should have complete exposure to the air, even in frosty weather; screening them, however, occasionally, like early rudishes, with loose straw, from other injurious effects of frost; so as to prevent their being raised out of their infantile beds by its baneful effects. In this manner may they continue to flower and fruit, and until the earth is to be sown by all means to dry the earth in their boxes, as to require daily waterings. It will be then found advantageous to remove them to a cooler, but not sheltered situation, and here they may remain until their leaves die down; giving them, as just hinted, at all times, and in every situation, while their leaves are growing, such discretionary waterings, when the sun is not shining, as they may reasonably appear to require: but never until the earth they grow in becomes dry: not any whatever, after their leaves begin to look yellow. After this period, it is necessary to defend them from all humidity, except dews and gentle rains, until the end of August, or beginning of September.

6201. From seeds, worms, slugs, and snails. "It is almost needless to observe, they should constantly be kept as clear as possible. And if the surface of the earth in their boxes is occasionally stirred with the point of a stick, oil, or piece of stick, it will prevent accidental effects, and invigorate the bulbs: operating no doubt, as a sort of hoeing, and, like that important practice, (as the writer of this paper conceives,) proving salubrious to vegetables of every denomination, not only by lightening the soil, but by admitting new accessus of atmospheric air towards their roots; and thereby facilitating, and stimulating their absorptive inspiration of all oxygen; without a due supply of which all vegetables, as well as animals, eventually become feeble and sick. If, notwithstanding the precaution of thinly sowing the seeds, the plants in any of your seminal boxes should have grown so thickly together as to have incommoded each other, it will be desirable to have such taken up, and replanted into a number of boxes, about the middle of March, and about a month, if the bulbs are not too crowded, they will require no shifting this their first autumn; but merely about a quarter of an inch from mould sifted over them, previously stirring and cleaning the surface of the old manure off the young; and observing not to bury the young shoots not yet so large as lentils, deeper than the quarters of an inch, or an inch at the most. The second season requires exactly the same management as the first. But as soon as their second year's foliage has pass'd away, the roots should all be taken up, and replanted again the same or following day, into fresh earth, of the same kind as before, also carefully treated as much as possible, and treated as above. Nor does the third season demand any alteration in their management; sitting over them in autumn half an inch of fresh earth. The spring following, if they have been duly attended to, most of them will show flowers (a few, perhaps, having dropped their season before that,) in the month of the fourth crop of leaves; fully rewarding with the cheering colors of their new faces all the preceding industry and care." (Haworth, Trans. 25.)

6202. Choice of bulbs. Observe that the base is not mouldy, nor the bud or summit of the bulb decayed.

6203. Soil, situation, and culture. They will grow in any good soil; but prefer a loamy sand. October is the best season for planting; the more select varieties are grown in beds like the hyacinth, and the colors mingled in the same manner; the distance from bulb to bulb about three inches. The more ordinary sorts are grown as border-flowers, and form an important part of the early flowers of the front row. (p. 197.) As their roots are very shady, and require no care till the leaves begin to fade, when they should be taken up, and kept in a rest of two or three months. Some do not take them up oftener than once in three years, which answers very well for the border sorts. Even these, however, should not be left to the young bulb; when their growth is formed on them, they come nearer to the surface every year, till at last, when neglected, they are thrown out and lost.

6204. The bulb of the narcissus is pear-shaped and tunicated, the leaves succulent and linear, and the flower-stems, which are from six to eighteen inches in height, bear either solitary or fasciculated flowers; the color of the flower is either white or yellow, and generally odoriferous. Most of the species are natives of the south of Europe, but one, the N. Pseudo-Narcissus, is a native of England, and common in woods in clayey soils. They come into flower in February, March, and April.

6205. Species and varieties. The popular division of this genus is into daffodilis, white narcissus, jonquils, and polyanthus narcissus.

The daffodilis are N. Pseudo Narcissus (Eng. Bulb. Mag. 6.) The varieties are the common double, the double with white petals and a yellow cup, the single with yellow petals and a gold color around the edge of the cup, Tradescant's daffodil, and above a dozen other nameless varieties; the peonies, and the yellow daffodil (N. Bulb. Mag. 6.) (Eng. Bot. 27.) and a variety (N. Bulb. Mag. 6.) (Eng. Bot. 27.) kept for the scope; the two-colored daffodil, or the Muscari daffodil (N. Bulb. Mag. 6.) (Eng. Bot. 27.) native of Spain, and a variety of the great yellow Spanish, the largest flower of the genus; the least daffodil (N. Bulb. Mag. 6.) (Eng. Bot. 27.) (Botal. Mag. 6.) the rush-leaved gaudy daffodil (N. Bulb. Mag. 6.) (Eng. Bot. 27.) with some other species and varieties. The white narcissus are the poets' n. Narcissus (N. poetica); the early-flowered (N. p. angustifolium); and the later-flowered (N. p. bulbifera) the musk-narcissus (N. muscatus) (Eng. Bot. 27.) the eastern narcissus (N. bulbifera) (N. Bulb. Mag. 6.) (Eng. Bot. 27.) the wild or counterfeit daffodil (N. Bulb. Mag. 6.) (Eng. Bot. 27.) the yellow and large-flowered varieties; the yellow jonquil (N. bulbifera) (Batal. Mag. 6.) the yellow jonquil (N. bulbifera) (Batal. Mag. 6.) and the yellow jonquil (N. bulbifera) (Batal. Mag. 6.) with other varieties.

The jonquils are the common (N. jonquillus,) the jonquils (N. jonquil) with some minor varieties. The yellow jonquil (N. bulbifera) (Batal. Mag. 6.) the great jonquil (N. bulbifera) (Batal. Mag. 6.) and some minor varieties. The polyanthus narcissus are the common (N. Jonquil) with some minor varieties. The sulphur-colored, single and double; the white with yellow, single and double; and above a hundred other sorts, with anthing varied in the upper petal, single and double. All the varieties who have highly improved this division of the genus. Some of these sorts are considered species by botanists.

6246. Criterion of a good narcissus. Strong erect stems; regularity of form and disposition in the petals and nectars; distinctness and clearness of color; and in the many-flowered sorts, the peduncle all of the same length, and coming into flower at once.

6297. Propagation. By seed for new varieties, but generally by offsets, which, as they
seldom flower the first year after separation, should not be planted with the full-grown roots, but in a bed of light loamy soil by themselves in the reserve-garden. They should not be planted later than the beginning of September.

628. By seed. Miller directs to sow in flat pans, filled with fresh, light, sandy earth, about the beginning of August, soon after the seed is ripe; to place the pans where they will receive only the morning sun till October. Then expose them to the full sun, and protect them from heavy rains and frosts until April, when they will have come up, and must be removed to their first situation. In June, the leaves will have decayed away, and the bulbs should be shifted to the second situation. The end of the second after sowing, the roots are to be taken up and planted at about three inches' distance every way, in beds raised and rounded to throw off the water. These beds are to be protected in winter by old tan-ashes or manure. After remaining two years in this situation, they are to be taken up and planted in others, dug deep, and with a little rotten cow-dung buried in the bottom of the fibres to strike into. Here the roots are to be planted at six inches' distance, having earth sifted over them when the leaves decay, and tan or ashes in winter. The second season of their growth in this bed, that is, the fifth from sowing, most of the bulbs will come into flower. Such as are esteemed good flowers may be taken up and treated as full-grown bulbs; but those which have not flourished, or of which the flowers are of doubtful excellence, may remain another year. Miller says, none should be rejected till they have flowered two or three times: as it often happens, that their first blowing is not so near so beautiful as their second and third.

629. Choice of full-grown bulbs. Select such as are rounded towards the base rather than compressed, with full sound tops, and bottoms free from mouldiness or decayed fibres.

630. Soil, situation, and planting. As eastern aspect is to be preferred; and, according to Miller, the best soil is fresh, light, hazel loam, mixed with a little very rotten cow-dung. The bed in which they are to be planted must be excavated three feet deep, and filled with this compost, and then the roots planted on it about eight inches' distance every way, and covered from six to eight inches, in the manner directed for tulips. The best time for planting is August, or the beginning of September.

631. Culture. Stirring the soil, weeding, and watering are all that is in general required: but such as wish to produce a very perfect show of flowers, shelter with an awning in the manner recommended for hyacinths. In winter, the beds require the protection of tan or litter, which should be put on in October or November, and removed, and the soil stirred in February or March. Where the narcissi are cultivated for commercial purposes, the strength of the bulb is greatly increased by cutting off the flower-stem when the flowers begin to expand. The flower is still valuable, being expanded till in a marketable state, and with some freedom. Some years it is cut off and dried, and seeds sown in the grounds of Daniel Carter, at Fulham, who has long cultivated large quantities of polyanthus narcissiuses for sale, and was surprised to find all the crop nearly gathered, though very early in the season. His son, however, explained the mystery, by taking me into a large barn, which was filled with the gathered flowers, blown off the stalks and the roots cut off. By doing this, the bulbs continued to produce as abundant crops every year, as new ones imported from Holland. The practice was suggested to him by remarking, that in a bed left for seed one year, very few roots sent up a complete bunch of flowers the following season, and many roots none at all. He therefore now cuts off the stalk close to the ground, as soon as two or three of the flowers are expanded, but is very careful not to injure the leaves."

632. Taking up the bulbs. The bulbs should not be taken up oftener than every third year, if they are expected to flower strong and make a great increase. If they remain longer than three years, the offsets will become so numerous as to weaken the bulbs, which will at first flower weakly, and in time cease almost entirely to show flowers. The Dutch take up these roots every year, because their object is to furnish a round plumpt root, and the way to accomplish this is to take off the offsets annually, to prevent their pressing against and flattening the parent bulb. The bulbs being dried in the shade, may be laid in an airy situation in the seed-loft till wanted for planting.

633. Forcing. These bulbs force well, and either in deep pots of sandy loam, or in water-glasses; their previous treatment is the same as we have prescribed for the hyacinth; and they are highly odoriferous and ornamental in apartments.

**SUBJECT 7. Iris. — Iris, L. Trian. Monog. L. and Iriceae, B. P. L'Iris, Fr.; Schwertllilie, Ger.; and Iride, Ital. (figs. 600, 601.)***

6304. There are several species of iris which are considered florists' flowers.

The Persian iris (I. Pernica) (Bot. Mag., and our fig. 600) is a very low bulbous rooted plant, with delicate blue and violet-colored flowers, greatly esteemed for their beauty and sweet smell, which is so powerful that one plant will scent a whole room. It is a native of Persia, and was cultivated by Parkinson in 1629. The bulbs are generally imported from Holland, and blow in water-glasses, or pots of sand with very little earth intermixed, in February and March.

The snake's-head iris (I. Tuberosa) (Bot. Mag. 531, and fig. 601 b) has long narrow four-cornered leaves, and a dark purple flower, which appears in April. It is a native of the Levant, and was cultivated in 1597. The tubers are generally imported from Holland.

The Chalcedonian iris (I. Eustasia) (Bot. Mag. 94, and fig. 600 a) has finely straited leaves, a scape a span high, and the largest and most magnificent coryds of all the species. Its petals are of a delicate texture, almost as broad as a hand, purple or black,
striped with white. It flowers in the beginning of June; it is a native of the Lebanon, and was cultivated by Jererand in 1595.

The bulbous or Spanish iris (I. piphitina; Bot. Mag. 569, and fig. 601, a) has channelled leaves, convoluted during their whole length, and awl-shaped at the tip; the flowers of the wild plant are blue, with emarginate petals, and appear in June; but cultivated produced a number of varieties with yellow, white, violet, and magenta shades of flowers. It is a native of the south of Europe, and was cultivated by Gerard in 1595.

The following is a list of the bulbous and tuberosous, the English Iris of the Dutch, (I. xiphoides) (Bot. Mag. 602, and fig. 601, b), it much larger than the other in all its parts, the flower-stalk is twice the height, and the flowers are more than double the size. It is equally prolific in varieties as I. xiphoides, of which it is by some botanists considered only a variety. The takers of both sorts are annually imported from Holland.

6305. Culture of the first three species. These seldom ripen their seeds in this country, nor are they often propagated from offsets, annual supplies of bulbs being obtained from Holland, and generally forced like the hyacinth. Justice says (Brit. Gard. Direct. 222.) the Dutch florists told him, that they never could obtain any varieties from sowing the seeds of the Persian iris; nor could this author himself, who cultivated the plant, and raised seedlings at Crichton, near Edinburgh, with great care and considerable success. The three sorts are best cultivated under the protection of a frame, where their flowers will be less liable to injury than in the open air, and where their leaves will be stronger and more able to nourish the bulbs and offsets. The Chalecedonian iris, Curtis observes, thrive best in a loamy soil and sunny exposure, with a pure air, but guarded from moisture, and from frosts during winter. The Persian iris thrives best in a light sandy loam and eastern exposure, sheltered from rains and frosts, like the other. The snake's-head iris is the hardest of the three, requires the same soil and exposure as the Persian, but less care during winter. None of these sorts need be taken up oftener than once in three years, when the leaves decay; they should be replanted in a month or six weeks afterwards, at six inches' distance every way, and covered from two to four inches according to the size of the bulbous tuber.

The soil in which the bulbous and tuberous sorts of iris is planted be loose and deep, and the plants not taken up every three, or at most four years, they will run down and be lost. 6306. Culture of the bulbous irises. Miller and Justice recommend a light sandy loam, not rich, and an eastern exposure for the plants, which are abundantly produced and sold, and as they also produce seeds freely, many valuable varieties are obtained in that manner. Justice says, he raised a great number with very little trouble (Brit. Gard. Direct. 430.) and Masters says, "I know no flower that better repays the time and attention of the horticulturist." The following are this author's directions for its propagation by seed.

It is propagated chiefly from seedling produced on all seedling plants, although, like many other plants, but sparingly, and very frequently not at all, on such as have been long increased by offsets, or parting the roots; they may be sown in slight drifts, about six inches asunder, as soon as ripe; and in the March following, they will make appearance very similar to ripple. If they are grown in the seed-bed for three years, for they are much the most tender than most kinds of seedling bulbs, and, therefore, will not even require protection from the frosts. In August or September of the third year, it will be necessary to transplant them into beds, at a distance of four to six inches square, that the bulbs from the surface of the ground, most of the strongest will show blossom, and nearly all in the year following, or the sixth from the seed. If, during the time the roots are at rest, the top surface of the earth is carelessly removed, and fresh light loam is substituted, the year will be lost, this treatment will greatly promote the growth of the bulbs, and with these, as well as many other seedling plants, it is not a stated time that must pass before they blossom, but only such a portion as will allow the bulb to attain a size sufficient to contain vigour to produce and perfect a flower-stem, the rudiment of which is formed in the preceding summer. When the blossom is over, and the vagaries perpetuated by the increase of their offsets. The most proper time for removing the bulbs is in August and September, those kept out of ground until Christmas rarely blossom in the succeeding summer." (Hort. Trans. iv. 413.)

6307. Flowering bulbs. Every third year, in August, is the most proper time for taking them up; and they should, if possible, be replanted by August or September. Masters says, those kept out of ground till Christmas rarely blossom in the succeeding summer. They may be planted either in beds, at eight inches or a foot distant every way, or in mingled borders, care being taken in each case to prevent the roots running down by removal every third year, or by a substratum of tiles or compact rubbish within eighteen inches of the surface. These species are very hardy, and flowering so late as June, require no protection either in summer or winter. They are seldom or never forced.

Sec. 8. Fritillaria.—Fritillaria L. Hexan. Monog. L. and L. (fig. 602.)

6308. Of the fritillaries there are three species which are considered as florists' flowers; of these species there are numerous varieties.

The crown-imperial (F. imperialis; (Bot. Mag. 191.) Le Couronne Imperiale, (Gyn.) Kroneblume, (Ger.); and Crown Imperiale, (Ital.); fig. 601, a) is a scaly bulb with a single stem, from two to four feet in height, furnished with alternate green leaves, and crowned with a showy panicle of small yellow flowers, to two more or less, or more in successive years, which appear in March and April. It is at its best in the month of the flower-garden, producing a fine appearance when in flower, and for some years at a season when such flowers are most wanted. The "singular varieties," Preston Mason observes, "cannot but engage the attention of the curious observer, and is a white glabrous cavity as the base of each petal, and has a drop of".
6309. Propagation. The common method is by offsets; but they may be raised from seed, which ripens readily, and is to be treated in all respects like that of the tulip, the seedlings of the crown-imperial flowering in the fifth or sixth year, and those of the other species in the third or fourth year.

6310. Culture of flowering bulbs. They are planted in a light soil on which no manure was used the two years previous. It should be dug deep, and the bulbs may be planted six inches deep, and from eighteen inches to two feet distant every way; but they have the best effect in a mingled flower-border. They need not be taken up above once in three years, when the stems are withered in May or June, and they should not be kept longer out of the ground than two months.

6311. Of the lily there are sixteen species introduced into Britain, and of the whole of them may be reeoned very choice flowers. We shall notice particularly, only those species, of which numerous varieties have been produced. These are:

The white lily (L. Candidum) (Bot. Mag. 274.) has a large scaly bulb, a leafy stem, from three to four feet high, and terminating in pure white flowers in peduncles. It is a native of the Levant, and was introduced in Gerrat's time. Of this species there are above eight varieties.

The orange lily (L. bulbifemor) (Bot. Mag. 36.) has a scaly bulb, a leafy stem, two feet and a half high, terminating in orange-colored flowers. Sometimes the stem produces small green bulbs in the axille of the leaves. Of this species there are also five varieties of varying colors and sizes.

The marigold, or Turk's cap, (L. Major-, (Bot. Mag. 585.) has a large scaly bulb, a stalk furnished with narrow leaves, three feet high, and terminating peduncles of fine carmine flowers in July. Of this species there are half a dozen varieties, besides the scarlet marigold, (L. Chalcedonica,) of which there are also different sorts. Besides the above varieties, there are the L. Candidum, rothdum, or Oriental lily; L. martagon, or Tigrinum, and Tigerlily; the L. japonicum, or Japan lily, with stems of 3 ft., and the Double, a pure white with a streak of blue; all equally meriting cultivation as select flowers.

6312. Propagation. This is almost always by offset-bulbs; but new varieties may be raised from seed, which ripens in most sorts in August; being treated as directed for raising new varieties of the narcissus, the young bulbs will flowering the fourth and fifth years.

6313. Culture of flowering bulbs. The more common sorts, species, and varieties, will thrive in any soil and situation, even on the shade of trees. The Canadian, Pompomum, and Philadelphia varieties are grown in borders, and the protection of ashes or leaves in leafy shade in winter. They are generally planted in borders, and need not be taken up oftener than every three or four years in September, and replanted six inches deep in the October following. None of the species can be safely transplanted after they have pushed leaves, without weakening them so as to prevent their flowering for several years. The following general rules will assist in the cultivation of bulbous-flowering plants. Griffin, of South Lambeth, whose superior skill in the cultivation of bulbous plants is well known (Hort. Trans. iv. 544.), has been in the practice of keeping the lilium japonicum in pots, protected by a green-house or garden-frame; but he thinks they thrive best in the open ground. He recommends in twenty-four, or thirty, or forty pots, not larger than an inch from the surface of the mould, which is composed of about two thirds peat and one third loam, the bottom of the pot being covered to the depth of two inches, with broken pieces of tile and the rough sittings of peat. The plants are kept entirely from frost, and are watered very little when in a dormant state, and once only in June. They are then very impatient of the heat of the sun, for at the green houses kept at a distance from the sun to prevent the mould drying quickly. (Hort. Trans. iv. 544.) Brooks grows in a brick-pit, which he can cover with mats or glass at pleasure; but he says, it "appears to be sufficiently hard to endure our winters, as I have had a bed of them two years in the open ground without protection." (Hort. Trans. iv. 552.)

6314. The Amaryllideæ is a splendid family, lately subdivided into those of Nerine, Colubrina, and Brunsvigia (see Bot. Mag.), of which almost every species may be considered a select flower. The A. amabilis, Josephina, and Vittato, are reckoned the most splendid bulbous-rooted plants; and the A. formosissima, or Jacobea lily; Sarnoensis, or Guernsey lily; Belladonna, &c. are less magnificent, but of very great beauty. Most of the species are green-house or stove plants, and natives of the Cape of Good Hope, China, or South America. Various hybrids of this family have been produced by Herbert, Sweet, Gower, and others. (Hort. Trans. iv. 488. &c.)

6315. Propagation and culture. New sorts, as in similar cases, are procured by seed; but the most usual mode, as few of these plants have ripened their seeds in this country, is by offsets from the flowering bulbs, removed yearly, or every time the bulbs are taken out of the ground. The great art in cultivating these, and all other bulbs, is to procure vigorous leaves, as on these depend the quality of nutritious matter prepared and collected by the bulb, and consequently its ability to flower the following season. The cultivation of offsets is of several of these plants, as the Guernsey lily, flowering in the autumn, and producing their leaves afterwards under the disadvantages of a winter's sun, is the reason why they have been hitherto cultivated with so little success in this country, and why we are obliged to import the bulbs annually from France. The advantage of this on this subject are particularly valuable; they more immediately refer to the Guernsey lily, but they are equally applicable to all exotic bulbs. " Bulbus roots increase in size, and proceed in acquiring powers to produce blossoms, only during the periods in which they have leaves, and in which the tubers are exposed to light; and these organs always operate most efficiently when they are young, and have just attained their full growth. The bulb of the Guernsey lily, as it is usually cultivated in this country, rarely produces leaves till September, or the beginning of October, at which period the quantity of light received is equal to that of the warm and bright climate of Japan; and before the return of spring, its leaves are necessarily grown old, and nearly of office, even when they have been safely protected from frost through the winter. It is, therefore, not extraordinary, that a bulb of this species, which has once experienced the power of itself in all the powers of itself, should but very slowly develop the powers of itself, again. Considering, therefore, the deficiency of light and heat, owing to the late period of its vegetation, as the chief cause why this plant so often fails to produce flowers, I inferred that nothing more was required to make it blossom, as freely, at the end of the short period it is in Guernsey, than suitable supplies of artificial heat, applied in the most efficient manner, as would prove sufficient to make the bulbs vegetate a few weeks earlier than usual in the autumn. Early in the summer of 1816, a bulb, which had blossomed in the preceding autumn, was subjected to such a degree of artificial heat, as occasioned it to vegetate six weeks, or more, earlier than it would otherwise have done; I had not, of course, produce any flowers; but in the following season it blossomed early and strongly, and...
afforded two offsets. These were put, in the spring of 1818, into pots, containing about one eighth of a square foot of light and rich mould, and were fed with manured water, and their period of vegetation was again accelerated by artificial heat. Their leaves, consequently, grew yellow from maturity, early in the present season, when the pots were placed in rather a shady situation, and near a northerly wall, to afford me an opportunity of observing to what extent, in such a situation, the early production of the flowers in the preceding seasons had changed the habit of the plant. I entertained no doubt but that both the bulbs would afford blossoms, but I was much gratified by the appearance of the blossoms in the first week in June. Among the offsets of the preceding year and experiment, two bulbs of this plant which have produced flowers, be placed in a moderate hot-bed, in the end of May, to occasion the early production of their leaves, blossoms would be constantly afforded in the following season. These plants to have gradually to the open air, as soon as they are nearly fully grown, and to protect them from frost till the approach of spring.

6315. The Rev. W. Williamson has adopted the same rationale as Knight; and, with the aid of a glass frame, without artificial heat, brought bulbs which had flowered into a state to flower again after two winter's. Had he adopted artificial heat, he thinks one winter might probably have been sufficient. (Hort. Trans. iii. 450.)

6317. The Hon. and Rev. W. Herbert has found a similar treatment attended with corresponding success. He says, "the lily requires here (Spofforth, Yorkshire), to give it sufficient air while the leaves are growing, that they may be strong and dark-colored; to protect the leaves from frost, keeping the pots near the light, if under glass; to give a moderate and regular supply of water, and to leave the bulbs nearly dry, from the time the leaves decay, that is, about midsummer, at latest, to the end of August, when the flower-buds should appear. If the bulbs are not left dry early in the summer, the autumnal shoot will be delayed till the season becomes too cold for the proper growth of the flowers or leaves, and the natural course and vigor of the plant will be interrupted, after which it will require at least a year to repair the injury it will have received. Whenever the propagating of the bulb is tardy, it is advisable to assist by placing it, for a short time, in a warmer situation. If the stigma does not expand so as to become, after a few days, trifid, it is a sign that the temperature is rather too low to suit the plant, and the leaves will probably not push freely without more heat. I have obtained seed from the Guernsey lily by procuring the blossoms in an airy situation." The soil Herbert recommends is a good yellow loam, without any manure; but he thinks "they will thrive in any wholesome compost, which does not cancel their bulbs. They should be planted partly above ground, for the wet earth round their necks will prevent their flowering or thriving, and will even sometimes destroy them." (Hort. Trans. iv. 177.) The same treatment, with a little more caution, suits the whole of the bulbs included under amaryllis, as well as a number of other allied genera, as hennanthes, pantcratium, agapanthus, &c. Some species of these genera, as Amaryllis longifolia, W. and Crinum Asiaticum, are of dry ditches in the Baltic and of flats in the soil of Bengal, where they root deeply in the mud. These species of Herbert found to succeed perfectly when plunged during summer in a pond. "Most of the crinums," he says, "are swamp plants, or grow in river-mud, and should be cultivated in our stoves, with a pan of water under them, the bulbs being raised above the earth, and stripped of all dead intergrowths. Agapanthus, including lachenalia, flowers best when so treated; the Amaryllis longifolia (which, he says, should be named Crinum capens) will," he has no doubt, "flower as a hardy aquatic, if planted in any pond or river of two feet water, not liable to freeze at the bottom." (Hort. Trans. iii. 188.)

6318. Some account of the cultivation of the Guernsey lily in the Island of Guernsey is given by Dr. Macculloch (Caled. Mem. ii. 62): there they grow it in the open air, and protect it with sand during winter.

Subsect. 11. Ixia and Gladioli, W. / Trian. Monog. L. and Irideo, B. P.

6319. The ixia and gladioli include a number of recently formed genera (see Bot. Mag. and Bot. Reg.) of Cape bulbs, which may be flowered in the open air, under frames without bottom heat, or on shelves near the glass in green-houses. The Hon. W. Herbert, who has paid great attention to the culture of bulbs, is "persuaded that the African gladioli will become great favorites with florists, when their beauty in the open border, the facility of their culture, and the endless variety which may be produced from seed by blending the several species, are sufficiently known, nor will they be found to yield in beauty to the tulip and narcissus." (Hort. Trans. iv. 154.)

6320. Propagation and culture. They may either be propagated by seed or offset-bulbs; by the former mode, Herbert has produced numerous beautiful varieties. The proper soil for these and similar bulbs is peat, on a bed of this is sown the seeds, which are sown in spring, and well watered before and after they come up. "At the beginning of October, or as soon as the leaves wither, the bulbs should be taken up and dried; they may be replanted again at any time, placing them about eight inches under ground, to prevent the frost reaching them. Next year they will generally flower." The best way of treating gladioli which are to be flowered in pots is, when the bulbs are potted, to plunge the pots about eight inches under ground in a bed of peat, and raise them nearer the surface in spring, as soon as the very severe frosts are over; or not to plunge them so deep, and protect them with moss, leaves, rotten tan, &c.

6321. Various other bulbens irideas, and also oxalis, lachenalia, cyclamen, &c. may be successfully treated in a similar manner. (Herbert, in Hort. Trans., Mัดdock, in Flor. Dir.)

6322. The tuberos is a bulbous-rooted plant, with linear leaves of a whitish green, and stems four or five feet high, terminating in a sparse spike of white flowers, of very powerful fragrance. It is a native of India, whence it was first brought to Europe about 1524, and to England in 1629. It is generally cultivated in frames or the green-house, but in warm situations will flower in the open air. The tubers of this plant are annually imported from the warm provinces of North America and Italy, but, like those of the Guernsey lily, might, by proper treatment, as Salisbury has proved, be produced in this country equally fit for flowering. There is a double variety, which is in moss-teem, but both are equally fragrant.

6323. General treatment. The bulbs are planted in pots of sandy loam in March or April, and brought forward in a hot-bed or hot-house till the flower-buds begin to ap-
The plants are then removed to the greenhouse or the open air, or to halls or churches, as in Italy, where the cooler temperature procures a prolonged bloom.

6324. *Culture to produce flowering roots.* The following is the process followed by Salisbury, by which he produced, for many years, in the open air at Chapel Allerton, flowering bulbs equal to those imported.

The situation he preferred was a dry warm border; in this he made an excavation two or three feet deep, and of any convenient length and width; about the middle of April, he filled this pit with fresh stable-dung, and covered it with light sandy earth; then, on the bed so formed, the small lateral roots, or those from foreign bulbs, or from those which had flowered in this country the preceding year, and been preserved through the winter in sand, were planted at five inches distance every way, the upper part of the tuber being just covered with earth. The bed was protected from nightly frosts and heavy rains, little or no water was given, but when the leaves were an inch long, a little fresh compost was added to the surface. In June and July, when the leaves were in full vigor, it was watered copiously after warm days; but in autumn and the beginning of winter, it was carefully protected from heavy rains. In the beginning of December, the decayed leaves being removed, the bed was thatched over a foot thick with dry straw, sloping it well to throw off the wet; or covered with a frame and litter. In February the roots were taken up preserving their fibres, and packed in dry sand in a cellar where the cold could not penetrate, till April, when their fibres being shortened in proportion to their decay, and all the offsets excepting one or two on each bulb being removed, they were replanted as before. A few strong roots flowered in this second year. In the succeeding winter the bed was thatched as before, and in February the roots were taken up preserving them half where they were, and those which tubercle-roots are grown. By this process bulbs were produced equal, if not superior, to those imported; and therefore the author thinks their culture might become an object to the commercial gardener, especially in the southern counties near the sea, and in the vicinity of London. The great object, he says, is to obtain "a sufficient degree of heat in summer to bring their leaves out to their full magnitude, that of the roots following of course. The theory," he adds, "which I would recommend any intelligent gardener to adopt in its general management is, to keep the roots growing as vigorously as possible from May to October, but in a state of complete rest and drought for the remainder of the year." (Hort. Trans. i. 53.)

6325. Most of the species of *Paeony* introduced in this country may be considered as select flowers; but that which has been longest cultivated is the *P. officinalis* (Bot. Mag. 1784.) The roots are composed of roundish tubers, the stalks of the leaves rise between two and three feet high, and terminate in large red or purple flowers, which appear in May. The leaves are composed of many unequal lobes, variously cut into many segments. It is a native of Switzerland, Dauphine, and other parts of Europe, and also of China and Japan; and was cultivated here in 1562. The roots were formerly much used in medicine.

6326. **Varieties.** Originally the common *Paeony* was said to be of two sorts, male and female, the flowers of the former being smaller and lighter colored than those of the latter. These distinctions, which had no sexual allusion in this case, the *Paeony* being hermaphrodite, are now laid aside, and the varieties of *P. officinalis* have been reduced by Sabine (Hort. Trans. ii. 273.) to the following:—

The double red; the most common, and formerly highly prized; being, when introduced at Antwerp, near 250 years ago, sold for twelve crowns.

The double flesh-colored; the most common, and formerly highly prized; being, when introduced at Antwerp, near 250 years ago, sold for twelve crowns.

The double white; the most common, and formerly highly prized; being, when introduced at Antwerp, near 250 years ago, sold for twelve crowns.

The double sweet-scented Chinese (Hort. Trans. vol. ii. pt. 15.) Whitely's double white Chinese.

6327. Propagation and culture. By seed from the single and semi-double sorts for new species, and by dividing the roots for ordinary purposes. Miller directs to sow the seeds which ripen in September, immediately afterwards in light fresh earth, and they will rise the following year. From the seed-bed two years before they are transplanted, sifting a little rich earth over them when the leaves decay at the end of the growing season. Having made two years' growth in the seed-bed, they are to be transplanted in September into other well prepared beds of light fresh earth, and placed six inches asunder every way, and three inches deep. Here they are to remain till they flower, which is generally the fourth or fifth summer after sowing.

6328. **Full-grown roots are readily propagated by parting,** taking care to preserve a bud on the crown of each offset. The plants are very hardy; they will grow in almost any soil and situation, and even under the shade of trees, where, in summer, they continue second in beauty. They are chiefly planted in flower-borders, and form a splendid ornament both to the parterre and shrubbery.

6329. The roots of the *Dahlia* are tuberous and fasciculated; the stems rise from five to eight feet, covered with large compound leaves, resembling those of the common *dwarf* elder, and with side branches bearing numerous flowers of a great variety of colors, which appear in August, and continue till destroyed by frost. The plant grows wild in Mexico, in sandy meadows, and was sent to Madrid in 1789, and thence to England in the same year; but the plants being lost, seeds were reintroduced by Lady Holland in 1804, and from these and some plants imported from France during the peace of 1814, the present extensive stock of dahlias has originated. Till this last period they were much more cultivated in France and Germany than in England, and more especially by the Count Lelièvre, at Paris, and Otto, at Berlin. At present the *Dahlia* is the most fashionable flower in this country, and the extent of its culture in some of the nurseries, especially that of Lee, is truly astonishing. Nor is this to be wondered at, as Sabine observes, for, indenendently of the great beauty and diversity of the
flowers, they are in perfection at a season when, till they came into notice, our gardens had but little ornament. The roots are edible, but not agreeable.

6330. The varieties are exceedingly numerous.

The leading varieties of the fertile-rayed species are those of large, dark-purple, pale, white, sulphur, yellow, tawny, greenish, bronze, pomegranate-colored, dark-purple, very dark, and lilac flowered single, semi-double, and double, with innumerable sub-varieties, of all which species, 

Of the barren-rayed species, D. bracteata, there are the scarlet, orange, saffron, and yellow flowered, single, semi-double, and double, with several sub-varieties, though this species has not ripened nearly so much as the other.

At the Queenshine nursery, above 200 sorts may be procured.

6331. Criterion of a good dahlia. The plant is short, stiff, and bushy, prolific in flowers having short peduncles; the flower well expanded and standing boldly to view, and the colors clear and distinct.

6332. Propagation. By dividing the roots, and by cuttings for ordinary purposes; and by seed for new varieties and also for increasing the stock of this plant, as the seedlings flower the first year.

In dividing the root care must be had to preserve a bud to each section, otherwise, though the tubers will throw out new shoots, they will not produce leaves.

6333. By cuttings. Take those from the root-shoots in spring, or the tops of the young shoots, as early in summer as may be; cut the lower end smoothly off in the middle of a joint, and leave the leaves on the top, excepting such as would be buried in planting the cutting. Plant in sandy earth on heat, and cover with a hand-glass, and they will strike and produce both flowers and tubers before the autumn.

6334. By grafting. This mode of propagating herbaceous vegetables has been known for some time on the continent, and practised, as we have seen (1832.), to a considerable extent by the Baron Teucheni.

In this country it seems to have been first adopted by Blake, in 1830, as a more speedy mode of propagating double-flowering plants than striking by cuttings. The following are the details of his practice:—The cutting intended for the graft should be strong, and short-jointed, having on it two or more joints or buds; it must be also procured as soon as possible, for if kept more than 24 hours, it will wither. The cutting is then placed in a vessel containing water, the lower end is cut at a slant and pressed into the water; the upper part of the root, making at the bottom of the part so cut, a ledge whereon to rest the graft; this is recommended because the leaves being cut off, the graft should be placed on the side of the vessel where the water is to flow in and out, thus in the cutting fixed in its place while you tie it; next cut the scion sloping, to fit, and cut it so that a joint may be at the bottom of it, to rest on the aforesaid ledge; a union may be effected without the ledge, provided the graft can be well fixed, but the work will not then be so neat; moreover, the scion will occasionally put forth new roots from that lower joint; the stem is formed from the upper joint. I therefore procure the cuttings with the lower joints as near together as possible. After the graft has been tied, it is placed in a vessel, such as is used for room plants, as in is used for room plants, as in a close cupboard, to suit the climatic mode of the climate.

In about three weeks the scion will have put forth new roots from that lower joint; the stem is formed from the upper joint. If the surface the cutting with the two lower joints as near together as possible. After the graft has been tied, it is placed in a vessel, such as is used for room plants, as in is used for room plants, as in a close cupboard, to suit the climatic mode of the climate.

6335. By seed. The following directions are extracted from an excellent paper on this subject (Hort. Trans. vol. 255.) by Sabine. Collect the seeds in September from the dwarf plants, where no preference exists on other accounts, and from semi-double flowers when double varieties are chiefly desired. Perhaps seeds obtained from those particular florists of the disc which have altered their form, may have a greater tendency than others to produce plants with double flowers. Sow in March, or earlier, on a bed of 550° or 600°; the young plants to be pricked off, if necessary, in pots, and kept in a moderate temperature, saying class may be put by the scion, which may be absolutely necessary, that a joint should be at the end of the scion, for the scion will occasionally put forth new roots from that lower joint; the stem is formed from the upper joint. I therefore procure the cuttings with the two lower joints as near together as possible. After the graft has been tied, it is placed in a vessel, such as is used for room plants, as in is used for room plants, as in a close cupboard, to suit the climatic mode of the climate.

6357. Planting full-grown roots. These may either be planted on the spot where they are to flower, early in April, and protected by covering with litter or by empty pots, as in transplanting seedlings; or, when an early blow is wanted, they may be planted in large pots and forwarded in frames or pits, or in any spare house, with a temperature equal to that of the greenhouse, till the middle of May, when they may be brought in to the nursery to remain, and will flower in June. Sabine says, "Dahlias thrive best in rich loam, and a clear open space, neither sheltered by trees or walls. Like the potato, they exhaust the soil considerably, and do not thrive well when repeatedly planted on the same spot."

6358. General culture. No particular care is requisite after the plants are neatly tied to stakes; till they have been attacked by the frost, they should then be cut down and the roots covered with as much halm, old tan, or leaves, as would be necessary to keep the frost from the tubers of a potato-plant left in the ground. The soil is to be left as it is, and care is to be taken that it is well and regularly watered. But the most general way, especially with the valuable sorts, is to dig up the roots with a portion of the stem attached, and plant or bed them in pots or boxes among sand or dry mould, and keep them under the stage of a green-house, or in some dry airy place, free from the access of frost, till the spring, when a large scale, they may be planted in colleges, and covered with straw; the object being to keep them sufficiently moist and plump to maintain the living principle, and yet not to rot them, or have them destroyed by frost.
SUBSECT. 15. Auricula. — Primula Auricula, L. (Jac. Aus. 5. t. 415.) Pent. Monog. L. and Primulaeeae, B. P. Oreille d'ours, Fr.; Aurikel, Ger.; and Orecchio d'orso, Ital. (fig. 603.)

6339. The auricula is a flower of great beauty: it is a small fibrous-rooted plant, with fleshy succulent leaves, generally mealv on the edges; a native of the mountains of Switzerland, Austria, Syria, and the Caucasus, &c. We have gathered it in abundance near the post-house on the Simplon road. It was cultivated by Gerrard in 1597, under the name of bear's ears, or mountain cowslips. To show what cultivation may perform on this plant, Professor Martyn relates, from Morant's Colchester (1768, p. 92.), that Henry Stow, a gardener, near that place, a famous grower of auricas, had some plants with no less than 133 blossoms on one stem. About a hundred years ago the passion for this flower in England was much greater than at present; and, as Justice remarks, we supplied the Dutch, who afterwards, till the late war, used to rec-supply us with the progeny of our own flowers. Justice was the most enthusiastic cultivator of the auricula, and indeed of all florists' flowers of his time. After him the Lancashire growers are the next to be distinguished, and more especially Maddock, the well known author of the Florist's Directory, originally from Warrington. Emmerton is, at this time, one of the most enthusiastic admirers of this flower; and the best collections are to be found among the commercial gardeners near London, and the operative manufacturers and artisans near Manchester, Paisley, and other large towns. It is like the tulip, pink, &c., a poor man's flower, and a fine blow is rarely to be seen in the gardens of the nobility and gentry.

6340. The varieties are endless.

The colors of the flower in its wild state are yellow, purple, and variegated. Gerrard figures the yellow, purple, red, scarlet, bluish-colored, and bright-red, most of which grew in the London gardens in his time. Parkinson, in 1629, enumerates twenty varieties, and says many more were to be found. Rea, in 1709, has an increased number, classed as purples, reds, yellows, and whites. In 1792, the catalogue of J. Maddock contained nearly 500 named varieties, divided into ligioties, selves, or plain one-colored sorts, double flowers, and painted or variegated sorts. The latter only are held in esteem, and few collections contain more than two or three selves of the fundamental colors, and as many double flowers. Double varieties are not in esteem.

6341. Criterion of a fine variegated auricula. (fig. 603. a, b, c, d, e) "The stem should be strong, erect, and elastic, and of a proper height, that the bunch or truss may be above the foliage of the plant. The peduncles, or foot-stalks, of the flowers should also be strong and elastic, and of a proportional length to the size and quantity of the pips, which should not be less than seven in number, that the bunch may be rather round, close, and compact. The component parts of the pips are the tube (with its stamens and anthers); the eye; and the exterior circle containing the ground-color, with its edge or margin: these three should be all well proportioned, which will be the case if the diameter of the tube be one part, the eye three, and the whole pip six, or nearly so. All the admirers of this flower agree that the pips ought to be round; but this seldom happens; and we must be content if they are so nearly round as not to be what is termed starry. The anthers, or summits of the stamens, ought to be large, bold, and fill the tube well, and the tube should terminate rather above the eye; the eye should be very white, smooth, and round, without any cracks, and distinct from the ground or self-color. The ground-color should be bold and rich, and equal on every side of the eye, whether it be in one uniform circle, or in bright patches; it should be distinct at the eye, and only broken at the outward part into the edging; a fine black, purple, or bright coffee-color, contrast best with the eye; a rich blue or bright pink is pleasing, but a glowing scarlet or deep crimson would be most desirable, if well edged with a bright green; but this must seldom be expected. The green edge, or margin, is the principal cause of the variegated appearance in this flower; and it should be in proportion to the ground-color, i.e. about one half of each. The darker grounds are generally covered with a white powder, which seems necessary, as well as the white eye, to guard the flowers from the scorching heat of the sun's rays, which would soon destroy them if they were exposed to it."

6342. Propagation. By rooted slips, or dividing the root for continuing approved sorts, and by seed for obtaining new varieties. The best time for taking off slips, or dividing the root, is after the plant has done flowering and ripening its seed, if this last
is permitted. The operation is therefore generally performed in July and the beginning of August. Emmerton says, the Lancashire growers will not take off, or sell a slip before the 5th of August, on which day they begin to execute orders for young plants.

643. By seed. Maddock says, "the surest and best method to obtain fine auriculas from seed is to provide young, healthy, and strong plants, of capital high-colored sorts, possessing first-rate properties; these plants are to be freed from all stem, leaves, and cuticles, then placed, with a little sand, where they are exposed to the sun, air, and rain, when the last is in moderation; but if in excess, they should be preserved from it by mats or boards, or small hand-glasses may be placed over them. In dry weather, we must be on the watch for mouldy plants, for mould appears as it is a particular point." Emmerton is a warm advocate for raising the auricula from seeds, and says, any one who will follow his directions may be certain of raising very fine sorts. He selects the flowers he intends to breed from, according to the properties he desires in the offspring. Thus, he advises selecting those that have withstood the London and Manchester florists, and to plant them in pots; six plants of two sorts in each pot, viz.

For breeding light-green or grey-edged
seeds. A pot with 2 of Barlow’s king of
Barlow’s king and of Grimes’s privet; one
of Grimes’s privet and of Butterworth’s Lord Hood; one with
of Butterworth’s Lord Hood and of
yon’s ringleader.

For breeding light green or claret
green-edged seedlings. Pots with six plants in
each, viz. 3 of Barlow’s king, 3 of Pollet’s Highland boy; 3
of Barlow’s king, 5 of Buckley’s jolly
tar; 5 of Barlow’s king, 5 of War-
ris’s Prince Rochester; 5 of Strin’s
King; 5 of Strin’s Emperor Alex-
ander.

For breeding fine choice-litot-veined
green-ground seeded seedlings with green
eyes. Pots with six plants in each,
viz. 3 of Barlow’s superb; 3 of Fo-
don’s victory; 5 of Barlow’s superb;
3 of Barlows’s France Blucher; or 5
of Barlows’s France Blucher; 5 of
Bearless’s superb; 3 of Childe’s
king.

644. Each of these pots to be set apart, and at distance from all other auriculas, before the flowers have ripened, to prevent accidental contamination, and to be kept so detached till auriculas in general are ripened their seeds.

645. A simple mode is to impregnate the stigmas of one sort with the anthers of another, in Knight’s manner, or even without castrating the female parent. Nicol tried this last mode with the greatest suc-
cess both in the primula and dianthus genus. (Caled. Hort. Soc. Mem. iii. 273.)

646. The seed will commonly ripen in June and July, and is to be gathered in single capsules as it ripens, and kept in a cool, airy place, or in a box covering around it, according to Maddock; and from the middle of February to the 10th or 12th of March, according to Emmerton. Maddock says in boxes in
boxes, as lightly as possible, and sets the boxes in a hot-bed; preserving a moderate and equal degree of warmth both day and night, admitting fresh air occasional; this mode, he says, enables the plants to ripen as early as three weeks, if the warmth of the bed be properly kept up, whereas, by the usual mode of exposure to the open air, the greater part does not vegetate till the second year; and the weaker seeds, which are the most valuable, seldom vegetate at all.

647. Perfect mould must always be kept moderately moist, but never very wet; the best method of watering it is by means of a hard clothes-brush, dipped into soft water, which has had its chill taken off by standing in the sun, the hair side being quickly turned upwards, and the hand rubbed briskly over it, to cause the water to fly off in an opposite direction, in particles almost as fine as cress dew; a sufficient amount of moisture may, in this manner, be given in a few minutes. When the earth in the box is inclining to become mossy or muddy, it must be stirred all over very carefully with a pin, about as deep as the thick-
ness of a shaving. At the expiration of three, four, or at most, five weeks, the young plants will all make their appearance; it then becomes necessary to give them air by to render them fit for entire exposure to it, which they will be able to bear in a fortnight or three weeks afterwards, at which time the box should be taken out of the frame, and placed in rather a warm situa-
tion, though not too much exposed to the sun, till towards the end of April, when it may be again re-
moved to a cooler aspect, where it can only receive the sun till nine o’clock in the morning; and in May, when the heat is hot, it should be placed in the most cool and airy part of the garden, not neglecting, at any time, to keep the earth moderately moist; but at the same time preserving it from violent rains when-
ever they occur. As soon as any of the plants appear to be taken up with the compost, about an inch and a half or two inches asunder, and when they are again grown, so as nearly to touch each other, they may be a second time transferred into large boxes, or round small pots, at the distance of three or four inches, where they should now only happen to blow, which, properly having been in the sun, have acquired any considerable size; and then such as appear to be possessed of merit should be marked, and the inferior ones destroyed. As soon as the bloom is over, such as have been marked should be taken up, and planted separately in small pots, and be taken the same care of as other auriculas, till they grow a good size, and when time calls, to receive proper merits and properties may be ascertained with more accuracy.

Such weakly plants as are not able to blow the first or second year, ought nevertheless to be carefully pre-
served; for amongst these it often happens that the most valuable flowers are found. A great proportion of the seedlings, although the seed was saved from the best flowers, will be plain-colored or self, which, unless possessed of excellent properties in other respects, or being singularly beautiful in their colors, are of no value, but as common border-flowers.

638. Emmerton sons in small pots, about six inches over the top, and six deep, filled half full with coal-
ashes, and take a piece of draughting paper to cover the covers as thinly as possible with the auricula-compost, then puts on a bell-glass, and places the pots in a situation quite excluded from the sun, except in the morning. The bell-glass, he says, will cause the seed to vegetate much sooner, and by pouring the water over the top of it, the earth in which the seeds are placed will receive sufficient heat, but must be taken out from the rest of the bed. If it is not taken out, it, he says, would be a "very inconvenient." He thinks, "I would recommend the front of a green-house, or a cool-frame, for the seed-pots to be placed in, but by no means a hot-bed; or if not that accommodation, a hand-glass, having tiles or slates placed underneath, to keep the worms out of the pots; great care being taken to keep the moisture in the pots; or for five weeks, and three weeks, if in a green-house, the seeds will break ground; and when the leaves begin to appear, you must take care by degrees to admit air." After this, his treatment of the young plants till they flower is essentially the same as that recom-
mended above by Maddock. All pin-seed flowers, or such as are not of the stigmas and not the anthers, he recommends to be grown in the same ways or select sorts.

639. Hogg says, auricula-seed may be sown either in pots, or in the open air, about the 1st of March, and covered with a hand-glass. When the plants will bear transplanting, he removes them into pots of the smallest size, one in a pot.

6350. Soil. The different composites used by florists in growing this flower are almost as numerous, Hogg observes, as the florists themselves. "Persons often take extra-
dinary pains, and incur unnecessary expense, to injure, if not destroy, their flowers. Weak hands are soon misled by quackery and novelty, having no sound judgment of their
own; and quackery, even in the growing of flowers, has as many followers in as any other line." (Treatise, &c. p. 103.)

6351. Maddock recommends "one half rotten cow-dung, two years old. The cow-dung produced near London is more crude and gross to the country, occasioned by the difference of food on which the animals feed; it of course requires longer preparation and exposure to the atmosphere that the latter, but two years and a half will be found sufficient for it in its grossest and most crude state. One sixth fresh sound earth, of an open texture. One eighth earth of rotted and decayed leaves. One twentieth cow-dung, one twenty-fourth peaty or moorv earth. One twenty-fourth ashes of burnt vegetables." This compost is to be thoroughly incorporated and exposed to the air in an open situation for a year before it is made use of.

622. Emmerton says, "Good composting, the food, the very life of the auricula;" it must be very rich, and having early tempered and sweated over, when they contained the sun, frost, and air. His materials are goose or pigeon dung, night-soil, sugar-bakers’ scum, yellow loam, or loam from such land as will grow good crops of wheat, and sea-sand. He does not use salts of any kind, which, are, no doubt, supplied by the sugar-bakers’ scum, and that substance being cheap, gives it a decided advantage in that matter. His materials are, all of which he found success; in: some, night-soil and sand are wanting; thus: three barrowfuls of goose-dung, steeped in blood from butcher’s; three barrowfuls of sugar-bakers’ scum; two barrowfuls of fine yellow loam; or, two barrowfuls of goose-dung, steeped in blood of two barrowfuls of cow-dung, and two barrowfuls of fine yellow loam. These composts require two years’ preparation; in the first, they are mix up in a hole in the earth; and in the next, turned over every month in an open exposed situation, so as every part may be thoroughly frozen in winter, and heated by the sun and penetrated by the air in summer. Those composts, he says, he has used with the greatest success, though they have exhaust no sand. He next introduces that material thus: four barrowfuls of loam, steeped in night-soil and urine; two barrowfuls of goose-dung, mixed with blood; two barrowfuls of sugar-bakers’ scum; and two pecks of sand: or, two barrowfuls of night-soil; one barrowful of cow-dung; one quarter of fine yellow loam; two barrowfuls of goose-dung; two barrowfuls of cow-dung; two barrowfuls of fine yellow loam; and two pecks of sand. Great stress is laid on the blood, which, "when rotten down with other manure, does wonders beyond all idea;" but unless the above composts are well and thoroughly turn and mixed, they will not destroy your plants, and no doubt will nourish them. Rendered sweet and wholesome, it will be the means of throwing brilliant colors into the hips or petals, and of giving life and vigor to the plants, as much as fine old port or rich Madeira wine does to the human constitution." (Cult. of the Auricula, &c. p. 77.)

6354. The late P. Kenny, Hogan observes, "gardener by profession, was, perhaps, one of the most successful and eminent growers of auriculas in his day, and who won as many prizes as most men, during the course of ten or twelve years that he lived at Totteridge, in Middlesex. He certainly had all the benefit of air, situation, and in his hands the readiness for the flower, and his skillful treatment of it, (against nothing of his being almost constantly in the garden,) gave him a decided superiority over many of his competitors, and ensured, as it were, his success. He always kept by him a quantity of sound staple loam, of rather a sandy nature; this has been turned, by frequent turning. His next principal ingredient, is that, containing cow-dung and hay-litter, obtained from the sheds used to rear early lambs, well rotted, by being turned, mixed, and fermented in the same manner as the gardener does horse-dung and straw-litter. His proportions were this: one third loam; two thirds sheep-dung and hay-litter; one tenth coarse sand. These formed his compost for growing equal parts of coarse sand and earth; and, if he had always been so careful in the quality, if possible, (which he sometimes was not,) to be used to top-dress his plants, and this he would sometimes do twice in the year. When they killed any sheep, he always reserved the blood, and mixed it with the dung of poultry. These two ingredients he added to his loam and sheep-dung, and these constituted his compost for surface-dressing."

6356. Curtis, in a note to the last edition of Maddock’s work, says, “We have seen the strongest auriculas produced from the following ingredients: two thirds of the dung and sand from old hot-beds reduced to fine powder, one third of cow-dung from old hot-beds reduced to fine powder, one eighth earth of coarse sand and peat or bog earth, such as is used in the curing of hares, mixed well together by sifting or screening, and suffered to be well aired by frequent turnings during the frosts of winter.” (Florist’s Direct. 101.)

6357. Henderson, of Delvin, uses two parts of very rotten dung, one part from old hot-beds, one part of vegetable mould, one quarter of river sand, mixing the whole, and exposing it for a winter. (Caled. Hort. Soc. Mem. ii. 230.)

6358. The compost in most general use among auricula-growers is of fresh loamy soil and perfectly decomposed cow-dung, equal parts, and adding one eight part of the mixture of sea or river sand. Some use leafmould instead of cow-dung. The whole incorporated and prepared for one summer and one winter in the usual manner.

6359. Manner of growing. The common sorts are grown in beds or in mingen borders; but all the fine flowers in pots. Maddock recommends pots of six inches and a half interior diameter at top, seven inches deep, and the interior bottom diameter four inches, for full-grown flowering plants; and smaller sizes for seedlings and newly separated offsets. Emmerton uses pots for large blooming plants, eight inches high, five inches and a half diameter at the top, and four inches and a half at the bottom outside measure.

6360. Time of potting and transplanting full-grown plants. The most advisable time to pot auriculas, according to Maddocks, is immediately, or soon after bloom, and
this should be repeated annually (notwithstanding the opinion of some who say the plants bloom better the second year after potting) for this obvious reason, that it preserves the health and constitution of the plants, by affording them a fresh supply of nutrition; and at the same time the cultivator has an opportunity of curtailing their fibres, if grown very long, or of cutting off the lower part of the main root, if too long, or the end of it, if decayed; thereby forcing the plants, as it were, into a state of action, and causing a continued circulation of their juices, during the summer, in the formation of new fibres for their necessary sustenance and support: whereas, if this operation of potting is not performed till the second year, the soil must have lost a considerable part of its nutritious quality, which will produce a proportionate decline in the strength of the plants; and if it be deferred till the autumn, there will not be time for a sufficient reproduction of the fibres before winter sets in, the effects of which will be a faint-colored and weak bloom the ensuing spring. The only objection of any importance, against spring potting, is that some sorts will in consequence be more inclined to blow in the following autumn, and thereby deprive the plant of its capacity to bloom well the ensuing spring; this, however, occurs but in few instances.

6361. In potting or transplanting auriculas, the plants should be carefully turned out of the former pot, and the earth shaken from its fibres, which should be curtained if found too long and numerous, together with the lower end of the main root, and the fibres attached to that part, if it appears too long, or some what decayed; the plant is to be at the same time carefully examined, and wherever any unsoundness appears, it must be entirely eradicated by means of a sharp penknife, let the extent of it be ever so great, till no appearance of decay remains; the plant then placed nearly in the same position as before, but, or as the sailors phrase it, betwixt wind and water, which, being alternately wet and dry, is more subject to decay than any other part, and for the same reason is the most difficult to heal: the wounded part should be immediately exposed to the sun, and when the surface of the wound is perfectly dry, the wounds' wax should be applied, consisting of one part of bees' wax, and two parts of fine sand, softened in the sun, or by a fire, to make it adhere more firmly on application; this will become close and hard when cold, it will resist moisture, and is the best application yet discovered, to prevent further progress of the decay. Whenever the lower part of the surface consisting of a carton of earth, below the place where it is to be set, gets dry, it is proper to steep it off, in a direction downwards. On replanting, a pot suitable to the size of the plant is to be selected; it is to have a hollow oyster-shell placed with its convex side upwards, over the hole at the bottom, and then to be about three parts filled with compost, higher in the middle than at the sides; the plant is next to be placed therein, with its fibres regularly distributed all round, so nearly or quite as to reach the sides of the pot, which is afterwards to be filled up with the compost, adding a little clean coarse sand close round the stem of the plant, on the surface: the bottom of the pot should then be gently struck two or three times against the table, which is supposed to be made use of for the sake of convenience in the operation, in order to render the soil more firm and compact; this will cause it to sink or subside about half an inch below the top of the pot, which will prevent the loss of water when it is administered.

6362. The true depth to plant an auricula is within about half an inch of the bottom of its lowest or outside leaves; as the new and most valuable fibres proceed from that part, so they should immediately meet with earth to strike into, or otherwise they will perish: it will likewise encourage the offsets, if there be any, to strike root sooner than they would do if not in contact with the soil. (Florist's Direct. 12d.)

6363. On the foregoing directions, by Maddock, his editor, Curtis, has the following note: "Notwithstanding the author has so particularly recommended the annual fresh potting of auriculas, we must beg leave to differ in opinion from him, as far as relates to those plants which are intended to bloom strongly the following spring, the mode of potting advised being to shake the whole of the earth from amongst the fibres of the plant, in order to examine the lower end of the main root, this severe operation being performed in the spring, when the plants ought to be making their most luxuriant growth, will have evil consequences. Simply to this, the plant being firmly established, nature intends its greatest growth and productivity the following spring; during this rapid growth, the operation gives an unnatural shock to vegetation; the consequence is, the plant must remain dormant until fresh fibres are formed sufficient to draw nourishment for supporting the growth necessary to form a strong blooming plant. Having given our opinion upon this point, we would recommend to the reader, when selecting plants intended for strong blooms the following spring from the younger ones, turn them out with their balls of earth entire, and if the fibres are healthy, return the balls into a set of pots one size larger than they were in before, adding new compost to fill up: we have no objection to remove as much earth as can be done without disturbing the mass of fibres; in this state treat them as usual, and when those which have bloomed strongly on this plan are out of bloom, put them on the plan recommended by the author. We beg leave also to notice, that it sometimes happens that the oyster-shell placed at the bottom of the pot by fitting too close confines the water in it, which is inseparable from the covering of the plant; we would advise the collector to be taken for the efficient drainage of a superabundance of wet, by putting two or three pieces of broken pot over the surface of the bottom."

6364. Emmerton disapproves both of spring and autumn transplanting, and says, "the best time for the operation is soon after they are out of bloom; say about the 22d or 23d of May;" but he adds—

6365. From the 29th of May to the 12th of June, I have transplanted my flowers with great success, even as late as the 13th of July. On no account remove a general collection a week later, at least, those you intend to bloom very strongly: by this means they will have three or four months to get well rooted before winter, which they ought to have; and if you transplant them early in the spring, it will be so favourable for the growing, that the plants will increase twice as much as if planted later. Strong-blowing roots should not be removed more than once in two years; to do it oftener would be to run a risk of not having any fine flowers to exhibit on your stage; because these plants never thrive riggh till the roots have reached the sides of the pots, and it seldom, if ever, happens that they get sufficiently well established in a full-sized auricula-pot, in one year. By no means remove your large-blooming auricula-plants in dry hot weather, as by shaking the mould clean out the plant the roots will not freely draw fresh fibres, except the weather is inclined to be showery, and what is termed a cool moist air. I find the best chance in early weather, or in rainy weather, or when the young plants have reached the bottom of the pots, which should be slipped out of the pot with the whole ball of earth, and then immediately planted in a full-sized blooming pot for the ensuing season; in this last case I used to pay no attention whatever to the dry weather. If your large-blooming plants have not been removed for two or three years, their

31
small roots will have filled the pots, and probably their large, or what is called by some the carrot root, may be grown so long as to support shortening; in this case the plant must be taken out of the pot, and the earth entirely shaken from it; you will see what is necessary to be done; shorten the carrot-root, if necessary, for if you suffer it to remain too long, it will either get rotten at the end, and always keep the pot closed, or especially if the pot be large, it will want shifting every year, and never produce fine strong flowers. Reduce their small roots to about ten or a dozen, leaving those that are nearest the leaves; they will be sufficient again to support and vegetate your plant. If you perceive any canker or rottenness in the root, cut it boldly to the quick, till it appears healthy and live. The Earth consists of a little mastic, bees' wax, turpentine, and white rosin, in equal parts, to heal and dry them; leaving as many fibres to it as possible. If a large-blooming plant, or any other one you remove, has been in the pot but one year since it was transplanted, you may slip it out of the pot, but if its fibres may have reached the outside, they will not be so large and numerous, or so matted together, as the older plants that have remained in one pot two clear years. You need not therefore shake the earth from it, but with a sharp knife cut the fibres and earth away till you reduce it to the size of a cricket-ball, or rather larger, as much depends on the size and air of the potting-sauce. 

**Treatise.**

6366. Hogg recommends the first week in August, because *if you put your plants at this early period of the season into pots, in which they are to remain till they flower again next spring, the space of nearly twelve months, the strength of the plants must be greatly reduced before that time, particularly if the plants are set in large pots to strike fresh fibres, and to get well established in the pots, before winter; and, with the return of spring, you may expect a vigorous growth of the plant in all its parts. The customary mode is, to shake the mould completely from the roots every second year; but, in doing this, you must be guided by the condition of your plants. If their roots are weak and very thin, the third year, reducing the ball of earth only, the fibres, and examining the carrot or main root. Transplanting should be done in a cloudy sky and a moist atmosphere*. 

6607. Justice pots suckers, and transplants old plants, in August. Henderson, of Delvine, says, *the last week in July, or the first week of August, if the plants have done flowering. At that season, I shake the mould from the old plants, and cut the end of the stump up to the fresh young roots, if it has grown too long. (I am now speaking of those plants which have been in the largest pots, for four or five years.) Afterwards, I fill the wounds with gum-mastic, to prevent evaporation, the plants are re-potted in the second set of pots. Next May they are shifted, with the ball entire, into the largest size, or flowering-pots; so that from the first potting of the young plants in small pots, to a complete shifting, four years elapses; the plants having been one year in small pots, one in the second size, and the third size is put in; the fourth year is spent in the little pots. If any wounds are made by taking off the suckers, they are dressed with mastic. At all times the stems are cleared of sprouts above ground as they appear, but suckers from under are allowed to grow, in order to form young plants.*

**Caled. Hort. Soc. iii. 539.**

6608. *Shrubs and Potting-off of Old Plants.* When offshoots have formed one or more fibres, an inch or two in length, Maddock directs to remove them by means of a piece of hard wood, or by the use of the fingers, to be separated from the old plant with safety, and replanted round the sides of a small pot, filled with the same compost, till they become sufficiently grown to occupy pots separately; if a small hand-glass is placed round them, the experiments appear to me quite conclusive in favor of late potting. The slips or offshoots will also have acquired more strength and better roots, by being suffered to adhere to the parent plant till the beginning of August, and will occasion you less trouble in protecting and sheltering them. From the beginning of August, the beginning of November is a period quite long enough for the plants to strike fresh fibres, and to get well established in the pots, before winter; and, with the return of spring, you may expect a vigorous growth of the plant in all its parts. The customary mode is, to shake the mould completely from the roots every second year; but, in doing this, you must be guided by the condition of your plants. If their roots are weak and very thin, the third year, reducing the ball of earth only, the fibres, and examining the carrot or main root. Transplanting should be done in a cloudy sky and a moist atmosphere*. 

6609. Emerson says, *You may separate offshoots from the mother plant any time between February and August, according as they are in size, or are wanted for increase, and plant them immediately against the side of pots four or five inches in diameter. If a strong and superior bloom of flowers is desired, no offshoots must be allowed to grow on the old plant, and especially none on the stem without fibres. If they are small, you can use them without the size of hemp-seed.*

**Treatise on the Auricula, &c. 139.**

6670. General culture. Maddock keeps his auriculas during one part of the year in what he calls a summer repository (fig. 604.), and the other in a winter repository. **Treatise.**

6721. Summer repository. The following is recommended as a proper plan for the summer repository, viz. in the first place, there should be a bed of coal-ashes formed in the place where it is intended to be, about five or six inches thick; or a platform of plain square tiles, closely fitted to each other, on the surface of the ground, to preserve the pots from the common earth-water, by admitting the water at the sides, and on, would permeate, and alter the consistence of the soil, in such a manner as to prove very injurious; upon this foundation, rows (fig. 634.) are to be placed in straight lines, about two or three inches asunder, which will allow for a free circulation of air under and between the pots when placed upon them, an object of great importance, especially in warm weather, when the air is most inclined to stagnate and become impregnated with noxious effluvia. The plants, by the above plan, will be raised from nine to twelve inches above the level of the ashes or platform. There should be two rows of substantial stakes, three feet long, and five inches by three wide, one row of which should be placed on each side, at about three or four inches distance from the other two rows. These stakes (c) should be driven twenty inches into the ground, with their narrow sides towards the pots, and have no roots cut in their tops, restored the edges of the shutters they are intended to support. By way of illustration, suppose the whole length of the platform to be twelve yards, and the width three feet, it will contain seven rows, and each row about four pots, and two stakes; this amount of ground constitutes a moderate collection for a private gentleman. Three shutters (f), made with feather-edged inch-deal boards, each four yards long, and two feet six inches wide, will reach the whole length on one side: three of the noticed stakes will be sufficient to support these shutters; of course, fifteen stakes at proper distances will completely answer the purposes on one side: the notches are to be cut in the form of a V, two inches deep and three inches wide at the
AURICULA.

...these it but if... of form advantage the whether and, this provides of the proper height and strength, should proceed from the ground between the two middle rows of pots, to support the shatters when closed or closing, especially as it is usually more convenient to begin to cover or uncover on one side first, and finish on the other; without a support of this kind, in such circumstances as it is most full, the plant is necessary on each side, to support the shatters when open, with the same degree of slope, in a contrary direction than when closed; by which means the plants will have a free communication with the air, which is so essential to any height or excessive degree of temperature, the lower edge of the shatters is as high or higher than the top of the plants at all times. The peculiar advantage arising from this plan is, that when the plants require to be shut up from excess of rain, they have at the same time the advantage of a continual supply and free circulation of fresh air, which passes amongst the different shatters which those who have to exclude excess of rain from them, oftentimes shut them up in a wet state, as soon as it is judged they have had a sufficiency: this is a very dangerous, though not unusual practice, and often produces a mildew which is so fatal to auriculas. When of such consequence, or necessary, and suitable treatment of the plants, for the summer season, will sufficiently apologise for any proximity in the description: it cannot, indeed, be too strongly impressed on the mind of the cultivator of this delicate flower that his success more particularly depends on the health and vigor of his plants towards those larger pips, of whatever other natural color they are, the repository, are to be kept moderately moist; if the rains that happen are not sufficient, they must be occasionally watered with soft water, by a small pot with a round curved spout, taking care not to let any water fall into the heart or amongst the interior leaves of the plant, as it could not speedy dry in that part, and, of course, would endanger a decay; any water lodging in the heart of the plants in spring, when the blossoms begin to make their appearance, cannot fail to injure them considerably. The plants are to remain in their summer situation till September or October, as the weather may be more or less favorable, or the sun has so decreased its heat..."
the bricks are removed, and the frames rest on the ground. In all dry and temperate weather the plants are left, and only watered when necessary. If the plants are kept indoors, and the temperature and humidity of the room are moderate, the plants may be put outdoors in a dry shady place for short periods, without injuries. The pots are placed to the rim in sawdust or coal-ashes. (Hogg.)

679. Justice places his auriculas in what he calls a bunker or shed, on the 10th of October. This bunker is a stage with boarded ends, front and cover, placed against a wall with a north-eastern exposure. He gives these a south exposition by the end of December; he confines the plants, and if they are weak he adds the proportion of one eighth of fullers' earth to the compost.

680. Blooming-stage. (fig. 605.) This, according to Maddock, should have a northern aspect, that the sun may not shine directly on the tops of the frames, in the form of steps, but must not exceed five times the horizontal and lower than the first, and the rest in the same proportion; these shelves should be about six inches wide, and length, and well supported, otherwise the weight of the pots will cause them to bend or fall. If the stage consists of a series of shelves, its depth, from front to back, ought to be about two feet eight inches; the north or front elevation of the stage should not be less than seven feet, gradually sloping to about five feet six inches; the shelves could consist of frames of glass. The frames of glass made use of on the south side of the winter repository will answer extremely well for this purpose, but are too wide to form the roof completely, without addition, a single row of feather-edged boards may be placed on the lowest part of the slope, and the lower edge of the frames of glass may rest upon them; these boards will answer another good purpose, by preventing the sun, if this season of the year has obtained a considerable degree of altitude, from shining on the tops of the plants which it has made the middle of the day; as it has made, in the plants of the back row will, in consequence, have rather less light, yet it is not so materially injurious as the former. The posts supporting the roof of the stage, on the south side, may be so constructed, and placed at such distances from each other, that the wooden shutters, made use of on the north side of the stage, can perform a regular ventilation, and close at a moment's notice; the shelf: the remaining space to the ground may be left open in mild calm weather, or may be easily closed up, by a line of mats sewed together, when it is otherwise. The east and west ends of the stage should be entirely boarded up during the winter; the front left open, unless in unfavorable weather, and at night; the times, it may be defended by frames of wood covered with canvas: these should be about six feet wide, suspended from the front edge of the roof by hinges; they will serve both to defend the bloom, when let down, and also by each having two small iron rods, about five feet six inches long, connected above by a rod, allow them to move in any direction, and support them when up, will defend the path in front from rain, take off the glare of light when the sun shines, and at the same time defend the spectators from its heat. The inside of the back and ends of the stage, and the shelves likewise, should be painted black, or some very dark color, by way of contrast to the white edge of glass, and if a second stage be placed at each end of the stage, the effect produced will be very pleasing, and apparently lengthening the stage each way as far as the eye can reach.

681. As auriculas and hyacinths generally blow exactly at the same time, the beauty and elegance of the scene is considerably increased by having a stage of the former, and a bed of the latter, under the same roof. The stage of the auriculas is made twice as wide; in which case, if the cloth covering of the hyacinths is fine enough to admit a sufficiency of light, it may be continued over the auricula-stage, instead of the glass and boards, and will answer all purposes tolerably well with little trouble: or otherwise, the edges of the cloth may be nailed on, or upon the upper only of the frames, over the auriculas, in such manner as effectually to prevent rain dripping through in that quarter. A row of fine polyanthuses, in pots, may likewise be introduced in front of the hyacinths, as they likewise blow at the same time; it will add to the variety, and form altogether a more elegant assemblage or border of plants of the year can afford. The tulips blowing auriculas should stand on the last or most distant shelf, and the shortest in front; those stems which are weak and bend should be supported with small wires, fixed in the earth behind them, so as not to be easily discerned. If any of the stems and blossoms of those in the back row incline forward too much towards the light, they may be easily recovered to an erect position, by turning the pots for a few hours in the morning; but the glass roof will render very little of this trouble necessary: the pots must be regularly watered, two or three times every week, during the bloom. No person can depend on a complete stage of auriculas, who is not provided in autumn or early in the spring with twice as many blooming plants as his stage will contain, because some will eventually prove defective, and fail in one respect or other: and a succession of proper plants in bloom will be required to replace such as, being earlier than the rest or of shorter duration, are no longer eligible to remain on the stage, and ought, in consequence, to be taken away, and replaced by suitable ones as their stead.

682. When the bloom is declined, the plants are to be removed into their summer repository, where they will soon recover their former strength and vigour, which, notwithstanding the utmost care and precaution, will have been, in some degree, impaired by standing two or three weeks upon the stage: and in consequence it is necessary that they should be put to blooming again as soon as possible, viz. to use the language of a florist, to prevent them from being set, all trouble and danger will be completely over. This strict care commences about the 20th or 22d of March, and ends, as I calculate, by the 8th of April, or the 9th thereof. Among the choicest sorts have always been spilt by nursing them as they do their geraniums, that is, by keeping their plants under glass so many weeks, night and day. Many florists keep their lights continually over their flowers, day as well as night, from the 1st of January till the 1st of May, and only admit a current of air at night, and this is fatal to the flowers, which so many split on. This mode of treatment, I am convinced, is highly improper; it draws up the flower-stem, and renders it weak and spindle, in a state unfit to bear or produce a bold truss. To bloom an auricula in perfection, it does not require to be kept longer than twenty-four days, or thereabouts; as a criterion, say from the 4th to the 20th of April; you will find your middle pipe expanded, or nearly so, and well adapted to be exhibited on the stage at this time. Previously to this period, however, say from the 10th to the 16th of April, he removes them from the frames (which have a south aspect), and places them under hand-glasses in a full or north-eastern exposure. Here they remain till the 20th or 22d of April, and are then removed to the stage in a full north aspect.

684. Hogg keeps the lights over his auriculas, in April, night and day, to preserve their beauty unimpaired. Air he admits by raising the ashes behind; he covers up close at night, "this being the very crisis of
time that requires your most particular care." He thins out the pips or blossoms, leaving not more than thirteen, nor fewer than seven on a truss or umbel. In thinning, "they should be taken out two or three at a time, and it requires some taste, nicety, and art, to perform this operation well, that the blossoms which are left on may grow in a regular tridentant form, so that any common spectator might suppose that no such thinning of the pips had taken place, but that they had grown exactly in that form, and with that number, from the first." Towards the end of the month the flowers are removed to the stage fronting the east.

6383. The Lancashire growers, "in blooming time, set their large show-plants under hand-glasses, in an east aspect, to receive the morning sun only. The plants are, perhaps, not so early in bloom as those wintered in frames, but when their stems are not drawn, and they are able to support the trusses firmly: the mildew and rot do not take them so readily as when in closer situations."

6386. Justice blows his flowers in the bunkers, or sheds, exposed to the full north; he gives them the air he can, but excludes the sun, shelters them from winds, and waters them well twice a week. (Brit. Gard. Direct. art. Auricula.)

6387. Henderson, of Delvine, blows his flowers in a frame (fig. 606.), which he says, "answers all the purposes of frame, hand-glass, and stage, used by the English florists; at least I make it do so. I have only to erect a screen of matting or poles in front, during the flowering season. The plan of it (a) is a long hexagon, which has a span roof b) and a low stage sloping on all sides. (c) In the elevation are eight ventilators (d), eight hinged sashes (e), and as many iron rods on staples for holding them up (f)." The whole seems a simple, economical, and sufficiently neat structure.

Subsect. 16. Primula, or Primrose Family.—Primula, L. Pentand. Monog. L. and Primulaceæ, B. P. 6388. The primrose family, grown as florists' flowers, consists of the polyanthus, primrose, cowslip, and oxlip.

6389. The polyanthus is the Primula vulgaris, var. Polyanthus, L. Primula, French, German, and Italian. In its wild state, the common primrose is too well known to require any description, it produces its flowers on numerous peduncles; but, by cultivation, throws up a scape, bearing an umbel of numerous flowers, brown, purple, red, and yellow. Linnaeus asserts, that the peduncles in the common wild primroses spring from a scape, which being so short as to be concealed among the leaves, has not been observed. Curtis, however, found it in a few plants, and also that wild primroses, introduced into Dr. Buxton's garden, at Maize Hill, near Greenwich, produced flowers both with and without a scape, and became, color excepted, perfect polyanthuses. Many botanists consider, that the polyanthus, primrose, cowslip, and oxlip are one species; and the Rev. W. Herbert seems to have proved it, and the same thing as to Primula auricula, helvetica, nivalis, and viscosa. (Hort. Trans. iv. 19.) It is sufficient for our purpose to observe, that the polyanthus is a very permanent variety, which does not readily return to the primrose, and that it is in high repute as a select and border flower, appearing in March and April, when there are few others to decorate the flower-garden.

6390. Varieties. These are as numerous as the varieties of auricula; and, as in that plant, single flowers are most esteemed.

6391. Criterion of a fine polyanthus. "Its properties are, in most respects, similar to those of a fine auricula, viz. the stem, peduncles, or foot-stalks, and formation of the bunch or truss; therefore, a definition of its pips, or petals (fig. 607. a), only remain necessary to be considered in this place. The tube of the corolla above the calyx, should be short, well filled with the anthers or summits of the stamens, and terminate fluted, rather above the eye. The eye should be round, of a bright clear yellow, and distinct from the ground-color; the proportion as in the auricula throughout the flower. The ground-color is most admired when shaded with a light and dark rich crimson, resembling velvet, with one mark or stripe in the centre of each division of the limb, bold and distinct, from the edging down to the eye, where it should terminate in a fine point. The pips should be large, quite flat, and as round as may be, consistent with their peculiar beautiful figure, which is circular, excepting those small indentures between each division of the limb, which divide it into five or six heart-like segments. The edging should resemble a bright gold lace, bold, clear, and distinct, and so nearly of the same color as the eye and stripes are scarcely to be distinguished; in short, the polyanthus should possess a graceful elegance of form, a richness of coloring, and symmetry of parts, not to be found united in any other flower." (Maddick.)

6392. Propagation. By dividing the root, or by slips, for ordinary purposes; and by seed, for obtaining new varieties. 
6338. By seed. The plants from which seed is to be saved are to be separated from the stems, and treated in the same manner as seed-bearing auriculas. When ripe, it should be cut off with part of the stem, and so preserved till the sowing season, which, as well as the mode of procedure, are, according to Madow, the same as for auriculas. Crampton says, flowers intended for seed should be selected on the same principle as he directs for the auriculas; and he recommends Pearson's Alexander and Nicholas's Tantara as excellent flowers to breed from. Knight's mode of castration may be adopted.

6339. Justice, he has had great success in raising polyanthuses and primroses from seed. He gathered seed the 28th of June, and sowed it ten days afterwards in boxes, placed in the open air, under a wall or hedge with a north aspect. In July, he directs to prepare a nursery-bed of the same earth in which they were sown, and plant them carefully out, taking up as much earth about their roots as you can, so as not to disturb their young fibres, planting them two inches sandier, and shading them from the sun until they have struck new roots; keep them clear from weeds, and give them gentle waterings, and let this nursery-bed be made in such a situation as to have the morning sun only. Some of them will show their flowers the same autumn, and many of them in the spring following. Select the best of these in a bed planted in a shady spot in November, and set them in the plants, which will greatly strengthen them for the succeeding spring. They require to be transplanted every two years." (Brit. Gard. Direct. 218.)

6340. Seed. Maddock and Emmerton recommend the same compost as for auriculas, but with more loam. Maddock used the following: "to one load of well rotted cow-dung, or leaves of trees, take half a load of fine white sand, and two loads of fine hazely loam, taken from a pasture some months before, and which has had the sword rotted amongst the earth: mix all well together before using."

6341. Hall, the primrose and polyanthus require a much hotter portion of sandy loam than the auricula, a very small quantity of rotten dung, and a little leaf-mould or heath or peat earth, mixed with them: in this they are found to grow extremely well."

6342. Manure of growing. Maddock says, they may be grown in the same sized pots as the auricula, and be treated in the same manner; but as they are more impatient of heat and drought, and partial to shade and moisture, they may, with equal propriety, be planted on cool and shady beds or borders. This is the general practice of almost all the growers of this flower.

6343. General culture. The polyanthus is very hardy, and seldom perishes in the coldest and wettest seasons, but when the heat of summer, the heaths, the greenfly, the white and red spider. "This insect," Maddock observes, "seldom attack plants as are in a state of vigor, or when the weather is cold and wet; it generally commences its depredations in the early part of summer, and continues its course and devastation of all plants of a more viscid and saccharine structure, till it becomes the most vicious and saccharine, afford it more suitable nourishment than at any other season. Such plants as appear infected should be immediately selected from the rest, taken out of the earth, and soaked for two or three hours in a strong infusion of tobacco-water, and be replanted in a fresh soil or compost, and removed to another situation remote from the former. If the whole bed or border of polyanthuses is overrun with this insect, it is best to take up all the plants, serve them in the same manner, and plant them elsewhere. The bed or border from whence they have been taken, should be immediately dug up or trenched, and suffered to remain fallow till the following season, or be occupied with some crop not liable to the same calamity."

6344. The primrose (P. vulgaris, L. (Eng. Bot. 4.) Primula, Fr.; Shafloose Primula, Ger.; and Primaver, Ital.) (fig. 607.) has a perennial root, appearing as if bit off at the end, with a singular smell like that of the anise. It is a native of most parts of Europe, in woods, coppices, and sheltered lanes, particularly in a clayey soil. The flowers of the wild plant are almost always of a brimstone-color, but sometimes of a purple hue; they appear in March and April.

6400. Varieties. The double varieties produced by culture are in most esteem, of which there are —

6401. The cowslip (P. veris, L. (Eng. Bot. 5.) Primula, Fr. and Schlusselblume, Ger.) (fig. 608.) is distinguished from the primrose, by smelling more strongly of anise, by shorter leaves, and by an umbel with a leafy involucre. It is a native plant, and found in moist pastures, in open situations, flowering in May.

6402. Varieties. Both double and single varieties are in esteem; but the plant has not been so much cultivated as the primrose. Gibbs, nurseryman, Brompton, has lately raised a great many very beautiful varieties from products of the wild cowslip, which have sported into varieties, and by frequent reproduction, have attained their present excellence. The changes that have taken place are in the magnitude of the trusses, and the size and color of the flowers; appearing to have been made from the darker hues, though some paler flowers were in the collection. However great the variation was in the points alluded to, yet none of the specimens appeared to have lost the general character and appearance of cowslip, not running either into the wild cowslip or the primrose; but some of them have become what florists term hose-in-hose, which appears to be the conversion, more or less, of the calyx, into the appearance of the corolla."

6403. The oxlip (P. elatior, L. (Eng. Bot. 518.) Pavillon, Fr. and Gartenprimel, Ger.) (fig. 609) is distinguished from the primrose by its many-flowered scape,
6406. The carnation is little known in its wild state, though it has been found in England on rocks and walls. It was unknown to the ancients in its cultivated state; but has been a favorite flower in Europe for an unknown length of time. It is generally supposed to have been introduced from Germany or Italy, in which countries it is more cultivated than in England; Gerrard, in 1597, received it from Poland.

“Of all the flowers that adorn the garden,” Hogg observes, “whether they charm the eye by their beauty, or regale the sense of smelling by their fragrance, the carnation may be justly said to hold the first rank. The stateliness of its growth, the brilliancy and diversity of its colors, and the sweetness of its perfume, never fail to attract our regard and admiration. The tulip, though styled the queen of the garden, cannot boast of more admirers: they may with propriety be considered the two master-pieces of nature; and, though rival beauties, may be said to share the sovereignty of the garden equally between them. Yet it must be admitted, that the carnation, independent of its fragrance, has this advantage over its rival, that it continues longer in bloom; and that when planted in pots, it can be removed to decorate the green-house, the conservatory, or the drawing-room.”

6407. Varieties. Parkinson (in 1629) has forty-nine sorts, which he divides into carnations, or “the greatest sorts in leaf, and flower,” and bed-flower, or such smaller sorts, as flowers, or buds, are called. As flag is called, in Westminster, the most remarkable man at that time for the culture of these flowers. Rea (in 1702) has 360 good sorts of carnation; a number scarcely exceeded by the catalogues of modern British florists.

The varieties of this flower are now arranged in three classes: flaxes, bizarres, and picotées. Flaxes have two colors only, and their stripes large, going quite through the leaves; Bizarres (Fr. odd. irreg.) are variegated in irregular spots and stripes, and with not less than three colors: Picoétes (Fr. pièneilles, pricked or spotted) have a white ground, spotted or pounced with scarlet, red, purple, or other colors. Of each class there are numerous varieties, arranged under the farther subdivisions of scarlet flake, pink flake, purple flake, yellow flake, &c. scarlet bizzare, crimson bizzare, &c. and purple picotée, yellow picotée, &c. Hogg gives a catalogue of nearly 350 sorts, so arranged, named after great personages, all of which were in his possession at the time he published his Treatise on the Carnation, in 1620. Only double varieties are in esteem. As an oddity may be mentioned the double dwarf carnation of Leige, with sessile flowers.

6408. Criterion of a fine double carnation. (fig. 610, c and d) “The stem should be strong, tall, and straight; not less than thirty or more than forty-five inches high; the foot-stalks, supporting the flowers, should be strong, elastic, and of a proportionate length. The flower, or corolla, should be at least three inches in diameter, consisting of a great number of large well formed petals; but neither so many as to give it too crowded an appearance, nor so few as to make it appear too thin and empty. The petals should be long, broad, and substance, particularly those of the lower or outer circle, commonly called the guard-leaves; these should rise perpendicularly, about half an inch above the calyx, and then turn off gracefully, in a horizontal direction, supporting the interior petals, and altogether forming a convex, and nearly hemispherical corolla. The interior petals should rather decrease in size, as they approach the centre of the flower, which should be well filled with them. The petals should be regularly disposed alike on every side, imbricating each other in such a manner as that both their respective and united beauties may captivate the eye at the same instant: they should be nearly flat, however a small degree of concavity, or inflection, is, or broad, or flat, and is allowable; but their edges should be perfectly entire, that is to say, free from notch, fringe, or indention. The calyx should be at least one inch in length, terminating with broad points, sufficiently strong to hold the narrow bases of the petals, in a close and circular body. Whether the colors of the flower, or colors in the flowers, should be perfectly distinct, and disposed in long regular stripes, broadest at the edge of the lamina, and gradually becoming narrower as they approach the unguis, or base of the petal, there terminating in a fine point. Each petal should have a due proportion of white, i. e. one half, or nearly so, which should be perfectly clear, and free from spots. Bizarres, or such sorts with two colors in the same ground, are esteemed rather preferable to flaxes, which have but one, especially when their colors are remarkably rich, and very regularly distributed. Scarlet, purple, and pink, are the three colors most predominant in the carnation; the two first are seldom to be met with in the same flower, but the two last are very frequently. When the scar-
let predominates, and is united with a paler color, or, as it sometimes happens, with a very deep purple upon a white ground, it constitutes a scarlet bizarre, of which there are many shades and varieties, some rich and others pale, as is the case with all the rest. Pink bizzars are so called when the pink abounds; purple bizzars, when the purple abounds; crimson bizzars consist of a deep purple and rich pink. When the pink shade is very high in color, it is distinguished by the appellation of rose bizar; but some are so nearly in the medium between a pink and a scarlet, that it can scarcely be defined to which class they belong. In addition to the foregoing varieties, there is also held in great estimation by some nurseries the so-called picotè (fig. 611 a); many of which are very beautiful, and being harder than the other sorts, are in considerable request. The colors are principally yellow, and white spotted; these properties are the same as the other kinds, except that the edges of the petals are serrated or jagged, and the color is disposed in spots, where the others are striped. It is propagated in the same manner as the others.

6410. By layers. The time for performing this operation is when the bloom is just filled in, and the flowers are on the decline; but in that case the new plants are not so well rooted as those layered earlier, and consequently less able to stand the winter. Laying, by the wounds it inflicts, considerably impairs the bloom, and generally kills the parent plant. The practical part of the operation has nothing extraordinary in it; a sufficient quantity of pegs (fig. G12 a) and of compost being provided, the latter lower leaves (b) of the earth is then stirred, and the pot filled up with "light rich mould, not of too fine a grain." (Maddock.) The incision is made by entering a quarter of an inch below the joint, and passing the knife up through the centre of it; it is then to be pegged down, and buried not more than three inches deep. It is said by Maddock says, "to peg down the layers in a dry state, being then less brittle, and consequently not so liable to break off as when they are wet and succulent; therefore, as soon as the layers are dressed, the pot should be placed full in the sun for half an hour, in order to render them more pliable and plant them otherwise would be. When the layers are properly rooted, they are cut off from the old pot, or in about three weeks or a month after laying, provided due care be taken to keep them regularly moist, and to shade them from the heat of the meridian sun, they are then to be cut off from the old plant, with about half an inch of the stalk which connects them with it, and be immediately planted in three or four plants in each, placed round the sides. The pots are to be placed under a table, or an arch of hoops, where they can be covered with mats, in case of excessive rains, till the severity of the weather renders it necessary to remove them into their winter repository, which is in constructed in the same manner, and have the same aspect, as that described for auriculas." (Gardener's Dictionary, 1853.)

6411. Hogg commences laying when the flowers are sufficiently expanded to show which are in color, or true to their kinds, and which not: he finds it to be about the 21st of July, and he continues laying from that time to the 21st of August. The plants receive a good watering the day previous to laying, because there is often some one with the fine rose of the watering-pot, on account of preserving the earth on the laid shoots. In performing the operation, he cuts off the nib or extreme end of the tongue, or talus, immediately below the joint, because, "if left on, it is apt to decay," and prevent the protrusion of the fibres, which is the object of which the fibres proceed. Under favorable circumstances they will be fit to take off in seven or eight weeks, and may then be planted two or three in a small pot (No. 48), three inches in diameter, by four inches deep. The pots are to be set on tills, slates, or boards, there to remain (till the middle or end of October, when they are to be removed to their winter quarters. (Trellis, 50.)

6412. By piping. This mode of propagating the carnation is very precarious. Maddock says, "five thousand plants were piped one season, of which not more than one hundred perished; whereas more than two thousand were lost of the same number the year following, with but very little variation in the management. It is absolutely much safer by piping than laying, and makes healthier plants; it requires attention and experience to distinguish such sorts from the rest." Piping, however, is often a necessary resource where the shoots are too short for laying, or where in laying, shoots are broken by accident.

6413. The first thing is to provide a slight hot-bed, and cover it four or five inches thick with fine light mould, laid very regular and even. The cuttings intended to be piped are to have two complete joints, that is to say, they are to be cut off horizontally close under the second joint: the extremities or points of the leaves are likewise to be shortened, for laying, which will leave the whole length of the piping from one inch and a half to two inches, according to its strength (fig. 612 e): as soon as thus prepared, it may be thrown into a basin of soft water for a few minutes, to plump it up. The earth on the bed where the pipes are to be placed should be moderately moistened, and rendered rather compact than otherwise; then take a small hand-glass, and with it make an impression neatly on the surface of the soil, in order to know where to stick in the pipes, so as to lose no room, or even danger them being disturbed when the glass is placed over them. The pipes are then to be taken out of the basin singly, and forced into the earth, in their wet state, with a steady hand; but not more than half an inch deep. When a sufficient number for the glass are thus placed regularly, at equal distances from each other, and rather more than an inch within the mark described by the glass, on every side, they are to be gently watered, in order that the earth may adhere more closely to them, and thereby keep out the air; after this watering, they are to remain open, but not exposed to a hot sun, till their leaves become perfectly dry, after which the glass is to be placed over them carefully, on the same mark that was made by it upon the surface of the soil, before the pipes were placed there. The bottom edges of the glass are (to be forced a little into the earth, to prevent the admission of too much air, which so far finishes the operation. What further remains to be done is to attend diligently to their management, with respect to sun and air, &c.

6414. The soil ought to be kept regularly moist, till they have formed their fibres; but too much moisture is as prejudicial as too little, and whenever they are watered, the glasses are never to be replaced over them till their leaves
CARNATION.

6415. The glasses should be occasionally taken off to admit fresh air; if this material point is neglected, the consequence will be a green mossy appearance on the surface of the earth, and an universal mouldiness amongst the plants, while the glass will be covered with a deposit of paper and which, with the prudence of the cultivator; there is no great danger to be apprehended from taking off the glasses for a few minutes, or half an hour, when it is cloudy, and the air rather warm and moist; but if no opportunities of this kind occur in due time, it should not be done early in the morning, or very light air, lest the glasses off, if it is only for five minutes, turning them upside down on the path, in order to air them, and replacing them again over the plants; even this will be of great service, though not equal to a more effectual airing at favorable times, which, indeed, becomes more frequently necessary as the weather grows (still) warmer. The first objects to strike fibre, they will soon spindle up and become extremely weak, if not carefully attended to, viz. agreeably to the following directions: when their fibres are formed, which the additional verdue and growth of the plants will demonstrate, the glasses should be placed over them till the transition of the months, when the plants are in their full stature, and the glass root together; some are generally a few days or a week forwarder than the rest, as will be apparent by their superior growth and verdure: such ought to be carefully taken up and planted in small pots, for winter preservation, or they may be planted round the sides of large carnation-pots, filled with the compost, where they will soon make rapid progress; the remaining plants which are not sufficiently rooted for removal, must be continued under the glasses, as before directed, till they become.

6416. Care of pipings as to run or degenerated flowers. It is necessary to be very careful to mark such pipings as are taken off before it can be ascertained whether the original plant is in true colors, or run (or degenerated); because it very seldom happens that the pipings or layers, taken from a run flower, produce any other than run or plain-colored blossoms; in consequence they are not considered as so marked as that it may be accurately known from what plant or plants they were taken, in order that if any of the originals should prove foul in color, or run, the increase of such may be distinguished from the rest, and destroyed. The layers and pipings of the most beautifully variegated or ornamental flowers, and running plants, it is impossible to prevent its spreading amongst the rich high-colored sorts, when they grow in a rich compost. 

6417. Some people pipe their carnations at the third joint, but it is better to do it at the second; because, in the first instance, the third joint being more hard and woody, the pipings do not strike root, or form afterwards such as the nematode plants, as when they are piped at the second joint from the extremity of the shoot. (Flo. Direct. 202.)

6418. Hogg considers, that piping the carnation should commence sooner than laying, before the shoots get hard and woody; he begins it usually at the first of July. Plants raised from pipings, be considers as tender, and are very liable to endure the rigors of a sharp winter than layers; but still as laying is the surest mode, he only makes pipings of such shoots as appear crowded, or too short or too high up the stalk to be laid easily. He plants them on a bed of dung of blood warmth, in a compost of one third horse-dung, one sixth horse-dung, and one six of common dung, and when the glass is filled, that "the cuttings, when struck in, many enter easily and without injury. The piping should be cut with a sharp pen or budding-knife, at the second or third joint, according to the condition of the shoot; but the shorter the better. The cut must take place horizontally, close to the joint, and if the cover is not very thick external, be done. If the pipings are cut, the surface of the bed made flat and level, and gently watered through a fine rose, they may be stuck in three quarters of an inch deep, in rows not too near together. Then let them be watered again, which will help to fix the earth close round them; the glasses on no account to be shut down close till they are dry, or they will inevitably rot, fog, and perish. The best glasses for piping are those made of the common window-glass, eight inches square and six inches deep, and the less air they contain the sooner will the cuttings strike root. The striking-glasses in common use, which are blown for the purpose, though never filled up with so much glass, are useless. They require shading only when the sun is out, and then with a net or old mat, to admit the glimmering of his rays. If the weather continues dry and hot, they will require to be watered occasionally with a fine rose, early in a morning, over the glasses, which, for some time next after it, they are done in the day, if they keep them very dry; the sooner, for some occasion, for half an hour or so in a morning, to give fresh air, and dry the glasses; and if any of the pipings appear mildewed or rotten, pull them up. At the end of six weeks they will be sufficiently rooted to be transplanted into small pots or a prepared bed, but it would be better to plant them in a bed, till they were well rooted. There they may be allowed to remain till the middle or so of September. In taking them up, if you find any not rooted, but sound, and their ends hard and callow, do not let them remain upon the same spot, but remove them to another bed, with a little temporary, and cover them with glasses as before; this will not fail to start them and hasten their flowering." (Treatise, Sc. 22.)

6419. By seed. Carnation-seed is rather difficult to raise or ripen in this country, owing to the moisture and cold of the autumnal months. It is generally procured from Vienna and different towns, by means of thegvelling, keeping for years in the country. Maddock gives the following directions: "Those flowers which have but few petals, or, as it is more commonly expressed, are thin of leaf, generally produce most seed, and therefore are most to be depended on for a supply; but they should be possessed of the best proportion, in height and breadth, and many of the best sorts. If the plant be well taken care of, and their colors rich and regularly distributed, and in due proportion, throughout the whole blossom. The plants should be selected from the rest, and their pots should stand upon a stage, defended against earwigs, in an open part of the garden, in which situation they should remain, and until the seed is perfectly matured; their blossoms should be defended from rain, by having glass, paper, or tin covers (fig. 612. d), suspended over them, in such a manner as to admit a free circulation of air; the pots should neither be kept very wet nor very dry; nor will it be proper to cut and mutilate the plants, either for their layers or pipings. The seed, when ripe, will very generally contain, if not destroy, their seed. When the bloom is over, and the petals become withered and dry, they should be carefully drawn out of the pod or calyx, being apt to retain a degree of moisture at their base, endangering a mouldiness and decay in that part which will destroy the seed. The bloom-controlling succeeds successively introduced under the calyx, until the bloom is over, and the petals begin to decay, they are to be extracted as above, taking particular care to leave the two styles, which appear like horns proceeding from the summit of the germ, or future pericarp. 

The calyx (fig. 610. e) is then to be shortened to about two and a half inches in length, and may be used as a base of the pericarpium, so that no water can possibly lodge there; but in doing this, great care is necessary not to wound or injure the pericarpium, or seed-vessel, itself, because it might prove destructive to the seed. After the above is performed, the covers may remain or be taken away at pleasure; but in the latter case it is advisable to loosen the upper part of the stems from the stalks, that the open end of the calyx may incline a little downwards, the more effectually to
PRACTICE the nor the high to together lightens order carnations pens, about e. 6426. the day in the sides compost, its in all the compost may be added to it, either dissolved in water or strewed over with the hands. This, from an experience of three years, I have found to be attended with the most beneficial effect upon the future health and vigor of the plants. The compost covers the earth and protects the young seedlings from frost and wind damage, preventing the nutritious particles from being washed out. This is also an excellent precaution. If any objection be started that the quantity of dung is too great in proportion to that of the compost, I answer, that the compost were to be used immediately on its being mixed together; but as it has to lie six months, it is used, I am satisfied, not more than is necessary in order to a luxuriant growth and a generous bloom. For flowers that are apt to sport in color, such as Humphrey's Duke of Clarence, Plummer's Lord Manners, &c. he recommends the use of a sound staple compost of three parts of horse-dung, one half ditto horse-dung, a half ditto sand, a half ditto lime rubbish, or old plaster; to be prepared, and well incorporated, as before. He also uses the same compost for yellow picotees. (Treatise, &c. 45.)

423. Hogg says, "One article with respect to the soil for carnations you must certainly observe; never to use it when the earth has been kept dry; they, from certain experience, being a sure poison to the carnation, and vice versa." (Brit. Gard. 427.)

424. Manure of growing. The common sorts are planted in beds or borders, but the select kinds always in pots.

425. Pots and potting. Maddock uses pots for flowering plants, "at least twelve inches wide at the top, six inches at the bottom, and ten inches deep in the inside, with a circular aperture in the centre of the bottom, of about an inch in diameter; also three or four smaller holes round the sides of the pot, close to the bottom, to prevent the possibility of water lodging in remaining in that part." Hogg uses pots of twelve or sixteen to the cast, being smaller than those recommended by Maddock.

426. The operation of potting, according to Maddock, "should commence about the middle of March, if the weather is not extremely unfavorable; but it should not, on any account, be deferred later than the end of that month. The pot is first placed in the shell, with its hollow side downwards, placed over the hole in the centre of the bottom: this compost is to be higher at the sides of the pot, and the plants intended for it, which are supposed to be all necessary parts of the plant, contained in four pots, each of which is to be carefully turned out of their pots, with all the earth adhering to them; and after having been cleaned of all remaining pieces of the old mould, round about the plants, above their fibres, cleaning them and cutting off the decayed points of their leaves, the ball is to be carefully placed in the centre of the pot, and the space between it and the wall lined with the prepared compost. It is very necessary to be attentive in placing the plants, that they be neither placed deeper nor shallower than they were in the compost shopper. First, it is high enough to replace the old earth that was rubbed off on potting, exactly to the same height as before, i.e. half an inch higher than the ball of old earth and fibres; and the whole surface of the earth in the pot, when the operation is first performed on a young plant, will be nearly even with the surface of the compost than at the sides, because the plants would thereby be kept too dry; nor should the compost come nearer than within an inch of the top or rim of the pot, after it has been gently shaken, or struck against the ground, to be sure it has sunk in completely; we will admit its being too full, when the operation of laying comes to be performed, which requires some time after it has been laid on; and the two last pots are to be filled with the prepared compost. Hogg considers the first week in April as the safest and best time to pot carnations, and he performs the operation in the same manner as Maddock.

427. Culture. When the plants are potted off for potting, the pots should be placed in an open airy part of the garden, under a arch of hoops, that in case of cold drying winds, heavy rains, or frosty nights, mats may be thrown over, to preserve them from the effects of such unfavorable weather: in the hot weather, if they are to remain, always open to the air, except in the cases above mentioned, and be kept regularly watered with soft water from a fine-rose watering-pot.
When their flower-stems are grown eight or ten inches high, it will be necessary to support them with sticks, forced into the earth in the centre of the pot, to which the stems are to be loosely tied with small pieces of bass mat; these sticks should be as high as the hoops will admit, in order that the pots may remain under them as long as possible; but when the top hoop is reached, and there is not time for the blossoms to open, the small sticks should be replaced with others more suitable for the occasion; these should be about four feet or four feet six inches long, regularly tapering a little from the bottom to the top, and painted green; they should be substantial and strong enough to be forced into the earth deep and firm, not to be shaken loose by the wind. As the stems continue to advance in height, the tying, as above, must be also continued at about every five or six inches: it is proper to look over and examine the plants for this purpose every three or four days, as the stems are rather brittle, and liable to break, if they are not then in firm soil.

If any small, green, winged insects appear on the stems or foliage of the plants, particularly upon or underneath the flower-pods, they must be effectually exterminated or destroyed, either by the means of a small soft brush or feather, or by means of a dusting with a mixture of a strong decoction of a small portion of the scent of sassafras, and a sufficient quantity of the powder of coudio snuff, lighted, and blown through a small hole, in a small snuff-dust pipe, by the fingers. If this be done frequently, they will be easily avoided, by fastening a small narrow slip of bladder round the middle of the pod, where it is most swelled, and appears to have the greatest inclination to burst. The slip of bladder should be rather longer than is required to go once round, so that one end of it may lay over the other upon a little above the petal or blossom. Be sure to above a little stalk, which is quite necessary. The dust will adhere firmly together, and answer the purpose completely. Small slips of wet bass mat may be substituted for those of bladder, and being tied with a single knot round the same part of the pod, will answer nearly as well. (fig. G12, b.)

If any of the day's wine be allowed to remain in the pot, it must be drunk up by the flower-pods, or else it will injure them. Any fruit juice should be used as a stimulant for the blossoms, opening, and will, if neglected, soon manifest the effects of such neglect, by letting out the petals on one side, and thereby producing a loose irregular appearance, totally destroying that compact, graceful, circular form which a perfect flower ought to possess, and which is one of its principal ornaments. The flowers on the previous day's leaves (if any) will be damaged or spoilt, and, being taken down, answer in every respect for carnations: nor can any other more suitable be contrived or adopted.

In order that the flowers may appear to the greatest advantage, it is necessary that the pots should stand upon a stage or platform of boards raised about twelve or fifteen inches above the floor or ground; this stage should be very strongly supported, either by two or four pillars, of a size sufficient to prevent the immense weight of the pots, without danger of giving way; the supports of this platform should stand in shallow leaden or earthen vessels, filled with water, to prevent the access of earwigs, which are destructive enemies to the blossoms of carnations: they secrete themselves concealed in long night and morning, are driven out by light, or by any noise, and will probably be found sculking somewhere about the same pot, but not farther distant than the next, or next but one, unless the search has been deferred too long.

The flowers should be suspended from the sticks by small pieces of fine elastic brass wire (fig. G12, c), or they will be blown down, (as in the pin-shops,) to support them in an easy graceful manner, neither too near together nor remote from each other: one end of the wire should be introduced into the stick by means of a small awl, and there be fixed sufficiently tight to prevent its dropping out by the weight of the flowers and buds; the other end of the wire should be formed into a small ring, about a quarter of an inch in diameter, to enclose the stem between the calyx; this ring should be a little open on one side to admit the stem freely, without bruising it, which would materially injure the bloom.

Those who are particularly curious and fond of ensuring their flowers for preserving may carefully extract such petals as are likely to run from their true colours: they perform this by means of an instrument adapted to the purpose (fig. G12, F), and with the same arrange the remaining petals, so as to supply the defect; in like manner they dispose the whole with such regularity that the flowers appear to have an equal distribution of beautiful petals, imitations on every possible line of beauty, so that no part of the bloom is neglected, and if the blossom consists of too great a number of petals, they extract the smallest, and thereby afford the others more room to expand, which takes off the confused effect always produced by redundancy. The pots must be kept regularly and constantly watered, so long as blossoms are required; but when the ends of the petals are piped, and the flowers have attained sufficient size and beauty to ensure the full advantage of exposure to light and air, by drawing up the cloth covering, in the manner before described; but no rain must be admitted to the blossoms at any period of the bloom. Some place their stage, or platform, on one side, others in the centre of the room, and the whole row of pots on each side, with a commodious path in the midst, which is convenient and desirable. If the pots contain only two plants each, they consequently are not required to be so large as for four or five; but the latter have much the best appearance in bloom, producing a greater number of blossoms: it is not however advisable to permit every pod to blow, especially of late in the season, as it would weaken the plant and make it grow more slender than it otherwise would; if only one or two were left on each plant: it is, therefore, proper in this case to cut off, or draw out the smaller lateral pods, close to the main stem, as soon as they can be ascertained, in order that the remainder may have time to re-appear beneficially. In the following method of blooming, those sorts that are most slow in opening, must be permitted to blow, or else they will not come round to the same period; those sorts therefore, must be carefully observed, so as to keep the buds coming on evenly; and not to leave any to be too much produced, which would injure the bloom of the rest. Some few exceptions, but the instances seldom occur.

Carnations are to be treated, during winter, much like Auriculas: with respect to the weather, they are seldom injured by a moderate dry frost, though it is safer to defend them from too much of it; but it is very necessary to caution against covering them up close when the plants are wet, as they are, in
that state, very liable to contract a destructive mildew, if they have not the benefit of a free circulation of air; this mildew makes its first appearance in purple spots on the foliage, which can only be cured or prevented from spreading among the adjacent plants, by cutting out the infected part, or removing the pot, as soon as discovered, it being not improbable but that the distemper is, in great measure, owing to a very injurious, or rather the injurious warmth by the time the plants have been firmly established, because evaporation of air at all times, even when shut up, unless when closely covered with mats, &c. as in cases of severe frost; but at such times no such consequences are to be dreaded.

643. "The light and open air and generally more sufficient for carnations, as well as for auriculas, from an excess of which it is proper to defend them: of the two extremes, it is safer to keep them rather too dry than too wet at these seasons, especially during winter; but a moderate degree of moisture is always to be preferred, except when the weather is severely frosty. As too long a deprivation of moisture may appear injurious, whereby the plants are apt to shrivel, therefore, whenever the pots are closely covered with mats, for several days and nights, with little intermission, no opportunity should be lost during the middle of the day, if the sun shines, to take off the mats in front of the glasses, in order to admit its light and warmth. Whenever the surface of the earth in the pots becomes green with mould and adheives, it is proper to stir it up carefully, about half an inch deep, and to sprinkle a little coarse dry sand regularly upon it: this will prevent any great degree of tenacity in future, and be of great service; it may be repeated as often as required." 643.

645. In spring, the pots will probably require to be frequently watered, and by the middle of March the operation of potting is to commence, as already described. The blossoms of carnations, particularly the high-colored sorts, are very apt to run from their striped or variegated colors to a plain one; they are then esteemed of little or no value: but when they have only partially run, they may sometimes be recovered to their former state, by being planted in a poor dry soil, that will but just afford sufficient nourishment for their existence. (Florist's Direct. 166.)

645. "Hogg having potted his blooming plants, supports them with green sticks, in the manner of Maddock, and top-dresses about the middle of June with about half an inch of rotten horse-dung passed through a sieve. He finds many of the plants are apt to be injured, which prevents the preservation of the collection. Many," he says, "top-dress with some of the hotter manures of night-soil, sugar-baker's scum, &c. but, in my opinion, that is not necessary for carnations, and a paper bag, for, if the plants be not reduced to a proper size, they are apt to run entirely to the plants. He waters freely while the pots are swelling, and during the whole time they continue in blossom. As soon as the side shoots appear, he places "a paper collar round the bottom of the blossom to support it. These collars are made of white card-paper, in the form of a circle of three or four inches in diameter, with a hole in the centre just large enough to admit the calyx or pod, without much compressing, and with a cut extending from the centre to the outside or circumference, like the radius of a circle. On these cards the flower is preserved in shape and form a long time; on these the petals are also finely disposed, and the beauty of the carnation displayed to great advantage. We must confess, we think these collars a great deformity, and much prefer a tie of thread or bass mat, or the slip of bladder recommended by Maddock. When placed on the stage, they should have the benefit of the morning sun till about nine or ten o'clock, according to the intense heat of its rays; the same in the evening, with as much interval as will suffice the flower, when you can see it. In this place, Mr. Hogg preserves them in frames, in the same manner as he recommends for auriculas. When he has more plants than he can blow in pots, he plants them in beds of the same compost used for the others, protecting them from severe frosts and heavy rains, and in other respects treating them in the same manner as if in pots. (Treatise, &c.)"

646. "The pink is considered by many to be a subspecies of the D. caryophyllus, and by others to have proceeded from D. deltoidei, a British species, and the pleasant-eye pinks from D. plumarius. This flower, Professor Martyn observes, does not seem to have attracted any notice among our ancestors; and it is only within the latter half of the 18th century that pinks were much improved and varied, so as to be greatly valued among florists. It is now much cultivated everywhere, and especially in the manufacturing districts; in the neighborhood of Paisley, it is carried to a high degree of perfection. (See Part IV. Book I. Ch. III. Sec. 3.) The pink is much harder than the carnation, and less liable to the casualties incident to the latter."

647. Various. Parkinson, in 1629, mentions six or eight sorts. Rea, in 1704, says, there are many sorts, but of little esteem. Hogg, in 1830, gives a list of nearly one hundred names, as containing the best sorts in England; but Davy, who has raised more fine varieties of this flower than any one else, has above dole several new sorts, and the Paduan sort is reckoned above three hundred sorts."

648. "Carnation. As already stated, any pots or seed of carnations are apt to run too much to the pods, even when sown in a very fine and open soil, the seeds are tiny: the flowers, which are of the same structure as the pink, are more than half in diameter. The petals should be large, broad, and substantial, and have very fine fringed or serrated edges, free from large, coarse, deep notches or indentures; in short, they approach nearest to perfection when the fringe on the edge is so fine as scarcely to be discernible; but it would be considered a very desirable quality if they were perfectly smooth, and would be left at all. The broadest part of the lamina, or broad end of the petals (fig. 611. c), should be perfectly white and distinct from the eye, unless it be a faced pink, that is, ornamented by a continuation of the color of the eye round it (fig. 611. b), bold, clean, and distinct, leaving a considerable proportion of white in the centre, perfectly free from any tinge or color of the same. The color of the edges is a natural purple, or dark pink, of which, nearer it approaches to black, the more it is esteemed; its proportion should be about equal to that of the white, that it may neither appear too large nor too small." (Maddock.)

649. The same. Generally by pippings for ordinary purposes, sometimes by layers to preserve rare sorts, and by seed for new varieties.

650. By pippings. The time to commence this operation is generally previous to or during the bloom, or indeed as soon as the new growths are grown of a sufficient length for that purpose. Hogg recommends, first of all, to examine the operation of the knitting, should that be the case; if not, you may not apply bottom heat. This, however, is the more certain mode, and the pippings are ready to remove sooner, and generally in a fortnight or three weeks.

651. By seed. Proceed as directed for carnations.

652. Nicol has found great advantage from impregnating double and semi-double pinks, with single kinds, both in respect to fecundating more stamens, and producing in consequence more seed; but also in increasing the varieties, or new sorts raised from such seed. (Caled. Soc. Meni. iii. 270.)

**The double rocket is a biennial or imperfect perennial; a native of Italy, and cultivated by Gerrard in 1597.**

**The varieties are the white and purple, both very double, and forming a spike of about a foot long, of great beauty and fragrancy, and considerable duration.**

**Propagation and culture.** The plant is extremely difficult to preserve, especially near large towns. It does not thrive either near London or Paris; and both capitals, especially the latter, are supplied with it from provincial growers. It is very much grown in the west of Scotland, and in the Netherlands; and between Calais and Abberville it may be seen in great perfection in most gardens, especially if it proper soil, but flowers best in one of a lighter texture, like the boldi Cardinals. The best directions which we have met with for its culture are given by Robertson. (Caled. Mem. ii. 245.) He says, "The double rocket is a beautiful plant, rather scarce in this part of the country, owing chiefly, I imagine, to its being equally at home in London, Paris, and St. James." However, the number of plants of rocket under my care, and I did them all justice, as I thought, but all would not do; I lost them all. I tried to plant their roots, but being small and weak, the slugs eat them all up in a short time; as slugs are very fond of them, especially of their leaves. I tried to increase them by cuttings in the common way, with as little success. This led me to try another

---

**Book II. DOUBLE ROCKET.**

6447. Mode of growing. The common sorts are introduced in borders, and the better varieties in prepared beds. Sometimes rare sorts are planted in pots, but in general they thrive better in the open garden. **6448. Soil.** Madowick says, "A good fresh loamy soil, dug and comminuted about two feet deep, and manured with a stratum of cow-dung, where the beds are situated, will be found to be the best.** This soil should be about six inches thick, and kept free from weeds, and covered with straw or ashes. **6449. General culture.** As soon as the pipings are two years strong, they are to be planted on a bed of common garden-mould, where they are to be left for ever. The ground is to be turned over the flowering-bed in March. **This bed should be raised three or four inches above the surrounding paths, and its sides may be supported with an edging of boards, to come up even with, or one inch higher than its surface; this last, more for the sake of neatness than any particular utility it will be of.**

6500. The plants intended for the principal bed for bloom, should be placed upon it in August, or early in September, as they do not blow quite so well if removed later in the season; they should be planted at about the distance of nine inches from each other, and the bed should be laid to a rather lower convex than the other, so as not to allow any other cropping than a very slight one in case of severe frost. The bed should be kept free from weeds, and its surface stirred up a little if it inclines to bind, or, in other words, whenever it becomes too firm and adhesive. Larger strong plants will put up numerous flowers, and a mot it or this stems before blooming; a more robust plant, the largest and strongest should be left, especially the leading stem, which proceeds from the heart or centre of the plant, together with all its best pods; but no plant, however strong, should be permitted to bloom more than ten or twelve blossoms, nor weakly plants more than four or five. In order to obtain them large and well, it is of the utmost importance that no cut or pruning of sorts should be made, as they never produce any other than diminutive flowers, and at the same time rob the others of a certain part of their nourishment, which, of course, prevents their attaining the size and beauty they would otherwise arrive at.

6501. The lead and most ruffly plants do not produce the finest flowers; they naturally put forth numerous small stems, which their roots are not able to support sufficiently to produce large blossoms. Strong healthy plants, not too large, and consisting of a capital leading stem in the centre, with but little surrounding increase, are most proper to select for the best bed; these will seldom put up more than one or two heads, which will, however, be very strong, grow tall, and produce three or four blossoms, as large and fine as the sort is capable of.

6502. Those pods that appear in danger of bursting should be tied in the same manner as directed for carnations under similar circumstances. Such sorts of pods as are most inclined to burst their pods, often will not produce large and beautiful flowers, nor those which have smaller pods, because the latter generally consist of too few petals; it is, however, more desirable to have their pods large and long, than too short and round, as it is hardly possible to preserve the latter from bursting, whereby the beautiful circular forms of the petals are destroyed. When the calyx before blooming burst, it is very difficult to prevent its evitably bursting, it is better to assist nature by what is called letting down the pod, that is, with a pencil to nick it down at the bottom of each of its indentures, as low as may be deemed necessary, in order to let out the petals regularly on every side, and preserve the circular form of the petals; for when it is left untouched, the calyx will burst only on one side, and its petals will consequently force their way through that aperture, and produce a loose deformed flower; some kinds are possessed of such weak and short pods, that the calyx (fig. 51.) will entirely burst from top to bottom on one side, and open so very wide as to suffer almost all the blossoms to be lost. This has been a great harm to have been in bloom but a short time; such indeed hardly deserve to be classed amongst the best sorts, let their properties, in other respects, be ever so desirable. When the flower-stems are grown sufficiently long, they should be supported with small sticks or wires, or the fancy of the cultivator may direct; but these ought to be disposed of in such a manner as to allow the blossoms to expand and blow perfectly distinct from each other, that the whole may have an easy graceful appearance. Those who can bestow sufficient time and attention to their bloom of picks, may contribute greatly to the effect, by placing upon the calyx the thin pieces of card, or stiff paper, cut circular (fig. 61.) already mentioned (6438); these are to be placed close underneath the guard-leaves, so as to support them horizontally, and will, when the flower comes on, prevent the blooming-bed from being crowded.
method, which I would recommend as a never-failing way of propagating this beautiful flower. If a person has but one plant of rocket, and is anxious for its flowers, the first thing is, after the flower is beginning to fade, to eat down the stalks and divide them into ordinary lengths of cuttings; next to cut off the leaves, and smooth the ends; then to make three slits with a knife in the bark or rind, longways, so as to separate or raise the bark for half an inch in length. When the cutting is inserted in the ground, the loose bark naturally curls up; and it is from this bark that the young roots proceed. The partial separation, and the turning up of the bark, seems to promote a tendency to throw out roots. The cuttings may be put into flower-pots, as they may thus be sheltered during winter with more ease; or they may be placed in the natural earth, provided the soil is light and fresh. Covering them with a hand-glass will forward the rooting of the cuttings; or with the aid of the latter, they will succeed excellently. I have used this simple way for six years back, and never without success; not one in twenty having failed. This method, it may be remarked, will hold good in cuttings of stock-gillflowers, and double wallflowers."

6459. There are three species of lobelia which rank high as florists' flowers.

6460. The common cardinal flower (L. cardinalis) (Bot. Mag. 320, and fig. 613.) has roots composed of many white fleshy fibres, oblong leaves, stalks erect, about a foot and a half high, terminated by a spike of flowers, "of an exceedingly beautiful scarlet color," appearing in the end of July and August. It is a native of Virginia; and it is found abundantly by the side of rivers and ditches: introduced in 1629. Justice is in raptures with it, describing it as "a flower of most handsome appearance, which should not be wanting in curious gardens, as it excels all other flowers I ever knew in the richness of its color." There is a dwarf variety, but it is very liable to perish.

6461. Propagation and culture. By seeds, offsets, or cuttings; but the former method produces the strongest plants. Sow in pots of rich earth soon after the seed is ripe, and place them under the protection of a frame. The seeds will appear the following spring; and after they have two or three leaves, should be planted in separate small pots, and shifted into larger ones once or twice during the season. Place them in an eastern exposure, and supply them freely with water. Protect, during winter, by a frame; and the following spring, shift them into pots, six or eight inches diameter, in which they will flower. If not much exposed to the sun, they will continue long in beauty. The roots do not last above two or three years; and therefore a succession of young plants, from seed or slips, should be regularly provided. (Mitter.)

6462. The fulgent cardinal flower (L. fulgens, W. en.) (Bot. Rep. 659. and fig. 614.a) is a native of Mexico, and was introduced into England in 1809: flowers in July and August. Though a native of a warm climate, it has been found to bear the severity of our winters, by being immersed in water, as an aquatic, and with this treatment has flowered well by the sides of ponds and in cisterns.

6463. Propagation. By suckers or cuttings, which strike with remarkable facility in any shady situation; and by seed. According to Professor Van Mons, "the seed should be sown, as soon as it is ripe, in earthen pans; the earth should be moistened, and after it has imbibed the water, the seed must be spread over it without being covered. The pans should be sheltered from the frost, and the young plants may be transplanted in April and May. Very few of them remain, more than the second year, without flowering."

6464. Culture. This plant has assumed a character of uncommon magnificence under the management of Heigges, which is thus detailed by Sabine: "In October, he takes off the suckers, which are thrown up from the roots of the old plants, and puts them into small pots, one in each pot, and keeps them in a cold-frame till the middle of January: he then removes them into a cucumber-frame, where the heat is kept up to 65 degrees of Fahrenheit's scale, by linings of hot dung; a pine succession stove of the same temperature will equally suit them. In the middle of February, they are shifted into pots a size larger; and at the end of March, or beginning of April, they are again moved into larger pots, and in the middle of May they are a third time shifted; the pots to be used for this last shifting are twelves. As soon as the plants are well rooted, after last removal, they are carried into a peach-house or green-house, in which they continue till they flower, and are hardy enough to bear the open air. When they are preparing to throw up their flowering stems, and during their growth, it is necessary that they be kept very moist, which is effected by putting pans under the pots, and keeping the pans constantly filled with water. The plants thus managed, begin to flower early in July, and the spikes continue to blow, and are covered with flowers through the autumn. The compost used in the pots is formed of equal parts of brown or yellow loam, and of leaf or bog mould, to which is added sand, equal to one fourth of the previous composition, the whole being well mixed together. The plant of Lobelia
6465. The splendid cardinal flower (L. splendens, W. en.,) (Bot. Reg. 60. and fig. 614. 6), a native of Mexico, and introduced in 1814, may be treated like L. fulgens; and the blue cardinal flower (L. splillicita) (Jae. ic. iii. t. 597.), a native of Virginia, and introduced in 1665, may be treated like L. cardinals.

6466. The pyramidal bellflower, in its cultivated state, has thick ramose roots, which are milky; oblong leaves; and strong stalks, four feet high, from the sides of which the flowers are produced for more than half their length, forming a sort of pyramid. The most common color is blue, but there is a variety with white flowers. It is a native of Istria and Savoy, and was cultivated by Gerrard in 1596. Formerly it was in demand as an ornament to halls, and for placing before chimneys in summer, being planted in large pots, and trained in the fan manner, so as to cover a large surface. In the shade it continues in flower for two months or more.

6467. Propagation and culture. By seed, cuttings from the stem, or by dividing the roots; the last method makes the strongest plants in the shortest time. The season for this operation is after the bloom has faded in September; the sections are to be planted in pots, and protected by a frame during winter. In spring they may be transplanted into large pots, and in the beginning of summer into still larger ones, in which they are to flower the summer following.

6468. By seeds. The plants so raised, Miller says, are always stronger, and the stalks rise higher, and produce a greater number of flowers. Good seeds are to be obtained by placing a strong-flowering plant in a warm situation against a wall or under a glass case. They are to be sown in pots of light earth soon after being gathered, protected by a frame during winter, and will come up in spring. When the leaves decay in October, they are to be transplanted to beds of light sandy earth, without any mixture of dung, which is a great enemy to this plant. Here they are to remain two years, being protected in winter by rotten tan; they are then to be removed to their final destination in September or October, and the year following, being the third from sowing, they will flower. The plants, Miller observes, of this species, as of many others which have been long propagated by roots, offsets, or cuttings, do not so readily bear seed as those which have been raised from seed.

6469. The C. Carpathica, grandiflora, and several other very showy species, may be similarly treated.

6470. The Chinese chrysanthemum is a fibrous-rooted half-hardy perennial, with pinnate, gashed, serrated leaves, leafy stems, from three to four feet high, and flowers generally on solitary peduncles. It is a native of China, where it is highly prized and extensively cultivated as an ornamental plant, and was introduced in 1764. Here it contributes greatly to the beauty of the flower-garden in a fine autumn, and of our conservatories in November and December, when scarcely any other plants are in flower.

6471. Varieties. The Chinese are supposed from good authority to have fifty varieties or upwards: there are twenty-three sorts described by Sabine, as having flowered in this country, and there are a number more, of recent introduction, which have not yet flowered. Through the exertions of the Horticultural Society, and some nurserymen, and private individuals, it is expected all the Chinese sorts will soon be imported. Sabine describes as having flowered in the garden of the Horticultural Society, and as to be procured in the nursery, the following:

(Sabine, in Hort. Trans. vol. iv. p. 224. & vol. v, p. 149.)
6472. Propagation. By dividing the root, by suckers, and by cuttings: the latter is the best mode, as producing plants less likely to throw up suckers. The cuttings are usually taken from the side branches in August, planted in shallow pots, placed in a warm shaded spot, and covered with a hand-glass. In a month or six weeks, they will have struck, and are then put into pots of the smallest size, and put in a warm situation, where they remain till November; they are then placed under a frame for the winter.

6473. The soil used generally for the chrysanthemum, is two thirds of turfy or virgin loam, and one third of leaf-mould or decayed dung.

6474. Culture in pots. In April, the cuttings of the preceding autumn are shifted into No. 92 pots, and set out into a well sheltered south border, on a bed of scorzoe, for the summer. About the beginning of October, when the flower-buds are formed, they are taken into the green-house, on the stage of which they are exposed as much as possible to the air, both night and day, in good weather, but protected by the lights from wind, rain, and frost. The Chinese also propagate the chrysanthemum by cuttings; but they take them off in May, strike them as we do, and then put each plant in a small pot, in which it flowers the succeeding autumn. By this means the plants are much dwarfer than ours usually are, and instead of having great part of their stems naked, or covered with withered leaves, they are clothed with green foliage from the ground to the flower. In order that the blossoms may be strong, they pinch off all the flower-buds, excepting three, or five, or sometimes only one, as soon as they appear, and are liberal in the use of liquid manure; those which remain are as large and fine as are produced by the most bulky plants. (Wells, in Hort. Trans. vol. iv. 571.) This is by far the most simple, elegant, and economical mode of propagating this beautiful flower; it has been practised several years by the Comte de Vande, at Bayswater, as well as by others in this country, and whenever it is generally known will be as generally adopted. All suckers should be removed, only one or three stems trained erect, and branching regularly on all sides. The side branches and top, or head, should be so arranged and adjusted by a nice application of black threads and wires, attached to the main prop as to render the figure of the entire plant perfectly symmetrical. Three stems may be trained, though one is better than three, because it will grow stronger: but three are better than two, which do not compose a whole; and better than a greater number than three, because unity departed from, there is no limit to irregularity. One and three are unity; because one is complete, and three has a beginning, middle, and end. All possible numbers besides, either fall short of or exceed unity; they are irregularities, and irregularities are redundant and infinite, and therefore unsatisfactory to contemplate.

6475. Culture in the open border. Many of the sorts may be planted out in warm borders, or compartments, or against walls, and will flower well in fine autumns; but their roots require protection through the winter, and they should be renewed about every two years; for as they increase much in size by suckers from the roots, the plants, if left for a longer period, become unsightly, and produce small and imperfect flowers. The early flowering varieties, as the purple, changeable white, rose, and buff, seem the hardiest and most suitable for borders. (Sabine, in Hort. Trans. vol. iv. 323.) To look well in the border the plants should be large, and with many stems; their flowers are consequently more numerous, and produce a greater effect at a distance. The appearances of the flowers on many of the kinds is very different when blossoming in the borders from those which expand under glass, so much so, that they might be easily mistaken by an unexperienced observer for different varieties. (Hort. Trans. vol. v. 162.)

6476. The hydrangea is a very low under-shrub, producing broad green leaves, and cymes of monstrous flowers, like the guelder rose in form, and red in color, changing to white and green. Its native place is unknown; but it is commonly cultivated in the gardens of China and Japan, from whence it was introduced to Kew by Sir J. Banks in 1790. It is much valued as a chamber plant, and in consequence, extensively cultivated near London and most large towns of Europe.

6477. Varieties. Soon after it was introduced, some plants were found with blue flowers, which some supposed to be produced by salt or saltpetre, and others by oxide of iron. The yellow loam of Hampstead heath and some other places, and some sorts of peat-earth are found to produce this effect; but the cause is not yet ascertained. Dr. Daalen, of Antwerp, finds that turf-ashes, and still more effectually those of the Norway spruce, the wood generally used as fuel by him, applied to the roots of hydrangea, produced the blue color of the petals. (Hort. Tour, 122.) According to Busch, of Petersburgh, "the hydrangea will be turned blue by watering the young plant, the summer
BALSAM.

Pent.

all

if

6479. The balsam is a tender annual, rising from one to two feet high, with a succulent branchy stem, serrated leaves, and various-colored flowers. It is a native of the East Indies and Japan, where the natives, according to Thunberg, use the juice prepared with alum, for dying their nails red. Cultivated by Gerard in 1596.

6480. Varieties. These are infinite, but not so marked or permanent as to have acquired names. The seed from one plant will hardly produce two alike. Double flowers are chiefly held in esteem, and especially those that are striped like flaxes and bizarre carnations.

6481. Propagation and culture. It can only be raised from seed, which ripens readily from semi-double plants, and should not be less than three or four, or even nine years old, gardeners having experienced that new seed seldom produces double flowers. The best soil is a rich loam, rather lighter than that used for growing melons. At any period between the 1st of March and 1st of May, sow very thin in pots, to be placed in a warm frame. When large enough to handle, transplant into No. 48. pots, one plant in the centre of each pot. As soon as the roots have filled the pots, move them into pots a size larger, and repeat this operation three or four times, till at last they are in pots of eight inches' diameter, and all the flower-stalks, except the last, are removed. The balsams so grown will rise four feet high, and fifteen feet in circumference, with strong thick stems, furnished with side branches from bottom to top, and these covered with large double flowers. (Fairweather, in Hort. Trans. li. 406.)

6482. The Amaranthus, Celosia or cockscomb, Comphrena or globe-amaranth, Mesembryanthemum crystallinum or ice-plant, Solanum melongena or egg-plant, and most other tender annuals, will attain to corresponding luxuriance, if similarly treated.

6483. Knight, in October, 1820, sent to the Horticultural Society a cockscomb (Celosia cristata), the flower of which measured eighteen inches in width and seven inches in height, from the top of the stalk; it was thick and full, and of a most intense purplish-red. To produce this, the great object was to retard the protrusion of the flower-stalk, that it might become of great strength. The compost employed was of the most nutritive and stimulating kind, consisting of one part of unfermented horse-dung, fresh from the stable, and without litter, one part of burnt turf, one part of decayed leaves, and two parts of green turf, the latter being in lumps of about an inch in diameter, in order to keep the mass so hollow, that the water might have free liberty to escape, and the air to enter. The seeds were sown in spring rather late, and the plants put first into pots of four inches' diameter, and then transplanted to others a foot in dia-

3 K
PRACTICE OF GARDENING.

PART III.

6484. The mignonette is a trailing hardy annual, a native of Africa, and introduced in 1752. It is "the Egyptian bastard-rocket, with most sweet-smelling flowers," of Justice, and the Dutch florists of his day. The flowers are highly odoriferous, and the plant in pots is in universal request, at all seasons of the year, for placing in rooms.

6485. Varieties. There is a sub-biennial semi-frutescent variety, rather more odoriferous than the common sort, which forms an elegant winter plant for the drawingroom, but which is not yet in very general cultivation.

6486. Propagation and culture. Rishon, who cultivated this plant extensively for the London market, gives the following instructions, as applicable to the common variety: "To obtain fine plants, strong and ready to blow, during the winter, and through the months of January and February, the seed should be sown in the open ground the end of July; by the middle of September, the plants from this sowing will be strong enough to be removed into pots; for a week after this removal, they must be shaded, after which they may be freely exposed to the sun and air, care being taken to protect them by frames from damage by heavy rains, and from injury by early frosts, until the beginning of November, at which time many of them will show their flowers; and they should then be removed to a green-house or conservatory, or to a warm window in a dwelling-house, where they will branch out, and continue to blow until the spring. The crop for March, April, and May should be sown in small pots, not later than the 25th of August; the plants from this sowing will not suffer by exposure to rain, whilst they are young; they must, however, be protected from early frosts, like the winter crop; they are to be thinned in November, leaving not more than eight or ten plants in each pot; and at the same time, the pots being sunk about three or four inches in some old tan or coal-ashes, should be covered with a frame, which it is best to place fronting the west: for then the lights may be left open in the evening, to catch the sun whenever it sets clear. The third or spring crop should be sown in pots, not later than the 25th of February; these must be placed in a frame, on a gentle heat, and as the heat declines, the pots must be let down three or four inches into the dung-bed, which will keep the roots moist, and prevent their leaves turning brown, from the heat of the sun, in April and May. The plants thus obtained will be in perfection by the end of May, and be ready to succeed those raised by the autumnal sowing." (Hort. Trans. ii. 375.)

6487. The tree-mignonette, according to Sabine, "is to be propagated from seeds sown in spring; it may also be increased by cuttings, which will readily strike. The young plants should be put singly into small pots, and brought forward by heat, that of a gentle hot-bed being preferable, but they will grow well without artificial heat. As they advance, they must be tied to a stick; taking care to prevent the growth of the smaller side shoots, by pinching them off, but allowing the leaves of the main stem to remain on for a time to support and strengthen it. When they have attained the height of about ten inches, or more, according to the fancy of the cultivator, the shoots must be suffered to extend themselves from the top, but must be occasionally stopped at the ends, to force them to form a bushy head, which, by the autumn, will be eight or nine inches in diameter, and covered with bloom. Whilst the plants are attaining their proper size, they should be shifted progressively into larger pots, and may ultimately be left in those of about six inches in diameter at top." (Hort. Trans. iii. 181.)

SECT. II. Border-Flowers.

6488. Border-flowers are hardy plants, with showy blossoms, of easy culture, and their use in floriculture is to decorate the flower-garden, shrubbery, and other spots or borders considered as ornamental. We shall take them in the order of perennials, bulbs, biennials, hardy annuals, and half-hardy annuals; and arrange each of these subdivisions according to their time of flowering, heights, and colors: indicating by letters those requiring peat-soil (p); such as are rather tender (t); such as are most showy (s); and such as continue in flower for two or more months (s). At the end of each subdivision we shall give its general mode of propagation and culture. It may be added, that most of the plants mentioned as flowering in any particular month will often come into flower the month preceding, and continue in bloom during one or more of the following months. Hence the importance of selecting such flowers as are at once the most easy of cultivation, beautiful in appearance, and that continue longest in flower.
### PERENNIAL BORDER-FLOWERS. — FEBRUARY AND MARCH.

#### Subsect. 1. Species and Varieties of Perennial fibrous, ramose, tuberous, and creeping rooted Herbaceous Border-Flowers, arranged as to their Time of Flowering, Height, and Color.

#### Height from 0 ft to 2 ft. of fl. From 2 to 4 ft. of fl. From 4 to 6 ft. of fl. From 6 to 8 ft. of fl. From 8 ft. upwards.

6490. Propagation of perennial herbaceous plants. All the modes of propagation, excepting such as are applicable only to woody plants, may occasionally be adopted; but the most general practice is by dividing the root, by suckers or offsets, and by seed; the other modes are by cuttings of the stalks, shoots, or roots, and by layers.

6491. By dividing the root. This mode is applicable to nine tenths of hardy herbaceous plants. The plant may either be taken up, divided with the knife, and a portion replanted to continue the species in the spot allotted to it; or, the earth may be partially removed, and part of the roots and crown cut off to make new plants. The sections may, if well rooted, be planted at once where they are to remain and flower, or, what is preferable, they may be planted for one season in nursing-beds in the reserve-garden, and prevented from flowering that season by pinching off the flower-buds as they appear. The common season for performing the operation is spring, when the plant is beginning to push, or in summer or autumn immediately after it has flowered. The latter is generally the preferable period, unless the plant flowers very late, in which case the sections will not have sufficient time to form roots for their support during winter.

6492. By suckers or offsets. This mode is also applicable to nine tenths of common herbaceous plants; the best time for removing them is in spring, or early in summer, after the plant has begun to grow. Plant them in the nursing-department, and pinch off their flower-buds, that they may flower strongly next season when removed to their final destination.

6493. By seed. This mode is applicable to all the single-flowering kinds, but is only adopted with a few species, which are otherwise difficultly multiplied. Collect the seed from the flowers which expanded first, as being generally the strongest. If it is ripe before August, it may be sown the same season, but if otherwise, it will be preferable to defer sowing till the following spring. Sow on beds of light earth, thinly covering according to the size of the seed, and prick out the plants once or twice according to their strength, size, or weakness, so as they may be fit to remove to their final destination in August or September. They will flower strongly the following year, and probably may show some new varieties.

6494. By cuttings from the side-shoots or flower-stems. This mode is applicable to a number of the more delicate and double-flowering herbaceous plants, as to scarlet and pink lycis, double rockets white and yellow, some hollyhocks, and a variety of others; but more to biennials and annuals than to perennials. The cuttings may be taken off at any time when the shoots are tender and properly prepared, and planted in sandy loam in a warm situation, but shaded and covered with a hand-glass. Afterwards transplant them in the nursery-department, and again the same season where they are finally to remain. They will blow freely the summer following.

6495. By cuttings from the root-shoots. This is applicable to some sorts which do not multiply fast at the root, or whose rooted stolones or suckers do not make handsome plants; as to some species of alyssum, statice, silene, &c. The early part of summer is, in general, the most fitting season for performing the operation; plant in sandy loam under a hand-glass, and shade in the sunny part of the day; then transplant in the nursery department for a few weeks, when the strongest plants will show themselves, and may be removed in September to their final destination. They will blow strongly next year.

6496. By cuttings of jointed root-shoots or pippings. This is chiefly applicable to the dianthus tribe, saponaria, the striped grass, or any other grasses or reedy plants. Proceed as in piping pinks or carnations (6412.); but no bottom heat will be required for the sorts that come under this section.

6497. By cuttings from the roots. This is strictly applicable only to such plants as form buds on their roots, as to most of the rubiacæ, to the mints, epilobiums, &c. About midsummer is the earliest period at which the creeping roots are generally fit for this purpose; but with some others, as gallium, osmundæ, &c. it may be done in spring.
Plant the cuttings in the shade, and afterwards transplant and treat them like cuttings from the flower-stalks or root-shoots.

6498. *By layers.* Such plants as cannot easily be propagated by any of the foregoing modes may be increased by layers; such as the carnation, some species of salvia, sibbaldia, sibthorpiav, some silenes, &c. Commence the operation when the plant begins to flower, and when the layers are rooted, treat them as directed for pipings.

6499. *General culture of fibrous-rooted herbaceous flowers.* Autumn, after the plant has done flowering, or spring, when it has begun to grow, as has been already observed (6189.), are the seasons for planting or transplanting. The general culture is, stirring the soil; renewing it according to the kind of plant (6188.); taking up overgrown plants, reducing them, and replanting (6190.); sticking, pruning, trimming, removing all useless, decayed, injured, or diseased parts; and supplying blanks. (6192.) The general management consists in attending to order and neatness. (6201.)

6501. Propagation of bulbous-rooted flowers. By offsets or by seed; the whole, with the exception of the cyclamen, and one or two others, are propagated by offsets, which are to be taken off when the plant is in a state of rest, which happens in most sorts after it has done flowering; afterwards they are to be planted in a nursery-bed for one year, and where they are finally to remain the year following. Autumnal-flowering bulbs are not in a state of rest till the beginning of the following summer: as the colchicum, autumn-flowering crocuses, amaryllis lutes, and a few others. These, therefore, are to be taken up when their leaves begin to decay early in summer, their offsets separated and planted in the nursery-department, and the parent bulbs replaced in a month or six weeks, in order that they may have time to establish themselves and flower before winter.

6502. General culture and management. Bulbous-rooted flowers differ from others in requiring in their cultivated state to be frequently taken up and replanted. Fibrous-rooted plants which grow much at the root, require this occasionally; but almost all bulbs frequently. The reasons are, that in deeply comminuted rich ground, most sorts, but especially those which form their new bulbs beside the others, multiply so fast that the bulbs become crowded, small, and unfit to send up strong flowers; that many sorts, as in narcissus, tulip, &c. which form their new bulbs under the old one, send down their bulbs at last so deep that they at first come up weakly, and afterwards cease to appear at all, as in the bulbous-rooted irises, colchicum, &c.; and that some, on the contrary, which form their new bulbs over the old ones, send them up at last above the surface, as in crocus, gladialis, &c.; and are consequently killed by the frost or drought. Hence the finer bulbs of florists require to be taken up every year, and all the border-bulbs at least every three or four years. The time to do this is when the plant has flowered and the leaves have begun to decay. No bulb should be taken up for any purpose, or injured in its growth in any way while the leaves are green; for it should ever be remembered by gardeners, that it is the leaves which bring the root to maturity and prepare it for flowering the following year. If these are injured or cut off, or if the plant is transplanted, unless with such a ball as not to touch any of its fibres while in a growing state, the bulb will not recover so as to be able to flower for at least one year, and probably two or three. The time for keeping bulbs out of ground depends on their habits as to flowering. The object is to heal the wounds made by removing the offsets, and perhaps by setting the bulb more completely in a state of rest, to render it more excitable when planted. A month will in general be sufficient for this purpose, and more cannot be allowed with safety to the autumnal-flowering bulbs: more than three months is more likely to be injurious than useful to most sorts, though hyacinths, and other bulbs which form articles of general commerce, are frequently kept out of the soil half the year: when planted so late, however, they seldom flower well the first season, and commonly not at all for a year or two afterwards. The taking up, drying, and replanting of border-bulbs must be attended to by the flower-gardener with equal regularity, though not with equal frequency as the finer, select, or florists' bulbs: the offsets may be planted in beds in the reserve-garden, if wanted for stock; and the soil of the spot where the plants stood in the border renewed according to its kind, and the flowering-bulbs replaced. Some bulbs multiply so fast by throwing out offsets, that they soon cease to send up flower-stems: Of these may be mentioned the ornithogalum umbellatum, luteum, and some other species; some species of scilla, muscari, iris, allium, oxalis, and others. These should either be annually taken up, their offsets removed, and the parent bulb replanted; or the offsets, as soon as they send up leaves, should be destroyed. Indeed, whenever strong-blowing bulbs is the principal object, the offsets should never be allowed to attain any size; but as soon as they indicate their existence by showing leaves above ground, they should be removed with a blunt stick, or in any way least injurious to the parent. By this practice a great accession of strength is given to the main plant, both for the display of blossom during the current season, and for invigorating the leaves to prepare and deposit nutriment in the bulb for the next year. In pursuance of the same objects, every flower should be pinched off as soon as it begins to decay, but the flower-stalk may remain till it begins to change color with the leaves. Some bulbs are greedily sought after by vermin: as the crocus and tulip by the mouse and water-rat; the snowdrop and some of the narcissi by the snail and slug; and the hyacinth by a particular sort of grub-worm. We know of no method of mitigating these evils but by catching the mice and rats, gathering the snails, and taking up, drying, and replanting in fresh soil, the roots attacked by worms or insects. The snail is perhaps the worst of these vermin, and, fortunately, it may be most effectually kept under, by scattering leaves of the brassica tribe (of any variety) over the ground, and picking from them, every morning, the snails which have fixed on them during the night.

6503. Most bulbs force well; to expedite this, retard the bulbs by keeping them in an ice-house till the autumn of the second summer; put them in water-glasses or pots in September, and they will be in full blow by Christmas.

6505. *Propagation and culture of biennial border-flowers.* They are all raised from seed, but some of the finest double varieties are continued by cuttings. The seed of such sorts as ripen by August may be sown immediately after it is gathered; but the seed of those sorts which ripen later should be preserved till the following spring, and sown in May or the beginning of June. Sow thinly in beds in the reserve-garden, transplant into other beds when the plants are a few inches high, and in September or October remove the plants to their final destination. If this be, as it most generally will in the mingled flower-border, to provide a succession of the same sorts, then it can only be done in the case of those sorts which are done flowering by September or the first of October, and the others must be removed early in March with hocks. Great care is requisite in removing some sorts which have large tap-roots, as *œnothera*, hollyhock, lavender, &c., for if materially checked they will not flower strongly. The best mode is to nurse these sorts in large pots, and transplant them in October or February, with their hocks entire. The sorts continued by cuttings are chiefly fine double varieties of wallflowers, stocks, rose-campions, &c. The cuttings may be taken from the flower-stalks, or the root-shoots, early in summer, put under hand-glasses, and otherwise treated as cuttings of perennials. If the cuttings of some sorts, as *dahlia*, chrysanthemum, lobelia, &c. are taken off early in the season, they will flower in the autumn. The plants once placed where they are to remain, their general culture and management is the same as for the perennial border-flowers. (6187.)

**6597. Propagation and culture of hardy annual flowers.** They are all raised from seed, though occasionally some fine varieties of cheiranthus, viola, &c. are preserved by cuttings. The seed is generally sown in March or April, in patches or rings in the borders where the plants are to flower. The ground is previously stirred and made fine; the patch is sown of a circular form of six or eight inches' diameter, or a row only is sown in the circumference of the circle, the seeds covered according to their size, and the plants, when they are an inch high, thinned out to one, three, five, seven, or more, according to their kind. This, and occasionally stirring the soil, with staking, &c. as in perennial flowers, is all the culture they require. Sometimes the whole, or many of the sorts, are sown in the reserve-garden, and transplanted where they are finally to remain. This answers well for such sorts as the lupin, sunflower, and sweetpea; but is rather precarious with such early flowering and short-lived sorts as annual stocks, candytuft, Venus's looking-glass, &c.
6508. Seed may be saved either from the top and first-expanded blossoms of plants in the borders, or from patches shown in the reserve-garden. For the sake of neatness and beauty, no more flowers on each plant ought to be allowed to ripen their seeds than are wanted for the supply; but unless for varieties difficult to procure from the seedsmen, the simplest, and indeed the most economical mode, is to procure supplies yearly from them.

6509. Some very pleasing conceits for arranging annual flowers are given by Swindon (Beauties of Flora, 1778), a Brentford nurserian. He gives a copious list of annuals, arranged according to their heights and colors; and by affixing a number to each sort, he can readily inform his plans the kinds to be employed, and their relative position. Thus he has 59 sorts of common hardy annuals, arranged in six different classes, for six different ranges, in borders, as follow:—

First range, which grow from 8 to 12 or 14 inches high.
1. Cape marigold; purple and white.
2. Centaury; red, yellow, and red and yellow.
3. Venus's looking-glass; light purple.
4. Ran's born; yellow, the pod its beauty.
5. Venus's navel-wort; clear white.
6. Round snacks; yellow, and singular pod.
7. Dwarf variegated lysich; crimson and white.
8. Heart's ease; purple and yellow.
9. Half moon; or morning-glory; white, and singular pod.
10. Blue meadow lysich; sky-blue.
11. Dwarf virgin's stock; purple.
12. Small hedgehog; yellow, and singular pod.
13. Woodroof; light blue.
14. Red hawkweed; pale red.
15. Large hedgehog; yellow, and singular pod.

Second range, which grow from 12 to 18 or 20 inches high.
16. Oak of Jerusalem; yellowish, with fragrant smell.
17. Small white candytuft; clear white.
18. Long-horned devil in a bush; yellow, and singular pod.
19. Cornflowers minor; bright blue, with yellow eye.
20. Large purple candytuft; light purple.
21. White salvia's candytuft; flesh-red.
22. Annual snapdragon; purple and yellow.
23. Large white candytuft; clear white.
24. Scarlet, or crimson, and light red.
25. Striped convolvulus minor; blue and white.
26. Yellow convolvulus; clear yellow.
27. Dwarf nasturtium; deep orange.
28. Broad Spanish nigella with brown seed; deep blue.
29. Red false adonis; dark red.

Third range, which grow from 20 to 24 or 25 inches high.
30. Spanish nigella, with black seed; light blue.
31. Double broad-leaved cornflower; pale-blue, and purple eye.
32. Blue Moldavian balm; deep blue, and fine scent.
33. Annual red-baron; pale red.
34. Double Roman nigella; white mixed with blue.
35. Small running nasturtium; dark orange.
36. Nasturtium major; yellow, mixed smell but to the curious.
37. Dwarf larkspur; pink and white.
38. Sweet-scented lupines; bright yellow.
39. White Moldavian balm; fair white, and fragrant smell.
40. Dutch lupines; fine blue.
41. Annual hare's ear; pale yellow.
42. Plectranthus; pink and purple, and yellow eye.
43. Dutch ranunculus-marigold; sulphur-color.
44. Red-topped clary; pale-red, and pink leaves.

Fourth range, which grow from 2 to 2½ or 3 feet high.
45. Belvedere; yellowish, a handsome plant.
46. Double upright larkspur; blue, bluish, &c.
47. Double upright larkspur; blue, bluish, &c.
48. Cornus minor; blue, crimson, &c.
49. Thorn-apple; white, and singular pod.
50. Prince's feather; dark crimson.
51. Crown-larkspur; pale pink, spotted, &c.
52. Honey scabious; pale blue, and globular pod.
53. Parnassian; crimson, and deep red.
54. Small blue lupines; bright blue.
55. Loves lie-a-bleeding; light red.
56. Ranunculus-marigold; deep orange.
57. Honeywort; dark purple, and singular shade.
58. Strawberry; bright-red fruit.

Fifth range, which grow from 3 to 4 feet high.
59. Venetian small-flowered mallow; purplish-white.
60. Double crimson j Ragged-leaved poppy; dark crimson.
61. Tall narrow-leaved wallflower; bright yellow.
62. Arab; deep crimson.
63. Double striped carnation-poppy; red and white.
64. Tall sunflower, or, calendula; deep red.
65. Blue sweet tropfell; lead-color.
66. Red lavaters; light changable red.
67. Branching larkspur; blue and white, &c.
68. Tall white lupines; clear white.
69. Double black carnation; dark purple, and rose-color.
70. & 71. Small Persian nasturtium; dark orange.
72. Dwarf Maltese cornflower; dark yellow.
73. White lavaters; snow white.
74. Dwarf double and quilled yellow sunflower; deep yellow.
75. Bladder ketmia; pale - sulphur and purple eye, with singular pod.

Sixth range, which grow from 5 to 7 or 10 feet high.
76. Tall yellow globe flowers; with black seed; deep yellow.
77. Painted lady sweet-scented peas; pale red, and white.
78. Arab; sulphur-colored.
79. Purple sweet-scented peas; dark and light purple.
80. Tall Indian arsamt; bright crimson.
81. Painted lady crown-peas; black and white.
82. Convolvulus major; fine purple.
83. White convolvulus; pale white.
84. Large Indian nasturtium; dark and light orange.
85. Tall double bristlyflower; sulphur-colored.
86. White sweet-scented peas; clear white.
87. Plain tangier peas; fine crimson.
88. Spanish Major; bright red.
89. Painted lady tangier peas; pale red and white.
90. Scarlet balsam; scarlet.
91. Cutleaf-upright mallow; white tinged with purple.

6510. In borders he sows in six rows, or rather at six different distances from the walk, according to the different ranges, thus:—

<table>
<thead>
<tr>

</tr>
<tr>
<td>Fifth</td>
<td>16</td>
</tr>
<tr>
<td>Sixth</td>
<td>1</td>
</tr>
</tbody>
</table>

6511. For a circular clump, or cone of flowers, including all the 89 different sorts, he arranges the six heights in six concentric circles (fig. 616), placing a persicaria and oriental mallow in the centre. The general appearance (fig. 617), he says, is "the same on every side, rising gradually from the edge upwards, the highest plants meeting nearly in a point at the centre, and no two flowers of the same color or shape being seen together." (Beauties of Flora, &c. p. ii.). To those who have but a limited space and means, or who have few perennial flowers; to persons in remote situations in the country; to residents in the colonies; and to female and infant gardeners, the above list and modes of arrangement afford a source of considerable show and amusement at a very small expense, little trouble, and being annuals, little loss of time. Swindon was in the habit of supplying masters of ships with packets of these seeds for all parts of the world.
SUBSECT. 5. Species and Varieties of Half-hardy annual Border-Flowers.

6512. HALF-HARDY ANNUAL BORDER-FLOWERS, FLOWERING IN JULY, AUGUST, AND SEPTEMBER.

Height from 0 to 1/2 of a ft. From 3 of a foot to 1 1/4 feet. From 1 1/2 to 2 1/2 feet. From 2 1/2 to 5 feet. From 5 feet upwards.

6513. Propagation and culture of half-hardy annual flowers. These are raised from seed, which is sown in March in a hot-bed; and the plants, when an inch or two high, are transplanted into another bed of very moderate temperature. Here they may remain till the middle of May, or till all danger from frosty nights is over, and be then transplanted to where they are to flower in the borders, and treated in all respects as hardy annuals.

6514. To save seed. In dry seasons, most sorts will ripen seeds, if permitted, but in wet seasons, unless the plants have been well forwarded in spring, and planted in a dry soil and warm situation, the seed will not be matured. In such cases, a hand-glass supported over the flower is of use; or some may be removed with balls into large pots, and placed in an airy pit, frame, or greenhouse. In the northern and western counties, where the climate is cold and moist, half-hardy annuals never ripen their seeds in any year; and supplies are therefore annually obtained from the London seedsmen.

SECT. III. Flowers for particular Purposes.

6515. The particular purposes to which flowers are sometimes applied, may be either the concealment of local defects, or the production of local beauties. Among the former may be classed, covering naked walls, posts, parts of ruins, or other upright objects; concealing horizontal defects, as naked sub-barren spots, unsightly banks, &c., producing vegetation under the shade and drip of trees: among the latter, ornamenting water with flowering plants; ornamenting rocks, or assemblages of stones formed in imitation of rocks; preserving a green appearance on beds or borders during winter; forming edgings to beds or borders; furnishing odors; and presenting botanical, curious, and scientific assemblages.
SUBJECT 1. *Flowers which reach from five to seven feet in height, for covering naked Walls, or other upright Deformities, and for shutting out distant Objects which it is desirable to exclude.*

6516. *The flowers suited for covering upright deformities* are the climbers and twining plants: the former to be supported by spray or trellis-work, or nailed in the manner of wall-trees, and the latter by rods. We shall select a few species of each from the plants already enumerated in the foregoing section, to which the botanist will easily be able to add others from the more extensive catalogues.

*Subsect. 2. Flowers for concealing Defects on horizontal Surfaces:* as naked sub-barren Spots, unsightly Banks, &c.

6517. *The flowers suited for covering horizontal deformities* are creepers and trailers, of which we shall here bring together the names of the most common sorts:—

6518. *Flowers which will thrive under trees* are of particular value. In improving neglected flower-gardens and pleasure-grounds, it is a common complaint that new things cannot be brought forward on account of the shade and drip of trees. This section, and the corresponding one of hardy shrubs, will, it is hoped, aid in removing that complaint, which can only have arisen from ignorance of the native habitations of plants. It is proper to observe, however, that there is scarcely any, indeed we may say, no plant, that will thrive under a dense evergreen fir-tree clothed with branches down to near the surface: moss is all that can be there expected; or, if somewhat open, the pyrola, box, and juniper will exist. Where trees are so dense, however, no plant or shrub can be desired under them.

The same as for herbaceous plants, taking into consideration the difference in the soil and site.

**Subsect. 5. Flowers for ornamenting Rocks, or Aggregations of Stones, Flints, Scoriae formed in imitation of Rocky Surfaces, &c.**

6254. In strict propriety, mountain or rock plants only should be introduced on artificial rock-work; but natural mountains and rocks are always moist and cool, and the plants which have their habitats there would not always thrive on dry ridges of earth and stones. On a small scale, therefore, choice is generally made of such plants as are not tall and rampant, and as grow naturally in a dry soil. In the following list, as in the others, the most ornamental of them are distinguished by a letter (d), and those which flow greater the summer by a figure (2), &c.

**Perennials.** Achillea alpina 5, montana, Ajuago alpes, pyrenealba 5, Alchemilla alpina, pentaphylla, Alyssum montanum, Anthyllis alpina, aquatica, aestiva, alpina, aphana, baderenii, pauletii 3, p. major 3, Anthemis montana, Anthyllis alpina, Arabis alpina 3, bellerofonii 3, beata, vulgaris, Bergenia beccabunga, Becheria colchica, belladonna, Bergenia aquatica, bergenica, Korneliana montana, ciliata, bergenia, annua, bergenia, bicolor, Bergenia callosa, Bergenia reptans, Bergenia astilbe, bergenia, longifolia, Bergenia ciliata, bergenia, pinnata, Bergenia purpurea, bergenia, regina, Bergenia veitchii, bergenia, marginata, Bergenia difformis, Bergenia stellata, Bergenia speciosa, Bergenia straminea, Bergenia magellanica, Bergenia frutescens, Bergenia capillaris, Bergenia pendula, Bergenia horrida, Bergenia hirsuta, Bergenia stolonera, Bergenia rupestris, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornuta, Bergenia cornu
FLORISTS FOR PARTICULAR ROSES.

**Subsect. 7. Flowers for Edgings to Beds or Borders**

6598. The principal plants for edging, next to the dwarf-box, are the statiche armeria, bellis perennis, gentiana acutla, saxifraga umbrosa, oppositifolia, hypnoides, festuca ovina, and other low-growing evergreens; but all the following sorts may be used in extensive concerns requiring edgings of flowers. The common and other heaths make very beautiful edgings in parterres of peat soil.

**Subsect. 8. Highly odoriferous Flowers.**

6593. Flowers with sweet smells are no less desirable than those with fine forms or colors. So little has hitherto been done in the nomenclature and classification of vegetable odors, whether fixed or volatile, that we can hardly submit any thing satisfactory on the subject. No small part, however, of the pleasure derived from flowers depends on their odors; and that these are very different, every one must have re- marked who has walked in a wood or a garden after a warm shower, or in a dewy summer's evening. Perhaps the best mode to arrange the odors of plants in our present imperfect state of knowledge on the subject, would be to fix on some generally known smells, as those of the rose, lily, thyme, &c. and group the others under these in the way of natural orders; and thus we should have rosodore, liliodore, thymerode, tymerofone, &c.; but in default of some such, or any system, we shall here bring together a few names under common received distinctions.

**Subsect. Other selections of Flowers.**

6590. Other selections will readily occur to the florist who is conversant with the ample store of plants at his command; such as double flowers, flowers that continue in blossom the greater part of the year, flowers for peat soils, &c. all which he may select from the indications in the tables already given. He may also select, according to the Linnean or natural orders, by referring to the tables (588. and 589.) in which the genera are so arranged; or according to the native habitations, native country, year of introduction, or rarity, which circumstances he will find noted in the excellent catalogues of Sweet and Page.

**Subsect. 10. Botanical and other Assemblages of Plants.—Dial-Plants, Parasites, Ferns and Mosses, Alpines, and a selection for a small garden.**

6591. Botanical collections, as well as cabinets of shells and minerals, have been in vogue by the curious since the most remote times. In many private families there is one, or more, of the hardy plants of the vegetable kingdom, as far as they are introduced into this country, are arranged in their order according to some system; and either in narrow beds, in which one species follows another, or in groups, on lawn or gravel, in which the species most nearly allied according to the system adopted, are placed together, each group containing an order, genus, or family, and all the orders of a class forming a constellation of groups, connected at one point with the preceding order, and at another with that which follows. Sometimes a different arrangement is adopted, and all the plants that can be considered as ornamental are assembled in beds or borders, or both, and all those that are curious, as the hoons, mosses, fungi, &c., or useful in agriculture or the arts, as the grasses, garden-plants, plants used in dyeing, tanning, &c. are arranged in beds or groups in compartments by themselves. This is in general the most suitable mode for a private garden. With respect to the species to be introduced in these groups, the gardener will have recourse to the tables already referred to, in which, in the Jussieuian table (590.), under Gramineae, Cy- peraceae, Juncoce, Rosticaceae, he will find all the grasses; under Flios, all the ferns; under Lycopodium, the plant-mosses; under Equisetaceae, the equisetum, &c. The economical plants he will find under general heads in our view of the divisions of the British Flora (574.), and the species he will find enumerated, and classified, in our Encyclopaedia of Agriculture.

6592. Dial-plants. Among curious collections, it may sometimes be desired to assemble the dial-plants, or such as indicate the hours of the day. An ample list of these has been given by Linneus, in the Philosophia Botanica; the following are plants generally known and easily procured, may be deemed sufficient to complete a botanist's dial in Britain:—

CATALOGUE OF HARDY TREES.

Chap. IX.

Catalogue of Hardy Trees, with Showy Flowers.

6539. All trees may be considered as ornamental by adding to the beauty of landscape; but we mean here to confine ourselves to such as are ornamental, by the conspicuousness of their flowers. These are not numerous; they are all of the deciduous kind, and their time of inflorescence is limited to two or three months. The principal are the horse-chestnut, acacia, the fruit-trees in their wild state, some species of mespilus, sorbus, cytisus, robinia, &c.; these, with some others, we have arranged according to their height and time of flowering, in order to admit of a selection for the back rows of the shrubbery. None of the few evergreen trees which we possess, have showy flowers, but we have added the names of these, with their heights, to facilitate a selection for mixing with the deciduous sorts in the mingled or grouped shrubbery. We have omitted all those showy flowering and evergreen trees which do not usually attain the height of twenty feet, deeming it more suitable for our purpose to include them among the shrubs of that size. All the useful and curious species of trees will be found in Page's Prodrumus, with their heights, time of flowering, soil, mode of propagation, and other circumstances. In the Articular Catalogue (Part III. Book III. Chap. VIII.), the most useful timber-trees are described, and the shapes of trees, and their colors, and characteristic expressions, are treated of both under Articular and Landscape Gardening. (See Part III. Book III. Chap. II. Book IV. Chap. II.) Much less attention has of late been paid to the introduction of new sorts of trees into this country, than to the introduction of fruits and flowers. The French and Germans seem to excel us in this respect. A considerable number of new sorts of

3 L 4
ornamental trees have lately been added to the British Arboretum, by Messrs. Loddiges, and specimens of them are conspicuously arranged in the Hackney nursery, to show their forms and characters.

Propagation and culture. See Arbiculture. Most of the trees enumerated in the foregoing sections are highly ornamental as single objects on a lawn; and form curious chamber plants when dwarfed and potted in the Chinese manner. (Hort. Trans. iv. 280.)

---

**Chapter X.**

**Ornamental Shrubs.**

6542. *The ornamental shrubs are a much more numerous tribe than the trees: we shall first notice the more select sorts, as the rose, rhododendron, althea, &c. and afterwards, in succession, the deciduous kinds, evergreens, creepers, and sorts for particular purposes.*

**Sect. I. Select Shrubs.**

6543. The term *select shrubs* we apply to such shrubs as have been much cultivated, and of which numerous varieties are recognised as beautiful.

6544. *The rose is known by every body at first sight, and has been a favorite flower from time immemorial among the civilised nations of Europe and Asia. The shrub varies in size in different species, from one foot to six or eight, and the colors are red, white, yellow, purple, black, striped; simple, or in almost numberless shades and mixtures; and single, semi-double, and double. It is cultivated in every garden, from that*
of the most humble cottager upwards; some species, as *R. centifolia damascena,* &c. are also cultivated by commercial gardeners on a large scale for distilling rose-water, and for making *attar,* or essential oil of roses. Six pounds of rose-leaves will impregnate by distillation a gallon of water strongly with their odor; but a hundred pounds afford scarcely half an ounce of *attar.* The rose is also used in medicine. Botanists are not agreed as to the number of original species of this genus, some regard all the European species as originated from one source; others, and especially the moderns, divide them into species, subspecies, and varieties. The most scientific work which has appeared on the roses in England, is the *Rosarium Monographiæ* of Lindley, 1819, in which above a hundred species or subspecies are described, and some of them figured; and Miss Laurence has published ninety plates of *A Collection of Roses from Nature,* 1810. In France, Guillemaud has published *Histoire Naturelle de la Rose,* 1800; and Redouté and Thory are engaged in a splendid work, in folio, entitled *Les Roses,* containing plates of all the known species and varieties of this flower. Thory has published a separate tract on their culture, entitled * Prodrome de la Monographie du Genre Rosier,* &c. 1820; Pronville, a *Nomenclature Raisonnée,* in 1818; and Vibert, *Observations,* &c. in 1820. A copious and intelligent account of the Scotch roses has been lately given by Sabine (*Hort. Trans.* iv. 231.), and some hundreds of new varieties have flowered from seedling plants, in the nursery of Lee, and will soon be found in his sale-catalogues.

6545. *Species and varieties.* The lists of the London and Paris nurseries contain upwards of 500 names: that of Calvert and Co., Englishmen, who have established a nursery at Bonne Nouvelle near Rouen, enumerates near 900 sorts. The greater part of these have been raised from seed on the continent, where it ripens better than in this country, within the last thirty years. A number of varieties have also been raised in Britain, especially of the *R. spinosissima,* or Scotch rose, of which above 500 varieties are procurable in the Glasgow nursery. New varieties are raised in France and Italy annually; Villaresi, royal gardener at Monza, has raised upwards of fifty varieties of *Rosa indica*; not one of which have, as far as we know, reached this country. Some of them are quite black, others shaped like a ranunculus, and many of them highly odoriferous. The following table contains nearly 150 species and varieties of single roses, of longest standing, arranged according to their time of flowering, heights, and colors; and of the greater number of which there are double and semi-double varieties of the same colors. The names are chiefly taken from Page's *Prodromus,* and the plants are known by them in the Hammersmith nursery. Ample lists, as already observed, may be had from all the principal nurseries, and the best mode of making a selection is to view the plants while in flower.

### JUNE.

### JULY.

### AUGUST.
6547. *Propagation.* By seed for new varieties, and chiefly by layers for continuing approved sorts. They are also multiplied by budding, cuttings, and suckers. 

6548. *By seed.* Ripe hips containing the seeds are obtained from semi-double and single flowers, and to increase the chance of new varieties, these should be taken from plants that have been propagated among, or near to the sorts of which a cross is made. We are not in doubt that Knight's enterprise of extracting the stamens of the one parent, and dusting the anthers of the other, has been applied to the rose, but there can be no doubt it might be done in many instances. In France and Italy, the usual mode is to form a plantation of double and semi-double sorts mixed indiscriminately, and take the result of the crossing by picking the hips of the crosses. Gulliver's varieties are adopted by this method, but Villaresi raised most of his beautiful varieties of the *Rosa indica,* by planting them among as many varieties of European roses as he could procure. Austin, nurseryman at Glasgow, and Lee of Hammersmith, mix all the sorts of Scotch roses in the plantation. The other mode may be called mating at random, and this to random-in and in-breeding.

6549. *Process.* Few of the hips are ripe before October, but most sorts that come to maturity in this country, will be fit to gather by November. The seeds of the rose require to be one year in the soil before they will root or grow up. The soil or earth, when the hips have been perfectly rotten, and the seed being separated and sown in February, will come up in the May or June following. The best place to lay up the hips is the floor of a cellar, such as that used for storing roots; but in whatever way they are preserved, they must be kept perfectly dry as they are in a dormant state, and kept from all moisture until the seed is shed. By this means the seed is ready for spring, for which time they are sown. The ground is prepared by digging deeply, to a depth of five inches, and to the depth of the hip; and having done this it is necessary to add a few inches of sand, or other dry material, to prevent the seed from being washed out of the soil. The seed will germinate in spring, if sown in a warm greenhouse, or at a temperature of 70° Fahr., in the open ground. 

6550. *By layers.* The common mode is to lay down the young shoots of the preceding summer late in autumn, or early in the succeeding spring, and then, with the aid of the gardener's needle, to wound the rose and make it adhere to the earth. 

But it is now found, that if the same shoots are laid down when the plant is beginning to flower in July, they will, with a few exceptions, produce roots and be fit to remove the same autumn, by which a whole year is gained. Such sorts as do not root in one year, may be planted or till the following spring when the shoots are neither long or in a dormant state, and furnished with healthy leaves, root much more freely than shoots of ripe wood. After the plants are removed from the stool, they are planted in nursery rows, and in a year, the blossom-buds having been carefully pinched off from the first laying down, they will be fit for removal to their final destination. The stools are then to be pruned, and the soil stirred and enriched on the general principles already laid down. (1804.)

6551. *By suckers and dividing the roots.* Many of the common sorts admit of being rapidly multiplied in this way; and the plants obtained may be planted in their final destination at once.

6552. *By cuttings.* Most of the sorts might, no doubt, be propagated from cuttings of the young wood; cut at a joint where it is beginning to ripen, and planted in sand and vegetable mould under a hand-glass. But this mode is only adopted with such sorts as strike easily, as the *R. indica,* and other eastern species.

Some of the later roses is admirable cuttings, and the rose buds are difficult to propagate by layers; for it is found, that plants so originated, even though on stocks of the hardier sorts, are less durable than such as are raised by any of the other modes. But the chief use of budding in the culture of the rose is to produce standard roses, or to produce several sorts from the same stock. Standard roses are a modern invention, and it is generally supposed of the Dutch, first carried to Paris, and about twenty years ago to England. They are highly artificial objects, of great beauty, and form magnificent ornaments to parterres and borders. The stalks are either of the tree-rose (*R. fillosa,* W.); or of any sorts of woody wild roses, as *R. scabriuscula,* *heterophylla,* or *suroleusa,* Sm. They are budded at different heights from three to seven feet, but commonly between five and six feet from the ground. A stock in the Paris garden, which carries several sorts, has a naked stem of nearly fifteen feet, and there are others at Malmaison and the Grand Trianon, of equal height. The stocks of these roses are in London, in large pots, and at various places, are often budded the same summer, sometimes in spring by the scalope mode of budding (2059), *Pomme poussant* of the French; and never later than the succeeding spring or summer by the common mode, *Pomme dormant,* Fr. Generally the buds are inserted on the stem two or three inches from the top, and the eyes are inserted in alternate positions on the upper six, or twelve inches of the stem. Every stock is supported by a rod, which should reach a foot or eighteen inches higher than the situation of the bud; to this rod the stock is tied, and afterwards the shoots from the buds, which are otherwise liable to be blown out by high winds. They are presently covered by other shoots that are prepared in the same manner, and having a better climate, and more experience in the culture of roses, excel us in this department of rose propagation, and their standards afford an article of commerce with other countries. Their common plants, raised by layers, are also obtained in large demand, but from these are usually, if not in proportion to the number of standard roses from Paris, may be seen in the Hammersmith nursery, in the Comte de Vande's garden at Bayswater, in the Duchess of Dorset's at Knowle, and at various other places.

6554. *Final situation.* No species of rose, wild or cultivated, thrives well in or very near large towns, on account of the smoke and confined air. The yellow and Austrian roses (*R. lutea* and *L. bicolor*) are difficult to flower in any situation, but seldom or never blow in the suburbs of London: even the monthly rose does not thrive so well there as at some miles distance in the country. Roses are generally planted in the front of shrubbery, and in borders; they are also planted by themselves in rose-gardens or rosaries (fig. 620.), in groups on lawn or gravel, either with common box or other edgings, or with edgings of wire, in imitation of basket-work. These last are called baskets of roses; the ground enclosed in the basket-margin is made convex, so as to present a greater surface to the eye, and increase the illusion; the shoots of the stronger sorts are layered or kept down by pegs till they strike roots into the ground, so that the points of the shoots furnished with buds appear only above the soil, which is sometimes covered with moss or small shells. Under this treatment, the whole surface of the basket becomes, in two or three years, covered with rose-buds and leaves of one or various sorts. Where one of the larger free-growing sorts is employed, as the moss, or any of the Provence (rose de cromeois, Fr.) varieties, one plant may be trained so as to cover a surface of many square yards. Where different sorts are introduced in
the same basket, they should be as much as possible assimilated in size of leaves and flowers, and habits of growth, and as different as possible in the colors of their flowers. By mixing small-flowered with large showy sorts, the beauty of the former is lost without adding to the effect of the latter.

6555. In rosaries commonly but one plant of a sort is introduced, and the varieties which most resemble each other are placed together, by which their distinctions are better seen. Particular compartments are often devoted to one species, as the Scotch, Chinese, yellow, burnet-leaved, &c. which has an excellent effect; sometimes a piece of rock-work in the centre is covered with the creeping roses, and on other occasions these are trained to trellis-work, which forms a fence or hedge of roses round the whole. In this hedge, standard-roses are sometimes introduced at regular distances; a grove of standards is also frequently formed in the centre of the rosary, and sometimes they are introduced here and there in the beds.

6556. Standard roses, however, have certainly the best effect in flower-borders, or when completely detached on a lawn: their sameness of form, and that form being compact and lumpish, prevents them from grouping well, either among themselves or with other objects. Their beauty consists in their singularity as rose-plants, and in their flowers; and, therefore, to display these beauties to the best advantage, they require to be seen singly, or in succession. This is the case where they occur as single objects on a lawn, or in the centre in, and here and there among, groups of flowers; or in lines or avenues, along flower-walks. In the gardens of the Grand Trianon, they are planted profusely in large masses, like plantations of trees and shrubs, and there much of their individual beauty is lost, and no good general effect produced.

6557. Soil. Most species of the rose in their wild state grow in sandy and rather porous soil, excepting such as are natives of woods, where the soil is richer, and comparatively moist. But all the cultivated roses, and especially the double-flowering kinds, require a rich loamy soil, inclining to clay rather than sand; and they require also, like most double flowers, plenty of moisture when in a growing state.

6558. General culture. To produce strong flowers, roses require some attention to pruning; old wood should be yearly cut out, and the young shoots thinned and shortened according to their strength, and whether number or magnitude of flowers be wanted. Those sorts which throw up numerous suckers should be taken up every three or four years, reduced and replanted; and most sorts, excepting the standards, will be improved by the practice, provided attention be paid to remove a part of the old soil, and replace it by new. The points of the shoots of the more delicate sorts of roses are very apt to die when pruning is performed in winter or spring; to avoid the consequences of this evil, many give a second pruning in June, or do not prune the tender sorts at all till the beginning of that month. A very good time for performing the operation is immediately after the bloom is over; cutting out old exhausted wood, shortening shoots which have flowered to a good good accompanied with a healthy leaf, but leaving such shoots as are still in a growing state untouched till October. Where very large roses are wanted, all the buds but that on the extreme point of each shoot should be pinched off as soon as they make their appearance, and the plant liberally supplied with water. To lessen evaporation, and keep up a constant moisture at the roots of their roses, the Paris gardeners generally mulch them with half-rotten stable-dung, or partially rotten leaves.

6559. Forw.arding and retard.ing roses. The earliest flowering rose is the monthly, which, in mild seasons, and planted against a wall, will sometimes flower in the beginning of April; the roses next in succession are the cinnamon, which flowers in May; the damask, in the end of May or beginning of June; the blush, York and Lancaster, Provence and Dutch hundred-leaved, in June, July, and August. The Virginia and musk roses are the latest European sorts; they flower in September, and in shaded situations will sometimes continue in bloom till the middle of October; but the earliest rose (the monthly) is also the latest, and generally continues flowering till interrupted by frost. The earliest sorts may be materially forwarded by being planted against a south wall, and if portable bushes are placed before them, and the wall is either flued and heated by fires, or a lining of thin placed behind, the plants may be brought to flower in February or March. The monthly rose being protected by glass in autumn, or aided by artificial heat, may be continued in bloom till Christmas. A very common mode of obtaining late roses, and one of the greatest antiquity (48), is by cutting all the flower-shoots off when the buds begin to appear, or by rubbing off all the rudiments of shoots, of every kind, early in spring; a second crop is in consequence produced, which will not be in a state to bloom before the autumn.

6560. Forcing the rose. The best sorts for this purpose are the common and moss Provence; the Indian sorts force well, or rather, in stoves, continue in bloom all the year; but the commoner varieties of these not being fragrant, they are in less repute than the European roses. Rose-plants should be a year in pots previously to the autumn when it is intended to force them; they should be planted in pots of six or eight inches' diameter, in rich loam, and plunged in an open airy situation; their flower-buds pinched off as they appear; and the plants put early into a state of rest, by excluding the sun and rain, but
not a free circulation of air. Abercrombie says, "There is no certainty of attaining a fine blow of roses in the depth of winter by the most expensive artifices of forcing; and yet fine flowers may be produced early in the spring by any ordinary stove put in operation in December. When the plants are first introduced, keep the air of the house at about 50°, never letting it fluctuate to more than two or three degrees below or above. In the second week, aim at 60° as the standard; in the third week at 65°. When a month has nearly elapsed, begin to increase the heat gradually to 70°; having brought it to this standard, let it afterwards exceed it from three to five degrees, rather than sink below. A succession may be kept up by introducing some pots every eight or ten days."

6561. Insects. All the species of roses are very liable to the attacks of insects, especially of the aphides; some, and especially the briar and Scotch rose, are attacked by the Cynips rosae, which, by puncturing the bark, occasion the production of rose-galls, and of those moths often seen on wild roses, which were known formerly under the name of Beleguar, and used in medicine. A great number of insects seem fond of the flowers of roses, from the appalling carwig (Porcellio auriculata) to the lady-bird (Hattgarda) (which generally lays its eggs on leaves or shoots of roses, and the larvae (a) in the leaves of various species, both wild and cultivated. There seems no remedy for insects on plants in the open air so simple and effectual as gathering them by hand, or removing the leaf or that part of the shoot which is infested by them. Under cover, tobacco-smoke will go a great way to drive away them."

6562. Of select American shrubs there are numerous species and varieties, both deciduous and evergreen, which will be found arranged according to their heights and colors in the two succeeding tables, and those requiring a peat-soil distinguished by a letter (p). They are all highly valued for their flowers, which are large and magnificent in magnolia and rhododendron; odoriferous in azalea and daphne; and beautiful in andromeda, Vaccinium, Andromeda, Erica, Daphne, and various others.

6563. Propagation. They are all propagated by seed or by layers; though grafting or inarching is resorted to in some cases as more expeditious. The seed is either procured from America, or saved in this country, and being very small, is sown as early as possible in pans of peat-earth, and placed in the shade. In winter it is placed under a cold-frame, or otherwise protected from the frost, and the plants come up in May or June. In the following autumn, or succeeding spring, they are pricked out into other pots, or into beds of peat-earth in a shady situation. Here they are protected by hoops and mats during winter; and in two years are again transplanted into a similar soil and situation, and at distances corresponding to the size of the leaves, or habits of the plants; here they remain till they flower, or till wanted to be removed to their final destination. They commonly flower from the fourth to the seventh year.

6564. By layers. The young shoots only are used for this purpose, either laid down in June and July, when in full growth, or in the following autumn; by the former plan a year is gained, as the shoots will be rooted, and may be removed by the succeeding winter or spring. Some sorts of magnolia, rhododendron, &c. require two years to form a sufficient number of roots. The plants, when removed, may be planted in fine and well watered, in a proper situation; and protected the first winter by mats; or, they may be planted in pots, and receive, during winter, the protection of a frame. They are brought on in pots a year before wanted, which admits of their being placed in position with respect to the shoot being inarched. The daphnes and arbutus ardrachne, are generally grafted with detached scions.

6565. By cutting. Some of the azaleas, heaths, &c. may be multiplied by cuttings of the young shoots, when in a growing state, taken off where the wood is beginning to ripen, and planted in sand and peat. This operation is performed in May. If this is done, and the weather favorable, the shoots will be ready to remove into prepared beds, or to plant in small pots by the middle of September.

6566. By grafting, budding, or inarching. This is practised with some sorts of magnolia, arbutus, daphne, &c. which are placed on stocks of harder species of the same genus, as on M. purpurea, A. undulata, D. officinalis, &c. The stocks are planted in pots a year or two before wanted, which admits of their being placed in position with respect to the shoot being inarched. The daphnes and arbutus ardrachne, are generally grafted with detached scions.

6567. Culture. The culture requisite for American plants, Abercrombie observes, "principally consists in providing some imitation of the original soil, in order that they may flourish in full vigor; and, where there is no factitious soil provided, in making a compensation during the dry part of summer, by plentiful waterings. Most of the exotic shrubs brought from America, were originally found growing on tracts of ground resembling our beds of peat, except that the alluvial soil there extends along a greater surface, and the body of vegetable mould embossed in the swamp is richer and deeper, being on a scale corresponding with the magnitude of the rivers. The native plants found in these situations, vegetate with the highest vigor and luxuriance. The soil in many parts is so pervaded by vegetable substances, that where from any cause a section of the solid ground occurs, as in the bank of a river, or the shaft of a well, a layer of decayed logs, branches, and leaves of trees is uncovered to the spectator. The luxuriance of the vegetables may, however, partly be ascribed to the excessive moisture which is peculiar to the climate of America. In a few places, indeed, on the western coast, rain is not known; but the soil there is, in general, copiously watered by dew, so as to render it highly productive. In the season called winter by the natives of South America, lasting from May to November, a continued succession of impetuous rains gives to the plains, in most places, the appearance of an ocean. When the rains have ceased, the humidity
of the climate is kept up by a constant evaporation from swamps, rivers, and lakes, the largest in the world. As we cannot have the mitigated warmth of the climate of South America in plantations, in the full ground, and as the temperature of our winter cannot be expected to coincide in its effects with the corresponding season even of North America, when so many local circumstances are different, it is neither indispensable, nor perhaps advisable, to create an artificial swamp for the cultivation of many American plants. It is mostly safer to confine the efforts of imitation to the kind of earth, unless the water can be carried off at any time; for the lodgment of wet might cause some kinds of roots to perish in cold weather. Thus the andromeda arborea would be injured by being floated in winter, and must be protected from frost, though it requires a deal of water in summer. The great object is to imitate the American peat. This is a composition of the branches, twigs, leaves, and roots of trees, with small plants, grass, and weeds; by having lain immemorially in water, the whole is formed into a soft mass, and, when the materials are completely decayed and blended so as to be homogeneous in appearance, the compound is the finest vegetable mould; where this description of peat cannot be obtained, recourse must be had to the best that can be procured from marshes, bogs, or heathy commons, which must be well turned and sweetened, and mixed with sand and rotten leaves or dung. The soil being procured, the next thing to be done is to form a stratum of it of sufficient thickness in the site intended for the plants. When they are merely to remain a year or two, this need not be above a foot in depth; but where they are to remain permanently, it should be at least three feet thick. To encourage the roots to penetrate the native soil, the bottom of the excavation should be dug and mixed with peat; unless a bottom of rough gravel were substituted at the depth of four feet, and such an arrangement made, as that water could be introduced to, and withdrawn from, this layer of gravel at pleasure, so as to saturate the whole superstratum of peat. In level situations, and where water was abundant, this plan might be readily adopted, and none could more closely imitate nature, as, by keeping the surface of the peat a few inches below the level of the natural ground, the water might be allowed to rise a few inches above the peat, and inundate the whole surface of the American ground. In peat countries, and where the climate is moist, as in Lancashire and Cheshire, admirable contrivances of this kind might be adopted, and the American and bog-earth plants, herbaceous as well as shrubby, grown to the greatest perfection.

6569. Final situation. American and peat-earth shrubs, requiring large masses of their peculiar soil, and frequent artificial waterings, cannot conveniently be introduced in mingled borders or shrubberies. They are therefore generally planted by themselves in beds or compartments of peat-earth; or entire gardens or shrubberies are devoted exclusively to them. This last mode appears decidedly the best, as the general habits and appearance of American peat-earth plants, independently of their culture, do not harmonise remarkably well with European species. An American garden may have a northern or eastern exposure, and if it slopes considerably will be still less affected by the warm dry weather of summer. It may be laid out in any of the different styles of flower-garden (figs. 541. to 545.); herbaceous plants introduced as well as shrubs, and the whole surrounded by a sloping phalanx of American trees. The sorts may either be arranged in the mingled manner (6139.), or grouped or classed according to some system. (6141. to 6150.) Many and indeed most of the American shrubs thrive under the partial shade of lofty deciduous trees, and the leaves which fall from these protect their roots both from the frosts of winter and the drought of summer, while they constantly decay into vegetable mould, and thus at the same time afford a supply of nourishment. Hence, in some cases, the hardier sorts of rhododendron, azalea, andromeda, &c. may be introduced as undergrowths in the margins of thin woods, placing under each plant a cubic yard or more of its proper soil. This mode of planting, it would appear (Mason on Design, art. Pitt), was first adopted by the great Earl of Chatham; but it has been carried to the greatest extent, not only with American plants, but with roses and other tender shrubs, in the extensive woods of Fonthill, where, as also at King’s Weston near Bristol, Kenwood at Hampstead, &c. many of the plants shed their seeds, and young rhododendrons and azaleas spring up in abundance. In the nurseries, it is a general practice to keep American and other peat-earth plants in pots, and to protect them during winter in frames and pits for convenience of deportation. At the Hammersmith nursery, one green-house is exclusively devoted to evergreen magnolias. All the American and peat-earth shrubs may be selected from the three first tables in next section, by observing the indication of peat-soil (letter p); and the herbaceous peat-earth plants may be selected from the tables of Border-Flowers in a similar manner.

**Notes:**
- Amygdalus communis, and various species of Crataegus, L. (now Mespilus, Sm. and W.), may be referred to as examples.
- As our object is to form such arrangements as will afford most facility to the gardener in adjusting his plants as to height, color of the flower, and time of inflorescence, we have included all woody plants which do not exceed twenty feet in height under shrubs; and all those that exceed that height (excepting the climbers and twiners) we have allowed to retain their places in the tables of trees. Here, as before, the most ornamental species and those which continue longest in bloom are distinguished by appropriate marks (s and ♀).

6774. *The propagation and culture of shrubs being the same as that for trees, we combine both subjects in the catalogue of arboreiculture in the succeeding book.*

### SECT. III. Selections of Shrubs for particular Purposes.

6775. *The particular purposes to which shrubs, like flowers, may be applied, are the concealment of deformities or imperfections, and the production of particular beauties or desirable effects.* We shall here select the names of a few for concealing vertical and horizontal deformity; for producing an immediate effect as to bulk; for producing vegetation under the shade and drip of trees; for ornamenting water and rocks; for forming edges and hedges; for diffusing agreeable odors; for being ornamental by their fruit; and for economical or botanical purposes.

### SUBSECT. 1. Shrubs for concealing vertical and horizontal Deformities.

6776. *Vertical deformities* may either be concealed by the rapid and tall growing sorts (Subsect. 2.), or by the climbers or twiners, either deciduous or evergreen. The climbers may be nailed to a wall or fence, or tied to a trellis, or allowed to climb on branches and spray; for the twiners, tall sticks or poles are necessary.

6777. *Horizontal deformities* may be concealed by rapid-growing bushy plants, by allowing climbers and twiners to spread over them, or by the proper trailers and creepers of the hardest kinds, a few of which are these: —

- *Deciduous.* Rosa arvensis, Rubus fruticosus, Cissus hederacea, Cytisus subinquis, Genista decumbens, Rhamnus repens.
- *Evergreen.* Rosa sempervirens, Vinc a major and minor.

### SUBSECT. 2. Shrubs of rapid and bulky Growth.

6778. *Shrubs of rapid and bulky growth* are often desirable to produce immediate effect in laying out pleasure-grounds, as well as for producing shelter, and concealing objects.

- *Deciduous.* Cornus alba, alterniflora, floridana, Cytisus aveni.sus, Daphne mezereum, Forsythia viridissima, Spiraea salicifolia, Syringa vulgaris, Viburnum opulus.
- *Evergreen.* Cupressus sempervirens, Ligustrum vulgare, Myrtus communis, Podocarpus macrophyllus, Rhododendron ponticum, Sideritis scardica, Thuya orientalis, Ulex europaeus, var. hispanica.

### SUBSECT. 3. Shrubs which thrive under the Shade and Drip of Trees.

6779. *Shrubs which grow under the shade of trees* are found in practice to be a most valuable class for filling up blanks in old shrubberies, or screen plantations; and thus producing greenness, variety, and a healthy aspect, instead of emptiness, haggard stems of trees, or mere ghosts of plants.

- *Deciduous.* Cornus alba, alterniflora, floridana, Cytisus aveni.sus, Daphne mezereum, Forsythia viridissima, Spiraea salicifolia, Syringa vulgaris, Viburnum opulus.
- *Evergreen.* Cupressus sempervirens, Ligustrum vulgare, Myrtus communis, Podocarpus macrophyllus, Rhododendron ponticum, Sideritis scardica, Thuya orientalis, Ulex europaeus, var. hispanica.
Subsect. 4. Shrubs for planting by the Sides of Pieces of Water, or in Marshy Grounds, and among Rocks.

6580. Besides aquatic shrubs, most of the peat-earth species are also suitable for planting in marshy situations.

6581. Of mountain or rock shrubs the following are the some of the most hardy: —

**Deidendron**. Atraphaxis alpina, Daphne alpina, Comus decumbens, Lonicera alpigena, Onosia fruticosa, Potentilla fruticosa, Rhamnus saxatilis, Rhododendron dauricum, Ribes alpinum, Rosa alpina, spinosissima, Rubus cassinus, Syringa hispida, Spartium angulatum.

**Evergreen**. Arbutus alpina, Aralia procula, Daphne collina, Erica trunum nigricum, Erica, all the hardy species, Citrus, all the species, Gaultheria procumbens, Juniperus communis, Rosmarinus officinalis, Ulex europaeus, nana.

Subsect. 5. Shrubs for forming Edgings and Hedges in Gardens.

6582. Of shrubs for edgings few are comparable to the box (Berberis sempervirens var. nana); but some others may be occasionally used, as the

Andromeda polifolia, Arbutus alpinus and uva-ursi, Empetreum nigrum, various species of Erica, especially herbaeces, tetralix, vulgaris (Calluna, V.), Laven.

6583. Hedge plants. The following are a few of the numerous plants which may be used as hedges for shelter in gardens; almost all the free-growing sorts may be planted in rows, and cut in the hedge form; but the following sorts will form compact evergreen shelter: —

**Berberis** sempervirens, Juniperus communis, Laburnum alpinum, Ilex aquifolium, Ilex aquosiphon, Rhamnus alpina, Rosmarinus officinalis, Taxus baccata, Thuja occidentalis, Viburnum tinus, Prunus laurocerasus.

The creeping shrubs may be formed into hedges by training on frame-work.

6584. Flowering hedges may be formed of the following deciduous sorts: —

**Rosa** varius species, Cornilla emerus, Daphne mezereum, Hibiscus syriacus, Philadelphus coronarius, Pyrus japonica, Rehmania hispida, Spartium multiflorum.

**Spirea** hypericifolia, Syringa persica, vulgaris, hybridia, or vari, &c.

Subsect. 6. Shrubs whose Flowers or Leaves have Volatile Odors, and diffuse them in the surrounding Air.

6585. Of shrubs whose odors are volatile only a few have this quality in the leaves as well as the flower; these are marked thus: —

**Deidendron**. Aralia most of the species, Betula sibirica, lore, Daphne mezereum, Rosa rubiginosa, Lore, Salix most of the species, but especially S. viminalis, alba, Syringa vulgaris, Climbers. Clematis flammula, Jasminum officinale, Lonicera caprifoliaceae, periclymenum.

**Evergreen**. Lavandula spica, Rosmarinus officinalis.

**Climbers**. Crescentis flammula, Jasminum officinale, Lonicera caprifoliaceae, periclymenum.

Subsect. 7. Shrubs ornamental by their Fruit as well as Flowers.

6586. Ornamental fruit-bearing shrubs are also serviceable as encouraging singing-birds to resort to the shrubbery.

**Deidendron**. Berberis vulgaris, Ligustrum vulgare, Ribes alpinum, syneboti, Rosa spinosissima, et villosa, Sorbus americana, et strangulata, birth, of the species of Vaccinium, Lonicera, Viburnum, Rubus angustifolius, &c.

**Evergreen**. Arbutus unedo, alpina, and uva-ursi, Cornus canadensis, Euonymus spinosissima, Lies, it is profusely covered with odoriferous white flowers early in April, and with dark-purple fruit with a fine bloom, from September to February. It is much cultivated in Japan (1842), where it flowers naturalise the size of a double rose.

**Evergreen**. Arbutus unedo, alpina, and uva-ursi, Cornus canadensis, Euonymus spinosissima, Lies, it is profusely covered with odoriferous white flowers early in April, and with dark-purple fruit with a fine bloom, from September to February. It is much cultivated in Japan (1842), where it flowers naturalise the size of a double rose.

**Climbers**. Clematis flammula, Jasminum officinale, Lonicera caprifoliaceae, periclymenum.

Subsect. 8. Selections of Shrubs for botanical or economical Purposes, parasitic Trees, and Shrubs for a small Shrubbery.

6587. Selections of shrubs may be arranged in innumerable modes, as well as herbaceous plants; as, according to soil, climate, habitation, country, rarity, place in botanical systems, uses in agriculture, or the arts, &c. No gardener can make any selection who does not know by inspection the actual plants, their habits, culture, and history; to him it is needless to repeat the sources to which he may have recourse for forming any classification whatever.

6588. A selection for botanical purposes will necessarily include parasitic plants, of which the only hardy genus is *viscum*. This is propagated in February by sticking the berries, which are viscid when bruised, in a slit like that made in budding, on the smooth bark of the apple, pear, thorn, or almost any tree. If these are not washed away by rain, or otherwise rubbed off, they will germinate in the following summer. To make sure of their not falling off, some bore a hole in the bark and insert the seed; or cut a notch in it, or make a slit: the last seems the best mode, and has been successfully adopted by Professor Thoum in the Paris garden, and extensively by Watts, a nurseryman at Acton, on most sorts of trees.

6589. A selection for economical purposes will necessarily include parasitic plants, of which the only hardy genus is *viscum*. This is propagated in February by sticking the berries, which are viscid when bruised, in a slit like that made in budding, on the smooth bark of the apple, pear, thorn, or almost any tree. If these are not washed away by rain, or otherwise rubbed off, they will germinate in the following summer. To make sure of their not falling off, some bore a hole in the bark and insert the seed; or cut a notch in it, or make a slit: the last seems the best mode, and has been successfully adopted by Professor Thoum in the Paris garden, and extensively by Watts, a nurseryman at Acton, on most sorts of trees.
6589. *A selection of trees and shrubs of great beauty and easy culture, proper for introduction in shrubberies of limited extent:*

*Pyrus japonica,* Robinia *hispida,* Rosa *alba,* Ceanothus *cyanococcus,* Ceanothus *vulgaris,* *Hibiscus syriacus,* *Genista* *dromeda,* *Cupressus* *lusitanica,* *Arbutus* *rubra.*

*Fruits.* *Aegopodium* *podagraria,* *Solanum* *nigrum,* *Fraxinus* *excelsior,* *Sorbus* *nuda.*

*Evergreen trees.* *Ficus* *cymosa,* *Buxus* *suffruticosa,* *Juniperus* *virginiana.*

*Deciduous shrubs.* *Amelanchier* *sambucina,* *Rosa* *rubiginosa,* *Sorbus* *aucuparia,* *Viburnum* *tomentosum,* *Ilex* *aquifolium.*

*Fruit trees.* *Cerasus* *sativa,* *Cerasus* *avium,* *Prunus* *nigra,* *Prunus* *serrulata.*

*Berries.* *Vaccinium* *corymbosum,* *Vaccinium* * Nicola.*

*Chap. XI.*

Frame Exotics.

6590. Frame exotics are such plants as are rather harder than those kept in the greenhouse and of low growth. Some of those enumerated here will also be found among the green-house, and a few among the hardy plants. The frames or pits in which they are kept are never artificially heated, but are well covered with mats or other materials during severe frost. The frames are sometimes attached to the front of the green-house or stove, and thus provide some heat from the front flue, which, when an outside frame is in contemplation, is generally built in the front wall. When this is not the case, they may be advantageously placed on a border sloping to the east, south, or west, under the shelter of a hedge or wall. The pots should be plunged in scoriæ, ashes, sawdust, or any similar non-conductors, and abundance of air, and little water given in the winter time. Few scenes are more interesting in the spring season than a small oblong flower-garden, surrounded by a holly-hedge enriched with many spikes of coral berrys: within the hedge a sloping frame-border all round; on the north side, containing frame exotics; on the west, early-flowering bulbs, as hyacinth, crocus, narcissus, etc.; on the east, choice auriculas; and on the south side (the border facing the north), a collection of alpines. The middle of the garden laid out in beds of florists' flowers. In summer the sashes are applied to various useful purposes, as to ripen fruits against walls, to raise late crops of cucumbers, melons, &c.

The propagation and culture of frame exotics is the same as for green-house plants.
6597. Of green-house plants we shall first arrange some of the more select tribes, and next class the most showy and easily-flowered sorts, under the head of woody, succulent, climbing, herbaceous, bulbs, annuals, and biennials. Each of these subdivisions will be arranged as before as respects time of flowering and color; but considering the limited height which all exotic plants attain in pots, it has been considered unnecessary to attend to size. Such as are trees in their native country will be indicated by the letters tr, and also such as are biennials by the letter b; the most tender, most showy, and those continuing in flower two or three months, as before.

**Sect. I. Select Green-house Plants.**

6598. As select green-house plants we shall consider the geraniums, heaths, and camellias; which three tribes united will supply a green-house with flowers of almost all colors, during every month of the year.

**Subsect. I. Geranium. — Geranium, L. Geranium, Erodium, and Pelargonium, of modern authors. Monadelphia, L. and Gerania, J. Géranier, Fr.; Geranium, Ger.; and Geranio, Ital.**

6599. The *geranie* tribe comprehends numerous species and varieties of herbaceous succulent and shrubby plants, generally of a somewhat succulent nature throughout. They are almost all natives of the Cape of Good Hope, and with the exception of three or four species, have been introduced, or originated here from seed, during the present and latter end of the last century. They are chiefly admired for their flowers, which they produce in abundance from May to September, generally in corymbs from the axil of the leaves, of every shade of red, scarlet, and purple, mixed with white and yellow. The plants are easily cultivated, and by proper pruning, with the aid of gentle forcing in winter, many of the species, as the *P. zonalis*, cuculatum, cordatum, &c. may be kept in flower all the year. The best collection of this family is in the nursery of Messrs. Colville, under the care of the botanist Sweet, whose *Geranie*, now publishing, is the most elegant and complete work of its kind.

6600. **Species and varieties.** Many species and subspecies have been received from the Cape; but the greater number of the admired sorts have been raised in this country from seed; some of these have received systematic appellations, but the greater number have been named by those who raised them after themselves, or their friends, in the manner of florists' flowers. The following table contains some of the old established sorts, arranged according to their habits of growth and time of flowering; the flowers of most sorts are so mixed in regard to color, that it is almost impossible to class them in that respect; most of them are variegated with red, purple, scarlet, and white.

6602. **Propagation.** The ordinary mode of continuing each species, is by cuttings, but almost all the sorts produce ripe seeds in this country, by which they may be multiplied, and also new varieties produced. The seed, if ripe before midsummer, may be sown as soon as gathered, in pots of light rich earth, and placed in a gentle hot-bed and shaded; the plants will soon come up, and if, when they show two proper leaves, they are transplanted singly into pots, and kept under a cold-frame, they will flower the same autumn.

No plant grows more readily by cuttings than the shrubby or succulent species of this family: the cuttings may be taken off at a joint where the wood is beginning to ripen; laid in the shade for an hour or two till the wound heals; and then planted in sandy loam, and placed in a gentle heat. The hardier sorts, as *P. zonalis*, inquinans, &c. will strike in the open air or in any shady situation, without
being covered with a glass. Cuttings of the roots of such sorts, as P. triste, gibbosum, &c., strike readily; a small portion of the root being left above ground. The fibrous-rooted herbaceous sorts, as E. Chamae-
dryoides and glandulosum, may be multiplied by dividing the roots. "From the latter end of March to the middle or end of July," Cushing observes, "cuttings of all the common kinds of geranium may be put in with success. Let the proper temperature, let the cuttings be made, and put in some nice rich loam; plunge the pots to the rim on the bed, and shade them for a day or two, but no longer. Pick off any damping leaves that may appear, water them occasionally, and observe to put them off in due time, by which means they will be stout plants by the end of autumn: the more curious kinds are in general done by cuttings of the thick
fleshy roots, which they produce in abundance: as many of these as can be spared with safety being taken
off carefully from each plant, and a few of the finer fibres attached to them and neatly potted in small pots, leaving the crown of each about one fourth of an inch over the outside, watered and set on a moderate
heat, will, in a few weeks, make excellent plants: one, two, or more stems, which they in general pro-
duce, being left to form the plant." (Exotic Gard. 50.)

6603. Culture. The geranium require a light rich soil; they grow well in equal parts of sandy loam and
well rotted dung; or they will grow in leaf-mould and a little sand, without any thing else. As most
species are rapid growers, the pots require to be examined in spring and autumn, and the roots and top
reduced, or the plant shifted into a larger pot. In general the shrubby sorts should be kept low and
busily by pruning; for when they are allowed to grow tall and straggling, they are very unsightly and
do not flower well. Some of the herbaceous sorts may be considered as frame plants; but the greater number
require the green-house, and some of the very succulent sorts are best grown in the dry-stove. When an
extensive collection of geraniums is kept, it is desirable to devote a house entirely to their culture; in this
the roof should be of a construction to admit as much light as possible, the stage should be kept clean;
and there should be ample means of giving air and heat. Most of the species require rather more heat
during winter than evergreen woody exotics from the same climates; otherwise they are apt to lose their
leaves and rot at the points of the shoots. To prevent this, heat should be given in the daytime and air
admitted, and whenever any leaf begins to decay, it should be removed. The hardier geranium, like other
green-house plants, are generally placed in the open air from May to September; but as the flowers are
much injured by heavy rains and winds, the more delicate sorts, and all those intended to flower in the
best manner, should be kept in the house with abundance of air and night. In warm situations it is
customary in April or May to remove from the P. the P. of the borders of the flower-garden or shrubbery: these have a splendid effect till attacked by frost, when their roots
may be either protected where they stand by abundance of litter and mats, or they may be removed into single
pots, and placed in a dry part of the green-house till the following spring. The Rev. W. Williamson has
found that when young plants are taken up, deprived of their stalks and fibrous roots; the wounds made in doing
this healed by exposure in a dry place; and afterwards the roots deposited in layers in a mass of sand,
placed in a cellar, or otherwise excluded from frost, they will retain their vegetative power through the
winter, and grow vigorously when replanted in the open air in spring. (Hort. Trans., iv. 414.)

6604. Forcing the geranium. The hardier shrubby sorts force well with a very gentle heat, and in this
way may be kept in flower during the winter months till April and May, when they will be succeeded by those
that have been kept in the common green-house temperature.

Subsect. 2. Exotic Heaths. — Erica. L. Octandria Monogynia, L. and Ericææ, J.
Bruyère, Fr.; Heyde Kraut, Ger.; and Macchia, Ital.

6605. The heath family constitute an extensive assemblage of low shrubby evergreen
plants, much valued for the beauty of their flowers, and the blossoming of many of them in the
winter season. Scarcely any exotic heaths were known in Miller’s time, and none of
the Cape species. Almost the whole of these have been introduced to Europe during the
reign of Geo. III., and the greater part by Masson, a collector, who made two
voyages to Africa at that king’s expense.

6606. Species and varieties. Above 300 species have been introduced, some of which, from the difficulty of
propagation, or accidental causes, have been lost; but there are still upwards of 250 sorts, which may be
procured from the nurseries. There are also several varieties which have been raised from seed. The
Hon. W. Herberdt has raised several hybrid heaths, which gives reason (Hort. Trans., iv. 27.) for
thinking that many of the sorts imported from the Cape, and considered as species, are only hybrids pro-
duced by promiscuous impregnation. We have here arranged most of the sorts procurable in the nur-
sery; and, in addition to the time of flowering, height in the open air, and color, designated the form of the
flower, as bell (b), pill or tube shaped (p), open (o), roundish (r), or ventricle (v).

</table>
CAMELLIA.

6608. Propagation. A number of the sorts ripen their seeds in this country, and may be so propagated; but the greater number are struck from cuttings, and some few, as E. massoni, retorta, petiolaris, &c., by layers, which require two years to get to roots. The seeds are often imported from the Cape, and are planted as soon as they are ripe under glass, or in frames placed in a peat and sand, very thinly covered, placed in the shade, and bell-glasses placed over them. The soil must be kept moderately moist by gentle waterings: they will in general come up in six weeks or three months, and it is then advisable to set them in the heathy, or in a frame or pot till autumn, when they may be potted off. Seeds which are saved in this country may be sown as soon as gathered, if they are ripened in September, but after that period it will be better to preserve them till next spring; as the plants produced from them would not be sufficiently advanced to endure the winter. Cushing (Exotic Gard. 17) prefers a Senecio bed for the same purpose, but the plants will stand those which have been raised early in spring, and transplanted in autumn into single pots. Ample directions for striking cuttings will be found in Cushing’s Exotic Gardener, where, that cultivators failed at first by planting them whilst taking care to keep the soil in the heathy. The true

method, he considers, of propagating heaths was first discovered in the Hammonds, with nurseries, and is given in the following abstract of the practice there is from Page’s Prodrumus. "About the month of June, or as soon as the plant has made fresh shoots, cut off the extreme points about an inch long or less, according as the soil is loose or dense, take off the lower leaf or two if it can be done with a sharp penknife, for the least bruise spoils the cutting. Dibble them into a pot, filled with moistened common white house-sand, before they have time to dry; when they are all planted, water the whole to fix the soil; do not allow them to be in the pot or place them in the shade on a spent hot-bed, keeping them close till rooted, which will, with the free sorts, take place in about two months; when rooted, which is known by their shooting, take off the small glass, for about a week, at night, previous to its total removal. They will be fit to pot off in March the ensuing year." 6609. Henderson of Woodhall’s mode of striking ericas is as follows:"—The month of July is a good time for this operation; but most of the propagating sorts the cuttings must not be taken off till the young wood be firm. Cuttings of ericas may be put in at any time when the wood is of good quality, and the ericas are in the flower stage. Pot plants about three quarters of an inch long, pulling them off downwards; strip off the leaves nearly half the length of the cuttings; place the cutting on the nail of the thumb, and, with a sharp knife, at right angles with the shoot, cut off the small end close to the joint, or place where it was pulled off. Having done this, plant them into a pot filled with small peat or river sand, giving them a good watering to settle the sand about them. Set them on a shelf where they are a little shaded; cover them with glasses, and notice to keep the sand always moist. Some of these sorts will be well rooted in three months, and others will require longer time. Henderson says, "Erica Caled., in September, as is the old method of raising them, except that flowers are not then expected - When the pots have grown in good health, transplant to open ground after four years without shifting, and flower well. I have plants of erica retorta here, in pots seven inches in diameter, which are 6 or 7 years old, being eighteen inches across, and fourteen inches high above the pot; erica infundibuliflora, two and a half feet in diameter, and two feet nine inches high; erica pilosa, betwixt five and six feet high, and these have been seven inches in diameter: these have not been shifted for five years; they are in a high health, and covered with strong fine flowers from the month of the pot to the top of the plant." (Caled. Mem. iii. 227.)

6610. Culture. "A prejudice," Page observes, "having spread that the culture of these plants is difficult, one of the greatest ornaments of the green-house has hence, of late, been neglected; although the method of culture is as easy, and nearly as certain, as that of the geranium, but requiring a little more diligence in the execution." The soil for all the species is earth peat mixed with from one sixth to one fourth of fine white sand. The pots should be well drained and rather small; but large, in proportion to the size of the plants. Heaths thrive best in a house by themselves, and placed as close to the glass as possible, without risk from frosts: they do not require so much heat as most green-house plants, but abundance of air, and, above all, great regularity as to water, so as to preserve, as much as possible, an equable and moderate degree of soil moist, and in this the mass of successive days of the season is most likely to be of consequence. They must be carefully protected from cold, and from the heaviest frost. In the open ground they are usually grown on the sides of large towns. In the best situations and under the best management, many of the species are short-lived, and therefore require to be frequently renewed by cuttings or seed.

6611. The ericas are not subject to insects. Henderson says "I have never found any insect on them except the caterpillar of a small moth, which the bees are very much addicted to; but I have observed the flies by dipping the plant in an infusion of tobacco. The ericas, I find, do not agree well with being smoked with tobacco-paper in the usual way." (ib. iii. 227.)

6612. Of the camellia genus there are four species introduced: the C. bohea, viridis, and sasanqua, are the plants whose leaves furnish the tea imported from China; C. japonica, introduced in 1759, is an ornamental evergreen shrub, which grows to the size of a low tree in China, with dark-green ovate leaves, on short petioles, and flowers red, white, striped, and variegated, and single, semi-double, and double, without fragrance, but of great splendor in flower, and peculiarly valuable, as appearing in December, January, and February.

6613. Varieties. These are —

| White | buff, double, variegated, and spotted-leaved. |
|——|——|
| Pink | buff, long-leaved, striped-leaved, withered, &c. |
| Yellow | orange-leaved, lady’s ♀, green-leaved, &c. |
| Green | procured from seed, which are not cotyledon, six-angled, and warath. |
| Blue | striped, double, variegated, and spotted-leaved. |

There are above half a dozen other sorts, which have not come under my observation, but which are named, and many hybrids have not yet come into flower.

6614. Propagation. The single red camellia is propagated by cuttings, layers, and seeds, for stocks; and on these the other sorts are generally inbred, and sometimes budded or grafted. The cuttings are formed of young shoots, and are the succeeding spring, which are taken in August cuttings of from 6 to 8 inches long. Place them in joint or bud, two or three of the lower leaves only taken off, and the cuttings then planted and made firm with a small dibber, in pans of sand or loam, or, by some cultivators, sand and peat, or sand alone. The pans are kept close, and are covered with cold frames, and without glass, but shaded during powerful sunshine; and on the following spring such as are struck will begin to push, when they are to be placed in a hot-bed. In September or October following, the rooted plants will be fit to pot off; and in the second or third spring they may be used as stocks. Henderson puts in camellia-cuttings at any time of the year, excepting when they are young wood. He puts fifty cuttings in a pot of small eight inches in diameter, sets them in a cool place in the back of a vinry or peach-house for a month or six weeks, and then plunes

Book II. CAMELLIA. 909
to them in the brink of a hot-bed where there is a little bottom heat. A speedy mode of obtaining stocks is by planting stolons in a pit devoted to that purpose, and lagging these in autumn, when the flowers are fully open, most of the layers may be transferred to the flower bed when the blossoms are just closed, and used as stocks in the following spring. Inarching or grafting is performed early in spring, when the plants begin to grow; the chief care requisite is to place and fix the pot containing the stock, as that it may not be disturbed during the connection of the scion with the parent plant. The scion should, if possible, be cut with a flat mouth (201.), but any crack in the bark (201.) is generally used, as in the case of orange-trees (591.); but the operation of tonguing is generally omitted, as weakening the stock, and unnecessary, with a view to prevent the scion from being blown off by winds. A few seeds are sometimes stripped from the semi-ripe fruits of the sea-camellias, and from these two years to come up, but make the best stocks of any. The tea-camel-

lias are generally propagated by layers, but will also succeed by cuttings.

663. Soil. Some cultivators grow the camellias chiefly in peat; but Messrs. Lodgdone, who have the most number of this kind of used loam, and freely pruned it, and are grown in a similar soil in the Hammersmith nursery. Of late, Messrs. Lodgdone find light loam alone to answer as well or better. In the Count de Vande's garden, at Bayswater, rotten dung is mixed with loam and peat, and the surface of the beds is strewn with fresh cow-dung. Starry moss, and to a less inequity of surface, or thickness of material so operates, must be concentrated on the sun's rays, as to concentrate them, and burn or produce blotches on the leaves of the plants. Every cultivator must have observed that lethary shining leaves, like those of the orange, myrtle, &c., are more or less obnoxious to this position. The leaves of the plants, but the leafy portions of the stems, are represented as requiring a roof which will not admit much light; others, the use of green glass; of an opaque roof, with glass in front only; or, of a house facing the north. Our opinion is, that a light house facing the south, or, better still, glass on all sides, is essential to the perfect growth of the plants. Care may be avoided, or at least rendered of no consequence, by using the best glass, and placing the plants as near it as possible.

667. To grow the camellia to a high degree of perfection, considerable care is requisite. The roots are very apt to get matted in the pot, and by the space of time that they occupy the top of the bulb becomes firm. Hence frequent attention should be had, to see that the water poured on the pots, moistens all the earth, and does not escape by the sides of the pot, moistening only the web of the same. The cause renders examining the roots, and shifting or reducing and replanting them, a necessary measure, at least once a year. When the plants are grown in the full sun, and are consequently quite dry, and watered, and also a degree of heat somewhat more than is usually given to green-house plants. If this heat is not given in November and December, the plants will not expand their blossoms freely; and if both water and heat are not regularly applied after the flowering season, the plants, that should be trained with single stems to rods, and pruned so as to make them throw out side branches from every part of the stem: to encourage these, the plants should not be set close together on the stage. In April they may either be set out of doors on a stratum of scorch, or on a pavement, in a sheltered but open situation, or the glass roof may be used. The double and single red camellias will endure the open air, when trained against a south wall, and protected by mats in winter; and there can be no doubt that in these and other species will be more perfectly insured to our climate. “Goodwood,” is one of the following accounts of a mode of treating the camellia. “The best time for a regular shifting of the camellias is the month of February or beginning of March. After shifting all those that require it, put them into the peach-house or vinery, where there is a little heat; if there be no peach-house, vinery, nor garden, apply to them in the green-house; you will not produce to form hands of flower-buds, that were contained in flower-buds, if you remove the green-house, the flowers will be a fond of being shaded during strong sunshine. In three or four weeks, after a few more of the camellias may be brought from the vinery or peach-house, and put into a cooler situation. This may be repeated three or four times, which will make as many different successions of flowering. Those that are wanted to come into flower early, may remain in the warm house till they are beginning to flower, when they should be taken to a cold place, say behind the stage of the green-house; for the camellia are fond of being shaded during strong sunshine. In three or four weeks, after a few more of the camellias may be brought from the vinery or peach-house, and put into a cooler situation. This may be repeated three or four times, which will make as many different successions of flowering. Those that are wanted to come into flower early, may remain in the warm house till they are beginning to flower, when they should be taken to a cold place, say behind the stage of the green-house; for the camellia are fond of being shaded during strong sunshine. of colors. The plant is large and handsome, being eight feet six inches high, and six feet nine inches wide. There is another plant here, twelve feet high, having upon it all the sorts I possess. They were only grafted last summer, and a number of the sorts are showing flowers; grafts of all of them have taken and are growing well. The plant is growing in a box sixteen inches over by sixteen inches deep.” (Cited. Mem. iii. 316.)

SUBSEC. 4. Various Genera which may be considered as select Green-house Plants, showy, fragrant, and of easy culture.

6619. Of other select green-house plants, the first we shall mention is the citrus tribe, already treated of as fruit-trees (4879.) ; the beauty and fragrance of which need no encomium. They merit a house by themselves, though they will thrive perfectly in the same climate as the camellia. The myrtle comes next in order: nerium is a well known genus, whose flowers are of great beauty and long duration; fuchsia is universally admired; jasminum, gardenia, and daphne, have flowers of great fragrance; heliotropium is remarkable as smelling like new hay; various species and varieties of rosa indica and semperflorens are both beautiful and odoriferous, and flower throughout the winter. Among the new genera from the Cape and Botany Bay, acacia, mimosa, eucalyptus, melaleuca, metrosidors, and the proteaceae, are admired for being prolific in showy flowers, which, for the most part, appear early in spring, and being chiefly evergreens and large-growing hardy plants. Diosma, gnidia, and struthiola, are admired for their minute foliage and elegant flowers; those of xeranthemum are prized for their durability. Bignonia, coeca, dolichos, jasminum, lonicera, and passiflora, are admired climbers; of passiflora some beautiful hybrids have been originated by Milne of the Fulham nursery. (Hort. Trans. iv. 258. and v. 70.) Mesembryanthemum, cactus, and yucca, are curious and beautiful succulents; amaryllis, cyclamen, iris, ixia, and gladiola, lachenalia, babiana, ferraria, and oxalis, are beautiful bulbous-rooted plants; and calla, celsia, cineraria, lobelia, tropæolum, and jacobea, select herbaceous sorts.

6620. The principal species of these genera will be found arranged in the following sections, with their colors, and other particulars, added to each. They are of easy culture, and, with the genera of the preceding subsections, may be considered as affording the best choice for a small, showy, odoriferous, evergreen, and ever-flowering collection.

6629. Propagation. The method universally applicable is that by cuttings; but a few sorts, which are very difficult to strike, are sometimes layered, grafted, or inarched, and a number are raised from seeds.

6623. Many green-house plants bring their seeds to perfection in this country; at whatever time these ripen, unless before midsummer, it is best to keep them till the following February. Sown at that season they soon vegetate, and make strong plants before winter. The pots should be well drained, filled with mould suitable to the species to be sown, and the surface covered with mould of the finest quality, as a bed for the seeds. Several kinds may be sown in a pot, where the quantity of seed is not great, or its quality doubtful; cover with the same fine mould, according to the size of the seeds, and then give a
gentile watering with the finest rose-water potting. They may now be set in the most dry airy part of the propagation-house, where they can be regularly attended, as to watering and weeding.

Watering: Usually watering they will require at least once a day, in a greater or less degree; for if they are not kept properly moist, they will not by any means grow. If at all the other extreme is to be studiously avoided. The weeds should be regularly pulled out before they attain any size; else, besides their tops smothering the young seedlings which may have started, the roots, in growing towards, not only damage them, but send forth from the young seedlings that may be perhaps on the point of bursting their embryo. As the spring advances, it will be necessary to lay a few sheets of strong paper over the pots, for two or three hours in the middle of the day, if the weather happens to be clear, and the sun acts powerfully on them; particularly those in which the finer seeds are sown, in order to prevent them from getting over-ripe; or if the most favourable circumstances combine, it is liable to form a mossy crust, which might be particularly injurious, by preventing the young seedling uating itself into the light, from penetrating through it with that ease which is requisite. In this managed until the middle of the season the larger kinds of seed may be removed to a shadier border, where the pots can be plunged nearly up to the rim in lime or sand; which will greatly assist in a proper moist state: here, all the care they will require is to be kept free from weeds, and regularly watered, morning and evening, if requisite: but never when the young seedlings show signs of becoming chilled, or if the atmosphere is damp, it will be necessary to have a careful eye daily for slugs, worms, &c. Should there be any fine light-covered seeds, such as heaths, &c. they must be set in such a manner, that they may be covered with a common hot-bed, or at least with the same, so that in any event of snow or heavy showers, which might otherwise wash the seeds out of the pots, they might be occasionally covered with some straw or moss, and this, though for the prevention of frost, violence; yet they may be exposed to gentle rains at times, but never long together, lest they become over wet, which would soon perish them in this tender state. They will likewise require to be shaded with a mat in clear weather, or even a double mat, in the very hottest season.

6625. Potting off. Early in July, many of them will be growing pretty fast, and will require to be potted off into separate pots; as it is much preferable to do this while they are young and small, before their leaves become maturing upwards; besides, that they have a considerable portion of the growing season before them to establish themselves, in the pursuit of their career. In performing this work, care should be taken to match the pot to the size of the plant, and nature of the species to be potted; as over-potting these small seedlings might be of the worst consequence. The largest-sized potting should, as strongly, No. 1, &c. but the heaths, and such like very small articles, a still less size, known by the name of thimble pots, are to be preferred.

Being provided with a quantity of these, and the different sorts of mould properly prepared, that may be requisite for the kinds to be proceeded to part the plants, in doing which, let the nicest care be taken to preserve as much roots and earth as possible, that at the same time the plants may be of the same strength, and be neatly potted in the proper mould, which must be gently pressed to the roots, that they may the sooner incorporate themselves with it. In this manner, as many as may be thought sufficient for the present purpose, at the same time allowing a few for mishances. They may then be well watered, in the manner already directed for seedlings, and set in a cool frame, on coal ashes well rolled, or any other hard substance that will prevent the worms getting so freely into them, as they otherwise would. The lights must be kept constantly on, and closed, for a few days, more or less as circumstances may require; and it will then be necessary, as of the/std. to guide them, to allow the air to be admitted at this time, so as not to be too soon accustom them, but to prevent this, the lights may be taken off at night, if fine, having them on, and shading in the day, until by degrees the plants are so hardened as to be able to withstand the full power of the sun; thus, in the space of a few days, they will be fit for the open air, and the other plants. This business should not be undertaken later than the middle of August, for if executed at a more advanced season, the plants will not have necessary to examine with care whatever pots have not by that time shown any signs of vegetation, and those which are found alive must be saved, and treated in the same manner as fresh-sonw seeds.

6626. The pots set in the house will require nearly the same treatment, viz. to be kept perfectly clear from weeds, and regularly watered. Water should now be given in the morning only, as any damp it may occasion will have time sufficient to evaporate in the course of the ensuing day; whereas, if given in the evening, the stillness of the atmosphere, the nearness of the house to the sun at first, and however, in a little time, the lights may be taken off at night, if fine, having them on, and shading in the day, until by degrees the plants are so hardened as to be able to withstand the full power of the sun; thus, in the space of a few days, they will be fit for the open air, and the other plants. This business should not be undertaken later than the middle of August, for if executed at a more advanced season, the plants will not have necessary to examine with care whatever pots have not by that time shown any signs of vegetation, and those which are found alive must be saved, and treated in the same manner as fresh-sonw seeds.

6627. By cuttings. This mode of propagation may be commenced about the middle or end of January. As young shoots in a growing state generally strike most freely, where these are wanting on particular specimens, the plants may be forced for a few weeks in the stove, or in any of the pits in the reserve flower-garden, to produce them. All the soft-wooded, tender, pithy kinds, such as indigos, eodoralia, polygala, hoctonnia, ehironia, &c., as well as some of the more curious geranum, may require this treatment. By the end of February, the heat will have produced shoots of from two to four inches in length, and from that to any time in March, proceed to cut and dress them neatly with a sharp penknife, taking off all the leaves as close to the stem as possible without wounding it, except a few at the top, to be left for the free respiration of the cutting: this observation should be particularly attended to in making cuttings of evergreens in general, whether hardy or tender: let them be cut off at bottom with a clean horizontal cut, at a joint or bud, and immediately inserted in their proper pots. To have these properly prepared is a very necessary part of the business; being well drained, they should be rather more than half filled with the mould or compost best suited to the nature of the plant, and afterwards filled with good loam or sand, whichever may be
thought more advisable to insert the cutting in: if sand is used, it should be previously well watered, otherwise it cannot be sufficiently tightened to the base of the cutting; a most essential point to be observed; however, it should have time to be well drained off from the pot before the cuttings are put in; as they, being so tender, are extremely liable to damp at this season; than which nothing is more injurious. The loam will, in general, be found sufficiently moist of itself; and should it be of a fine, sandy nature, so much the better; but if not, a third or fourth part of fine sand should be added, and well mixed previous to its being used.

6629. Being properly planted, let them be covered immediately with the proper glass, well fitted, and pressed moderately on the mould, so as perfectly to exclude the air. They should then be plunged in the front of the propogation-house, or in a hotbed; or otherwise in a hothouse or frame; the inside of the glass should be regularly wiped with a dry cloth every morning; and any of them that happen to damp, carefully taken away before they contaminate the rest. If the sun happens to be unclouded, the glass should be shaded for about half an hour in the afternoon, or otherwise, the buds may be injured; no other kind is to be left on too late in the afternoon, as the cuttings being so soft and tender, are extremely susceptible of injury by over-shading. In the space of ten days or a fortnight, some of the free-rooting kinds will be making efforts of growth; as soon as this is noticed, it will be necessary to give them a little air, by taking the glass off every evening, when the sun is quite reeded from them, and putting them on again early the following morning; until they are by that means hardened, so as to be able to bear the full power of the sun without the glass, when it is to be entirely discontinued. If any of them should drop their heads when this operation is first performed, it is proper to refrain from moving the glasses until every head shows a strong healthy appearance, that there will stain as to be entirely done away while there remains any of them under glasses. In this manner the business is to be followed at different intervals, according as the cuttings are ready during the months of March and April.

6630. Potting off. Some of the first put in spring cuttings will, in May or June, require to be parted and potted separately in small pots; in performing which, be careful to avoid breaking the roots, using them in the same manner as for seedlings, and directed to be set in the propagation-house for a few days, and shaded until they have established themselves in the fresh mould: as soon as they have taken to grow freely, let them be removed to a frame; but observe not to expose them to the open air entirely at first, as it might do them a material injury, on account of which, the lights over them should be kept closer than usual for a few days. About the middle of June, any cuttings of the tenderer green-house cuttings that have been left in the propagation-house since spring, should be plunged under the cap-glasses along with the others: where the whole must be carefully attended to every morning, to pick off dried, dry-looking cuttings, and water all as advisable, when the leaves are very large, to let the glasses stand off about a quarter or half an hour, to dry the surface a little, except the sun happens to be very clear, and shining direct on them. It has been already remarked, that there are many kinds which do better without the small glasses; such as the strong-growing, spongy, and succulent kinds; also, the daphne, laurelias, and similar kinds. The camellia, liriope, and many others, have their leaves scorched by the glasses collecting the rays of the sun. Any time during the months of June or July, cuttings of these sorts may be made with success; as by that time the young shoots will be sufficiently firm for that purpose, and will strike freely in good loam: but camellias, and such like sorts, should not be cut till their growth has been halved; or after they have lost the leaves which they are, when taken too young, particularly subject to rottenness and damp. In July, and August, there will be many of the earlier cuttings growing; they should have their glasses taken off, as before directed, and be planted in a few days in a more exposed situation, to harden them by degrees, in which they must be shaded from the mid-day sun, but freely exposed to the air at night.

6631. Parling and potting should also be occasionally performed on such as are ready for that operation; when, if any of them happen to be more backward than others in the same pot, and not rooted, let them be parted and potted separately; the cuttings, and the set for seedlings, where they must be kept close and shaded, except in mild weather, until they are by degrees inured to the free air.

6632. Removing to the propagation-house. At the season in which it is judged advisable to house the propagated collection of green-house plants, it will be also requisite to have the cuttings removed to the propagation-house, to be cleaned, sorted, and regulated, according to their different kinds and stages of growth. The common sorts will be do to set in any part of the house where they will have free air about them, that they can be continually taken advantage of, and conveniently disposed of. As many as more curious kinds should be set in a dry airy part, where they can be carefully attended, to prevent their getting over dry or dirty, and also to take the glasses occasionally off those that may be growing. All the back weeds, and others, or any other hard-wooled kinds, such as are most of the Botany Bay plants, &c. that take a long time to strike in the cloche, and that stand the cloche, and drier situations of the hot-house, where they must be watered and cleaned, like the others, throughout the win-
6634. General culture of woody green-house plants. We shall commence with the shifting season, which generally takes place about the end of May, and trace, from Cush- ing, an outline for their general culture and management throughout the year. Green-
house plants, this author observes, for the most part require a considerable share of
pot-room, as many of them are very free growers; but still great caution is necessary to
avoid over-potting the tenderer weak-growing kinds. When shifted, let them be neatly
tied up, if requisite, and well watered. Any dead or ill grown parts can now be, with
propriety, cut away, so as to give the heads a regular neat appearance. In bright sun-
shine it may be also necessary to shade them for a few days from the influence of the
sun and winds, until they are perfectly established in the fresh mould.

6635. Placing in the open air. By the middle of June, it will be time to think of preparing the
out-of-doors for the plants. The season of the plants should only be the same as the
winter quarters, where, if the green-house is built on a proper principle, they can still have the
free air, and at the same time be in a situation to be protected when necessity requires. They
should, at all events, be removed in the earlier part of September. Therefore, about a fortnight before that
time, they should be regularly examined, and any roots that have extended themselves through the holes
at the bottom of the pots, cleanly cut away: this tends to stop the too luxuriant growth, and being exe-
cuted at a proper period, before their final removal, they have time to recover themselves from the partial
corruption, if defective. If conducted by it, it will completely free them of any disease and
moving them into the house; the transition from the cool bottom on which they stood, to the dry boards
of the green-house stage, being so materially different. Whatever may be the mode of arrangement
adopted (6235), the plants must not be set too close when first put in, as it would occasion most of their ten-
ders to perish. Should they, in the mean time, happen to have been built on a close construction, be by any means taken in when their leaves are wet.

6637. When they are all housed, and dirt of every description taken away, let as much free air be given as possible. The doors are left open and even at night, so as to give the plants a moderately mild, and free from
any appearance of frost. Frosts, at this early season, are seldom so severe as to injure any green-house
plants that were not immediately exposed to its perpendicular effect; therefore the front windows may be
kept open continually, unless there is a prospect of its being particularly severe, or accompanied with cold
blowing, winds, in which case it will be necessary to hang them pretty close, that air is too sparingly
admitted at this season, when many of the plants have not yet finished their summer’s growth, it will in-
variably cause them to produce weak and tender shoots, which will be extremely liable to damp off at a much
earlier period than at the beginning of the season, and injure the appearance of the external air; and besides, it will tend to give them a more general tender habit, and render them less
able to resist the winter colds than they otherwise would. Hence it is evident, that they cannot receive
too much air, whenever the state of the external air will admit of it, by being free from any appearance of frost,
as it will be so much to their advantage to be thus hardened before the winter assumes its greatest severity.

6638. Water should also be plentifully administered when they are first taken into the house, as the dry
boards on which they now stand, as well as the elevated situation and free circulating air, occasions them
to require more than when they stood on the moister earth; however, by no means go to the extreme, giving
it only when evidently necessary.

6639. As the close foggy weather advances, water must be given more sparingly, else it will conspire with
the cold to injure the plants, which will then be the dangerous part, and very uneasily
leaves. These, and dead flowers, should be picked off as soon as they are observable, otherwise they will make
a very disagreeable appearance.

6640. The months of November and December seem to be more noxious to the health of plants than any other
in the year, by reason of their being full of young sappy leaves, and the remains of many of the autumn
flowers still on them, when the weather (which at this time generally becomes close and chilly,) renders
it necessary to keep the house shut and warm; this occasions so most pernicious damp to exhale from every
part of the plants, which then from the heat and moisture exhaled on the leaves, to their injury, particularly
the younger parts, such as were the produce of the preceding summer. If this kind of weather continues for any considerable time, it will be advisable to give a little fire-heat, to help in drying up these baneful exhalations, and also as much air as can be safely ad-
mired by the doors and front windows, more especially when fire is added, otherwise the heat of the flues
will, instead of expelling the contaminated air, rather occasion it to exhale more freely, and be of worse
consequences. At this season also, the plants should be regularly examined to clear them of all dirt, and
also to scrape off any moss, etc., that may have grown on the surface of the mould, and to renew it with a little fresh loam; this contributes much to their good appearance, if neatly executed.

It is a very little difficulty to compare the appearance of green-house plants in this climate; in fact, the less it is found necessary to use the better. Except in the case of damp, as before mentioned, it need not be used till the frost be so severe as to lower the thermometer several degrees below zero, and then only to raise it again to that point. If this can be done without the assistance of fire, so much the better; for which purpose, bass mats may be used along the lower parts of the house, where they can be conveniently fastened: these will be of infinite service, even when fire is used, as less of that element will suffice; but they should be always taken off in the day to admit the light, unless the temperature be lower. It may also be necessary to remove some of the particles from the mould in the pots is kept at this season the better, as it will be less liable to attract the frost; therefore, water must be used very sparingly, and only to such as are in actual want of it. Sometimes, in the depth of winter, there is a succession of very clear weather for several days together, when it may be useful to fasten the coldest frame in the house, and to give a flower, which fires have been absolutely necessary; in this case, it will be requisite to give all the air possible in the day, (unless strong hard winds, or other occasional prece- vents, happen to prevail,) observing to shut the windows up close early in the afternoon, so as to include part of the coldness within the house. Such weather will of course be held in an inverted position, with the hand placed so as to prevent the mould falling out; in this manner, plunge the plant into the water, and while it is wet, holding it in the same position, let another apply the above preparation with a powder-puff, or some such machine, in such a manner, that no water, in the proper seasons, that is, when the air is perfectly calm, and if close foggy weather, so much the better; every aperture should also be stopped, so as to exclude the external air as much as possible.

Towards the end of winter, the plants should be regularly examined, and cleaned from any filth they may have acquired during that dreary season; such as moss on the surface of the pots, and leaves that have dropped thereon; also any plants that may have grown into a loose habit should be tied up. The platforms or stages should be clean brushed, whilst the plants are removed, and any worms that may have been lodged, by turning them upside down in shifting the root of the air, without breaking the root of the plant, at the bottom or sides of which they are generally to be found. It is easily known when they are in the pots, by their casts on the surface. Indeed, this is a thing that should be attended to at every season of the year, as they are to be observed more or less at all times, and considerably dis- gusted the appearance of the plant, when suffered to persevere.

As the spring advances, it will be found necessary and convenient to admit a more free circulation of fresh air, and on account of the increasing drought and heat of the season, water must be given more plentifully than at night or in the early morning, as it is then open, as the weather is in general so very changeable at this season, that it frequently happens, although the evening may appear mild and serene, the morning usters in with a severe frost, which, if admitted to the plants, would materially injure them; and perhaps at once render all the winter's care and attention abortive. The climate of the middle of May, the weather seldom becomes in any degree settled; but at that season we may venture to expose the plants both day and night to all the vicissitudes of the weather, should it continue in any degree moderate. Being thus treated, they will require a considerable increase of water, which may now be copiously given to them, particularly the more free-growing kinds; but let the following be observed, as a general maxim not to be departed from; that it is necessary to the health of plants, especially the tenderer species, to be permitted to become moderately dry before they are again watered; because, when kept in a continual wet state, the mould becomes entirely destitute of that active quality so indispensable to the plant, on the contrary, will assume a most unhealthy appearance, which may perhaps not attribute to the proper cause.

Treatment of green-house plants in a conservatory. This should resemble the treatment of plants in pots, as far as the difference of circumstances will permit. The plants in the conservatory cannot be set out in the open garden; but the roof may be removed to produce the same effect, and should be done about the same time. Instead of shifting, the soil can be refreshed by manure and top-dressings, or it may be entirely renewed; and pruning, training, and attention to cleanliness and neatness are alike applicable to both modes of culture. When the green-house plants are housed, the lights or roof of the conservatory should be replaced. The plants, in the meantime, will require as much air as it is possible to admit on all fine days, and in case rain prevents the letting down of the roof-lights, the front ones, if any, should be as open as possible. This is to prevent the plants being drawn into long naked stems, and weak branches, which, from their free habit of growth, they inevitably otherwise would be. As the cool of winter increases, which it naturally will do in the months of October, November, and December, a proportionate decrease must be observed in giving either air or water;
and, if necessary, add a little fire-heat, and mats along those parts of the glass nearest the plants, in such manner as to prevent the frost or piercing winds from injuring them. The conservatory, in these particulars, requires to be managed in the same manner as directed for the green-house. As few objects are more desirable than to preserve the gay appearance of the plants, it will be requisite to pay constant attention to the removal of decayed leaves and weeds of every description; also to tie up or cut short any loose straggling branches that happen to show themselves, to remove those pots which may have been plunged or set on the pit when out of flower, and, if convenient, to have their places supplied with others in a fresher state.

649. During November, December, January, and February, the moisture of the atmosphere in such departments, where there is a great body of damp mould, will occasion several species of the bryum, and other mosses, particularly the fungi, to vegetate; particularly as the mould has had time to settle, and the surface to become of a close firm texture, which would give the house a very unclean appearance. It must be remedied by frequently stirring with a small fork the whole of the pit, to the depth of two or three inches, and raking it over smoothly with a neat-toothed rake; which, as well as the fork, should be particularly adapted to this purpose, by being furnished with short handles; so as to enable the operator to use them with freedom under the plants, by which means many branches and flowers will escape being broken off, which cannot be well avoided when awkward tools are allowed to be used for this purpose. As soon as raked, let some fine-sifted fresh loam be thinly scattered over the surface, and it will tend to give it a more agreeable appearance; besides, being dry, it will serve to imbibe a good quantity of the superabundant moisture.

650. As the spring advances, they will require considerable attention to keep them in proper order, on account of their great increase of growth, more particularly the climbing plants, trained against the walls or trellis-work; these should be daily attended to, and trained in their proper places; directing their course to those parts of the house which, from their nakedness, appear to want them most: also these species of plants being remarkably free growers in general, it will be requisite to thin them, by cutting away any unsightly parts, and those branches most destitute of flowers; by which means there will be sufficient room for the young vigorous growth, and these should be trained in regularly as they advance, otherwise they will attach themselves to the first object they meet, and render it difficult to dress them neatly afterwards.

651. Sings, snails, and other vermin, are very fond of harboring among the leaves of these plants, when permitted to grow crowded; also under any low bushy plants in the pit, whence they make their nightly excursions, to the great injury of the foliage in general, if not perceptibly detected. The drought and warmth increasing with the year, will render it convenient to admit more air, and an increase of water; two very essential points, that should never be neglected.

652. In summer, the lights having been removed, as before directed, the plants should have any necessary pruning, and be all regularly trained, and to secure them against the fire action of the wind; they will, if the weather happens to be dry, which is most frequently the case at this season, require an abundant supply of water, particularly the strong free-growing sorts, on account of being thus exposed to the open air. The cause for this thus taking place, is that the plants may have the benefit of the warm invigorating showers of that season, and the action of the perpendicular air, which will be a great means of their acquiring that strong, healthy, robust growth, so much wished for; indeed, where it is not practised, the plants seldom fail of being drawn into the opposite unseemly extreme. In two or three years from the first planting, many of them will be grown to as large a size as the house will admit. The knife must be then freely used among such, to keep them within bounds, and prevent their injuring each other, which they inevitably would, if permitted to grow too close together. However, in performing this, one must be very careful lest they disfigure the general appearance of the plant, cutting away only the rude and overgrown parts, which should be taken clean off, without leaving any of the stumps behind. The younger parts which are suffered to remain should then be tied neatly up, so as to form a handsome mounding-sized bush. It will also be necessary to observe whether any have outgrown their neighbors in the front rows; these may conveniently be moved into more backward situations, and their places supplied with other new varieties, if to be had. This work may be done with safety any time in spring or autumn, when the weather happens to be a little dull; it will be advisable, however, to cut off a few of the most luxuriant shoots, and to run a spade or large trowel down, around the roots, so as to form a little mound, and transplant them, which also operates in training back, and bringing up the free growth of the plant. It should be taken up with a good ball of roots and earth, and well watered as soon as replanted; it may also be found requisite to shade such as are thus removed lightly for a few days, if the weather happens to be very clear. (Climbing.)

6653. The propagation and culture of this tribe is the same as for woody plants. The situation proper for planting climbers and creepers has already been considered. (6204.) To cultivate them to perfection, a house should be entirely devoted to them, in which they should be planted in prepared soil, and trained on latticework, or an arbor, or on single rods running from the front or sides of the house to the back or centre; if sufficiently distant, the glass to show the beauty of the flowers and foliage to the spectator.

6655. Propagation. With succulents this is remarkably easy, as cuttings and suckers, where they can be procured, seldom fail to put out roots; however, some sorts of aloe, crassula, &c. do not readily produce shoots of any sort by which they may be multiplied. When the leaves are taken off cuttings or suckers, the latter should be laid on a dry airy place, till the wounds heal; they may then be planted in the proper soil, one in each of the smallest-sized pots, and being kept a few weeks in a dry heat, and shaded from bright sunshine, they will seldom fail to grow. In raising succulents from seeds, proceed as directed for the seeds of woody plants; but observe to be more sparing of water after the plants come up. 

6656. Culture. A sandy loam is the soil universally allowed as the most proper for these plants; not over finely sifted, in order to let the water pass the more rapidly through it; and for the more succulent and dwarf sorts as stapelia, cactus, &c. about an eighth part of old lime-rubbish may be added. Succul- ents do not associate well with any other description of plants; therefore, when they are extensively cultivated, there should be a house or houses on pur- pose for them. One house would be required for the more hardy sorts included in this section, and another for the dry-stove succulents, given in a succeeding table. They require very little watering, and never over the top during the winter months; in summer, if the pots be well drained, they will bear more water, especially when in flower. The pots in which they are placed should be smaller in proportion than for other plants, as they grow slowly, evaporate little, and apparently derive great part of their sustenance from the air. They need not be shifted oftener than once in two or three years; but the surface earth should be taken off, and fresh compost added every year. They do not require to be set out in the open garden during summer; but as much air as possible should be admitted to them, and the roof of the house should be open at that season, night and day, excepting during heavy rains. "The greatest injury," Page observes, "which these plants have to be guarded against, is damps in winter; therefore they should be frequently loosened, and all decayed parts removed, particularly from those which are stemless, and when the leaves touch the earth." He adds, "few of these plants, either those of the green-house or hot- house, are cultivated in general, but merely to fill up the by-shelves and odd corners of the exotic houses; but if a proper attention was paid to them, and their cultivation better known from a study of their characters, we have no doubt but they might be rendered as ornamental and interesting as those now considered the most select. Most of the forms and growths of these plants are truly curious; and many of their flowers the greatest beauty and brilliancy. Since the days of Dillenius and the late James Lee, these plants have had few admirers; but the present Emperor of Germany, the Prince of Salerno, the Vicc-King of Lombardy, and our countrymen Haworth and Anderson, the latter the able curator of Chelsea Botanic Garden, are endeavoring to bring them again into that notice which they so eminently deserve." (Prodr. 190.)

Mammillaria lanosa and Senecio hohenwartii are plants out by Mowbray, in a pit along the front wall of a hot-house. Mammillaria lanosa, the soil he uses is rich garden-mould and fresh loam: "the sorts are M. cladens, aurantium, perfori- dolis, deltoideus, barbatum, and other species of different habits; the strong-growing kinds are put to- wards the back, and the dwarf sorts in front. They grow vigorously, and flow; nothing can surpass the brilliancy of their blossoms in a bright summer's day, and many of them continue flowering all winter. All the culture they require is thinning and protec- tion by mats over the glass in severe weather. In summer the ashes are taken off, and the soil may be covered with stones like rock-work." (Hort. Trans. v. 234.)
6659. Propagation and culture. After the ample directions on the subject of propagating and culti-
vating bulbs, already given (6561.), very little can require to be added here. A mode of propagating such as rarely produce offsets may be mentioned: it applies only to tunicate bulbs, which, if cut ever transversely, a little above the middle, will form young bulbs in abundance near the margin of the outer coat. This has been successfully practised with hamanthus pubescens, and several of the more rare orinothogalas. The grand art in cultivating bulbs is, to attend to the proper time for putting them into a state of rest; and when they are in a growing state, to place them so near the light, and afford such a supply of air and water as will enable them to bring their leaves to perfection. The management of exotic bulbs is, in general, very imperfect among gardeners, who cannot be too much impressed with the importance of attending to these two points, the perfecting the leaves, and the putting the bulbs into, and keeping them during a proper time, in a state of rest. Bulbous-rooted plants associate almost as ill with all others as succulents do; and, therefore, wherever a good collection is kept, there should be a house entirely devoted to their culture. The roof should be low and not very steep, and the pots should be kept on a level stage or plat-

form, raised table high, or about two feet and a half, that the flowers may be near the eye. A house, glass on all sides, with a central platform, six or eight feet wide, and two side ones, or side borders, about three feet wide, would form an excellent house for plants of this description, as all of them would be near the glass, and near the eye of the spectator. Whenever the bulbs, cultivated in such a house, became in a dormant state, they could be removed to a pit or frame of proper temperature in the reserve-garden, and kept there dry, till the growing season. Exotic bulbs require nearly the same degree of heat, when lying dormant, as they do when growing.

6661. Propagation and culture. A small house, constructed like a bulb-house, should be devoted to these plants; some of which are of considerable beauty: but they do not ass well with woody and ever-
green species. All the difference between the culture of hardy, and exotic herbaceous plants, consists in the latter being kept in a different climate and in pots.

Sect. VII. Of Selections of Green-house Plants for particular Purposes.

6662. The particular purposes to which green-house plants are applicable are few com-
pared with those for which plants which grow in the open air may be selected. The most hardy species will be found arranged as frame plants; the most showy and odoriferous under the first four sections. There are scarcely any green-house aquatics; but a few marsh plants; and no parasites, or air plants, suitable for the green-house, have been introduced hitherto. Collections, however, might be made of such as are grown in their native countries for useful or economical purposes, and whose produce is imported to this country, as of Laurus camphora, the camphor-tree; Pistacia lentiscus, the tree which affords mastich; of such as are highly odoriferous, as Verbena, Heliotropium, &c. In a botanical collection, Dionaea and Sarracenia are plants of great rarity, and difficult to pre-
serve or propagate. They are generally procured from their native countries, and grown in peat-earth, kept moist, and the atmosphere also rendered humid by covering them with a hand-glass. Cresswell has produced very strong plants of S. purpurea, by treat-
ing it as a stove plant. Under his management, “it is planted in a mixture of the fibrous roots, obtained from peat-earth, with an equal quantity of rotten willow wood, broken into small pieces, by which the soil is kept perfectly drained. The pots in which the plants grow are kept in a shaded part of the stove, and watered occasionally, but they do not require to be placed in pans of water, except they become so dry as not to absorb the water given in the usual way.” (Hort. Trans. iii. 360.) Some fine specimens of these genera, and also of Nepenthes distillatoria, are contained in the collection of Messrs. Loddiges, at Hackney.

CHAP. XIII.

Dry-stove Plants.

6663. What are called dry-stove plants are such as from experience have been found to require an intermediate degree of heat between the green-house and bark-stove plants and a more dry atmosphere than the latter. Their propagation and culture is the same as for green-house plants; with this difference, that they are not in general removed to the open air during summer; but where the construction of the house admits, the sashes may be removed in dry weather during the three warmest months, but always replaced on the commencement of heavy or cold rains and boisterous winds. We shall arrange them as woody, climbers, succulent, bulbous, and herbaceous plants. To cultivate them to any degree of perfection, it is essentially necessary that a house be appropriated to each section; and each house so arranged as that the plants may be near the glass, and that heat and air may be supplied at the pleasure of the cultivator, or a long narrow house may be divided so as to keep each class separate.

6668. HERBACEOUS DRY-STOVE PLANTS.

CHAP. XIV.

HOT-house, or Bark-Stove Plants.

6669. Bark-stove plants are such as require the highest degree of heat, which has generally been given by the aid of a bed of bark or other fermenting substance, in which the pots containing the plants are plunged. Sometimes, as before observed (6184.), steam or flues are applied under a vault covered with earth or sand as a substitute for bark; and more recently the pots have not been plunged in any material nor bottom heat applied, but a greater atmospheric heat communicated, and the atmosphere about the pots kept moist by watering. &c. We shall arrange the most ornamental species which flower freely under woody, climbing, bulbous, perennial, annual, aquatic, reedy plants; and add some remarks on palms, air plants, and ferns, which, though they seldom flower in this country, or for the greater part have flowers of little show; yet are grand or interesting specimens of vegetable beings.

Sect. I. Woody Bark-Stove Plants.

670. WOODY BARK-STOVE PLANTS.

6671. Propagation. All the known modes are occasionally adopted, but those by seeds and cuttings are the most general. Few stowe plants ripen their seeds in this country, and such as are obtained are therefore generally procured from abroad.

6672. Tropical seeds in general, Cushing observes, are very liable to lose their powers of vegetation by the transition from warm to cold climates, combined with the length of time which commonly intervenes between their gathering and arrival with us, especially if they have been exposed to damps; on that account they should be sown as soon as they arrive, at least a parcel each. Much depends on the state of the seeds when received. East and West India seeds generally arrive with the regular fleets, as indeed do those from the Cape of Good Hope, and all the South Sea Islands, for the most part by the Eastern and China ships; so that one may in general be prepared against their arrival. As early spring is undoubtedly the best time for sowing, a few weeks' delay may in some instances be advisable. If received late in October or November, wait until January, or perhaps February, unless it evidently appears that they will not keep out of the earth so long. For ripening in a vegetable state, much care is required, as, it is sometimes seen before August have a good chance to acquire sufficient strength of growth to carry them through the winter months, so as to deserve the general eulogy of young vegetable life.

6673. The pots being well drained should be filled with the compost suitable to the species of plant the seed intended to be sown has been produced (see the table); let it be pressed down to about a third or half an inch below the edge of the rim, according to the size of the seeds; if they are small or slight, it will be necessary to press it pretty tight, and to put a little of the very fine-sifted mould on which to deposit the seed, previously smoothing it with a bit of this flat wood, bents so as to lie on it. Being thus prepared, let the seed be sown regularly on the surface, and cover it from about eight to a quarter of an inch, according to the size of the seed as before, with the same sort of fine mould. But if the seed is of the largest sorts, as, for instance, the nut or stone kind, no more is necessary than to press them into the earth with the finger, and to cover somewhat thicker than is recommended for the others. In either case, the covering should be pressed moderately on the seed with the hand; which is indeed a most necessary caution in sowing seeds of any description whatever. In order to ensure the vegetation
of hard or very tough seeded shells, some have soaked in water for a few days, say a week, or even ten days, for such as happen to be very dry, previous to sowing: a shallow pan, placed on the coolest part of the house, is the safest and most frequent method, and immediately plunged in a strong heat, without which they will not be likely to vegetate; if a close dung hot-bed. A regular but moderate watering, steady heat, and occasional weeding, should any such appear, is all they will now require until they are to be removed to the pots; whilst they have attained a few inches above their cotyledons, or seed-leaves. There are some fruit, such as melicium, whose exterior coat is so very hard that the embryo plants are not able to burst through, at least, with us; to remedy which the knife is not infrequently used to pare them thin, even to making a hole, if it will serve the purpose, with the eye of necessity. Whenever are cuttings are performed in spring, or early in summer, the smaller sorts may be expected to vegetate in the course of five or six weeks at farthest; whereas, the larger bony kinds will sometimes remain dormant in the earth for the space of twelve months; this must be attended to, else one may generally find a change in the cuttings, and in some cases, they will decay. Whenever there is any doubt of their vegetating, let some of them be taken up and opened with a knife; when they will at once discover whether they are sound or not; if sound, they must be still kept in a strong heat, and regularly watered as before; for want of this simple precaution, valuable seeds are often carelessly operated on, when just bursting their shell or embryo; and not unfrequently, by that accidental check, are so materially injured as to prevent more than one half of them vegetating again; if they have been at all so fortunate as to be noticed and resowed. (Exotic Gard. p. 8.)

6675. By cuttings. Besides the usual supply of the different sorts of earth, &c. there is another article necessary to be provided before we begin the business of making cuttings; which is, a few dozen of small bell-glasses, (the white glass is best,) of as many different sizes as are the pots in which the cuttings are intended to be planted; they should be fitted to the pot, so as to rest on the inner side of it, about an inch below the rim; by observing which circumstance, when the pot is filled with earth, the glass will have room sufficient to sink a little into it, so as to perfectly exclude the external air; of very essential importance to the cutting while in a dormant state, that is, from the time they are put in until they begin to grow.

6676. The cuttings may be made almost every season of the year; yet the months of April, May, and June are certainly the most proper; as the plants are at that season plentifully supplied with young wood, which, in most species, produce roots when grafted into cuttings, or when planted into pots in the same manner. When the day is fixed upon for this business, let a quantity of pots of the proper size be selected, and prepare by covering their bottoms to the depth of one or two inches with pot-sand; and then, as wanted, about half filled with the compost best suited to the plant intended to be propagated, to go in at the back, and may then first stage protected; if they can be broccket, to insert the cutting in when ready. On the purity and cleanliness of the compost depends in a great measure the success of many of the tenderer kinds of cuttings, particularly those which are obliged to be kept in moist heat, as it is, when contaminated with other composts, very liable in these situations to fermentation, and the presence of parasites generally destructive to plants; and of the earths; and the properties of which are put in motion, by the application of heat. As an exception to this rule, may be adduced sand, which is of very great utility to mix with the loam, should it happen to be rather stiff for the nature of the cutting: but then, the sand proper for this use is of so pure a nature in itself, that it is evident it cannot have the effect noticed above in regard to mixed soils.

6677. In the choice of cuttings, preference should be given to the firmest wood of the same year's growth; and of these, only such whose leaves have attained their full size and proper color, which are generally to be selected from the shoots that lead in an upright, and not a horizontal, direction. The cuttings of many plants, if taken from the lateral shoots, never become proper stems; but are inclined at all times to form an irregular, bushy, weak head; this is not of small importance to such collectors as cultivate plants merely for the flower; as such leads generally prove unproductive and sterile the sooner than those which have been derived from the upright shoots, early in the season, before they acquire that luxuriance of growth so uniting for the purposes of propagation. The tops of the shoots are to be preferred, unless they happen to flag before used. To prepare them for insertion, most of the leaves must be trimmed off close to the stem, leaving only a few at the top, to allow a free respiration of the air necessary to the life of the plant. This is a most essential article in the making of cuttings, particularly those of evergreens, for if they are deprived entirely of their leaves, or that they otherwise flag, or occasionally fall off soon after they are put in, there will be little or no chance of their growing. This is especially the reason in the inherent sap of a plant, being deprived of these organs of respiration that kept it in motion, and the cutting having no roots by the efforts of which to produce new leaves, the sap, consequently, becomes stagnated in the pores of the wood; which, like the stagnation of the blood in animals, will in all likelihood prove mortal, by occasioning an instantaneous mortification.

6678. In shortening each cutting to the most convenient length, care must be taken to do it with a clean cut, in a transverse direction at a joint; and by no means should they be left exposed, or to lie any considerable time before planting. In this, a small difference is of great advantage, for if cut too short, they will not be able to vegetate; if, on the contrary, cut too long, they have. This is very large of the whole, but in general each species should be kept in a separate one, on account of the difference in time that some of them require to strike roots; and also, that any scarce or valuable kind should be put only one in a small pot, as they then are not liable to be injured so much by damp; neither in that case, is the use of the smaller propagating pans, or the precaution of putting them in separate glasses necessary. Should it be requisite to have a considerable quantity of cuttings made at the same time, it would be proper to have a one-light frame, with close glasses, placed on a moderate hot-bed, ready to receive them. It should be covered with sawdust or clean tan, about a foot deep, in which to put them, which, if only a few done, they may be plunged in any frame among other things, provided there is a moderate heat.

6679. Watering and shading. They will now require the most particular attention as to watering and shading. The water must be given twice or thrice very moderately until the earth becomes sufficiently moist, which, if once watered, will retain the moisture for a length of time, by being covered with the glass: but the shading is the principal care whenever the sun's rays fall on the glasses, as nothing will create rot.
tenness sooner than letting the leaves flag, and lie upon each other, which will be the positive consequence of a neglect of shade. The most advisable method to do it is, to have a few large sheets of strong paper to lay over the edges within a frame, which, at the same time that it shades the cuttings, does not prevent the sun's rays from entering the frame and clearing off any damp that may be accumulated thereon. If, as is almost always the case, we laid the frame entirely to the side of the frame, it is evident they will tend to have the direct contrary effect. Therefore, in the course of a week or fortnight, they will be able to withstand a little of the rays of the morning and evening sun.

4681. As the heat of the bed declines, it will be necessary to have another, properly tempered, ready, in which to plunge them when requisite; or otherwise, let the old one be renovated with linings of fresh wood, and managed in the same way as other cuttings in the bed; as it is better to do it often and but slightly at a time, it being but a trifling increase of labor compared with the probable consequences. By this management one may expect to have some of the fresh growth, if it has progressed, and, if at all, not more for hot-house cuttings, as they are not so liable to suffer from this cause as those of green-house plants.

4682. In taking the bell-glasses off at night, it is necessary to observe that from their closeness they sometimes occasion the cuttings, more frequently the harder sorts, to produce young leaves and even shoots, before they have sufficient roots; if at any time these should be mistaken for well rooted plants, and their glasses taken off accordingly, in a few hours they may be perceived by their leaves beginning to flag; in which case the glasses must be immediately replaced; otherwise, if neglected, these tender shoots will be utterly spoiled, and it will be a very great chance whether the cutting will ever produce more or not. If they are too much exposed to the cold, they will be otherwise injured to some extent, and dry off on the edges; as indeed all those which are growing; the glasses should therefore be more frequently dried, and kept off until the leaves, &c. which were under them, become dry by evaporation: lest we risk the cutting, I may say, by rotting the first weak efforts towards active life.

4683. The rooted cuttings being thus prepared, they may be transplanted into any of the frames just set in more exposed airy situations in the hot-house: but as some kinds require a much longer time to produce roots than others, it will be necessary to keep such still in the frame, shading and watering them when requisite, as already directed. This may be managed as follows: if the cutting be in the main in the cutting state, it will be advisable to have them taken to the propagation-stove, and plunged in the barb-pit; previously clearing them from any damps, moss, or weeds that may have grown amongst them. If the frames are kept warm, repeating this operation until the autumn, when, if for any such as the case, it will be necessary to give them a little air by taking off the bell-glasses at night, and to keep them a little moister than before. If they endure this prettily well for a few days, the glasses may be left off entirely; which will harden and prepare them by the time in which it may be thought convenient to pot them, as before directed.

4684. Refitted to parting and potting the rooted cuttings or seedlings separately, the greatest nicety should be observed; first, in turning them out of the pots without lacerating the roots; and secondly, in shaking and working the earth from amongst them, until they can be readily parted without breaking. If any of the mould can be conveniently preserved to them, so much the better; but the preservation of the root is the principal object in this operation. The clump must be fitted to the size of the cuttings, and neatly tied up, if necessary; let them be then well watered with a rose-pot moderately fine, but by no means should they be flooded, or slushed with it, as too many are apt to do, but let it be given gently, and time allowed for it to soak regularly into the mould. They will require a brisk heat and close shading for a few days, until they have established themselves in the fresh mould. (Exotic Gardener, 20.)

4685. Laying and inarching are rarely practised on hot-house plants. However, there are some that do not produce roots freely by cuttings, which may be multiplied successively by these methods.

4686. In laying, choice should be made of the young tender shoots of the present year; the soft bark of which, and the small size of the plant, render it particularly necessary to observe whether the plant intended to be laid is of a brittle nature or not; for if it is, it will be necessary that the shoots be pegged gently down to the surface previous to laying, and then left until their tops naturally acquire a perpendicular direction, which they will do in a few days; with which aim would be difficult to cut without wounding or cutting them off; but if treated in this manner, the most brittle may be laid without danger. It is a conclusion drawn from several experiments, that the layer, which is inserted to a proper depth, roots sooner and produces more shoots than which; the reason therefore is, that a good root is necessary to make the shoots larger, and a better excluded, and there is a more regular degree of moisture for the nourishment of the young fibres, when they make their appearance. No part of the shoot should on any pretence be covered with the mould, except that which is intended to produce the roots, as covering the whole renders it extremely liable to be injured; and therefore, if any particular tender plant should happen to the contrary, it would entirely endanger the whole stock.

4687. Inarching is much preferable to the common grafting, for evergreens in particular; it is principally suited to the genus of cane or cane-like plants, and all plants having the same species of habits; because their strong leaves, if only for a few days deprived of their regular support, by being cut clear from the mother stock, if not covered closely with a glass, will be certain to wither and fall off; after which there will be but very slender chance of the scion's completing a union; it is performed as follows: having provided a stock, which should always be some of the earner free kinds of the same genus of plants, and nearly of the same diameter as the shoot which is intended for inarching; cut a
PRACTICE and yet the when, if be as thin 924 ting, In therein, support free comes the thereby will to do of indeed. If much later, most of them will be in a vigorous state, and it will require infinite care, and increase of labor to keep them properly shaped, else the intense influence of the sun on them, at an advanced season, will have, though a different cause, nearly the same effect; they need the same to fully develop the character which they have made the first effort for the season's growth, the fibres being set in motion, and not having a top full of young tender leaves to support, they soon find their way into the fresh mould; and the plants, by being thus taken in time, and when done, placed in a bed of the good, free or coarse, and in general, able to support themselves against the strongest rays we may reasonably expect at that season, without much danger to their leaves.

6689. **Operation of shifting.** Being fully prepared for the removal of the plants, let a part of them be taken to the potting-shed together, that they may be no longer than necessary out of the stove; and while these are shifting, the remainder may be taken out of the tan, and set on any of the shelves or benches that are on the flues, so as to allow sufficient room to have it forked up and turned; and should it be sunk considerably below the desired height, some fresh well dried sand should be added, and mixed well with the old in turning; when done, let it be made pretty level with a rake that the plants may be conveniently and regularity set on the surface when shifted. In shifting the plant, the greatest nicety should be used not to injure the roots; because, if the roots, from a multiplicity of wounds, (which, once become callous, or consolidated in any manner, the branches must also be expected to suffer and decay.)

6691. An old but erroneous practice followed by many, is that of paring off the best part of the roots with a knife; that is, the tips or ends of the fibres which are on unusually the active part in collecting the food for the stem, &c., then, without ever loosening the remaining part of the ball, set in the new pot with a little fresh earth thrown loosely about it: as a matter of course, they think it must then be completely drenched or flooded from the waterpot; and, lastly, to crown the whole, to have great care to see that it is well settled, to which they have reduced the roots, it is impossible they could ever conceive to be in a state fit to undergo such treatment with any kind of advantage: but it is the misfortune of many, who will not for a moment hesitate to take care of tender and curious plants. The practice is easier to understand than to follow, as the old track of cutting and watering, the same as they may have be seen practised on the hardiest geraniums or myrtles. Though the method may not seem to hurt some few kinds of strong free-growing plants; yet it never can be allowed as the true one, because a portion of roots of both is destroyed by this practice than by any other particular part of the system of management which some so blindly follow. There are instances, however, wherein a knife is necessary to the roots as well as the branches, viz. when they become rotten or otherwise contaminated; and also to such as are propagated by cuttings of the roots, as most species of geranium may be, some minnows as, and indeed any that are observed to produce suckers; in all which cases they should be taken off with precision, and a sufficiency left to support the parent, if considered worth preserving.
WOODY BARK-STOVE PLANTS.

6692. In turning the plant carefully out of its pot, observe if the roots have perforated it in any part, so as to render it impossible to part them without breaking the one, or lacerating the other; in which case expect the former as the slightest damage; however, when the ball of roots is divested of its pot, let the plant be laid in a vessel, under a layer of water, for 24 hours, that the fronts may have time to form, without tearing off the roots that may have grown amongst them: also any caked or mossy substance on the surface, which will come easily off with the fingers. Then proceed to loosen the earth and matted roots, by gently pressing them on the ball with the hand; or otherwise, by pressing it so as to operate on the roots of the plant without cracking the pot. Should the root of a very large sized pot, ready prepared, put in a quantity of the fresh mould sufficient to raise the crown of the roots to about half an inch below the rim of the pot, on which set the plant; and add more earth, lightly shaking it in from the bottom of the pot, in a moderately light manner, so as to raise the stock to a great degree, nor by any means using a stick for this purpose, another never-failing attendant on the former practice, by which the roots are extremely liable to be torn or bruised; add mould sufficient to raise the surface level with the rim, as it will settle to a proper depth with watering, and smooth the whole off near the hand.

6693. Two or three assistants will be found necessary, where there is much of this work to be done; one of those should be employed in supplying pots and other necessary; the others in washing and cleaning the plants after their roots have been taken off, and pressing them up properly to their sticks afterwards; new sticks should be had at least once a-year, to hot-house plants in particular; as the old ones very often harbor more or less of the several pestiferous insects which infest these departments. This done, let the plants be set on a level spot together, and moderately watered with a fine-rose pot, held at a distance of at least a yard from the pot, or pots, as a great degree, nor by any means observe to give no more water than is sufficient to settle the fresh mould to the roots, and by no means to slush or give the surface that puddled appearance, so very disagreeable to be observed in departments where neatness should be the uniform and leading principle. Having thus finished the first division, let them be immediately taken to the stove, to be set on the fresh-turned tan for the present, and those that remained there, taken to the shed to be treated and shifted in the same manner as the others.

6694. When the whole are shifted, they may be partially plunged for a few days; setting the pot about half full of water, so as to cover a larger part of the tan, to prevent the plant from being injured by its roots touching the jambeaux, which is frequently the case, when it has been recently turned or augmented. However, there must be a pretty brisk fire-heat kept up in the house, until the plants recover from their inactive state, the unAwareness of their roots, and the so recently disturbed. They will be much benefited at this time by a moderate use of the hand-syringe, in the morning before the sun has begun to act on them with force; also by raising a strong steam in the house, to be done by throwing water on the tops and sides of the warm flues. But when they are freely treated in this manner, they require but little freedom in water, and are general to be kept no more dry, than it is necessary to prevent their leaves from becoming particularly so, than when they have been lately shifted. However this must unavoidably depend on the judgment of him in whose care they are placed; as some of them will require considerably more than others. When, then, the plants are restored to their pot and violent heat is over, the plants may be plunged neatly in the tan up to the rim; but observe that it is not left scattered on the top of the pots, as it would disfigure the work an extremely slow appearance; a few inches of clean sawdust laid over the tan, gives a clean and neat appearance, which, in most gardens, is a particularly essential part of the curator's concern. In the plants which require the aid of Ian-heat, being properly plunged, and when it is necessary to draw them up again, and when they are one or more seasons advanced in growth, their tops will require a little more freedom than the others regulated on the different benches or shelves; let the place be well cleaned out, when little more will be necessary for a few weeks than watering when requisite, squirling, steaming, and attention to the departments' greatest necessary are to be kept in the house at this season. This should in general be about sixty degrees. If it is kept much lower, it will considerably retard their growth, and if any degrees higher, the free-growing kinds will soon over-top, and materially injure the weak and more tardy sorts unless prevented; besides themselves becoming unsightly, the consequence of being drawn, or forced into weak ungainly stems.

6695. Insects. As the heat increases with the advancing season, the different species of insects to which these departments are liable, will multiply incredibly. Those which seem to make the greatest havoc amongst plants in the hot-house, are, the green fly, the thrips, the mealy white bug, the great scaly bug, the small scale, or the pine-bug, and the red spider, which, although the smallest, is by far the most destructive of any of the species that exist in these departments.

6696. For the fly and thrips, there is no process which seems to take so much effect on them, as a strong fumigation of tobacco; repeated twice or thrice, according to the strength the insects may have attained.

6697. For the bugs, there is none of the several expensive methods mentioned in different authors so effectual, as simply picking them off, or this may be said to be tedious, but then it has sureity to plead in its behalf; besides, that the plants in no manner disturbed by the operation; let a person be observed in looking for them, examining plant by plant, and leaf by leaf, from top to bottom, and also any incisions or cracks that may be in the bark of the stem, &c. there will be a constant and tiresome employment; on the contrary, if regularly done, one operation will be of more service than five, if it be executed in a careless inattentive manner. As each individual plant is picked, it should be carefully washed with a strong linctum of soft soap and water, which will have a powerful effect on their eggs, which in general sufficiently small to elude the eye, or perhaps so situated within the young buds that they cannot be smelt without injuring the plants, which will, however, penetrate into these secret holes, and in general be fully adequate to their destruction.

6698. When the plants are out of the house in summer, every one of them should be well washed with strong infusion of tobacco, as, unsteady; and such a smoking, of tobacco, or tobacco, has been infused; in particular, all the joints of the wood-syring, and whatever name-holes or other crevices may happen to be therein; as in these places some of the species, more especially the white mealy bug, is much inclined to retire itself for breeding. This operation will, however, if performed in spring and autumn, be a great means of their extinction, and will tend in a great degree to check the multiplication of the others.

6699. The red spider, the last and most pernicious of the species mentioned, is to be overcome next, by a strong infusion of free hot well directed use of common water; either by steam or with the hand-syringe. The steam, by giving a finished form in the aze, prevents the bees from extending its slender web from leaf to leaf, and thus checks its progress; while the syringe, by suction, breaks the ligaments of those already made, and in most instances washes the insects to the ground, where, if properly done, it may return them to the ground, and so prevent them from appearing again.

They will sometimes, however, elude the greatest diligence, for a while, by collecting under large horizontal leaves, which serve them as citadels against the attacks of the water; but here they will be found and driven from their retreats, by extracting the liquid substance of the leaf for their support, in consequence of which it loses its verdure and becomes consanguineous; this, when found, should be picked off, and taken out of the house immediately; for if left anywhere among the plants they will in a little time establish themselves on others. If they happen to be discovered before the leaf has lost its beauty, they may be rubbed off with the hand on a sheet of paper, and expedite the process. If at any time the quantity...
PRACTICE

therefore, as observing unless " and in and which but however, and kept serving upon which probable, mended ger ders of the middle son of the principal atmosphere at the observation of the sun's heat in the dawn of the day's rising heat of the sun, and its influence over the atmosphere. It is by syringing, partially when dry and warm; for if administered in the morning, the rising heat of the sun exalts it, before it has time to diminish. It is much moistened in the course of the succeeding day, and is liable to much injury, being left in an exhausted state until the following morning, and which, it is probable, may not prove more fortunate; whereas, if administered in the evening, it refreshes them the next day, and reduces them to a healthy state in the morning. Besides, by being left in an exhausted state, the following day, and which is, therefore, much more dangerous than if done in the morning, than if done in the evening. But as extreme is dangerous, care must be taken to use no more watering than is necessary for the health of the plants; for if used to that degree, the earth becomes sour and deprived of its vegetative powers, the consequences may be rather unpleasant.

By thus setting the plants in the green-house, it tends to prevent the increase of insects; also their too luxuriant growth during the summer months. After hardening them, and freeing them from the small and crowded frames, it is more likely to bloom; which is, in these ornamental plants, the principal object of the cultivator, besides that they are not so liable to be injured by the severities of the succeeding winter.

6706. Autumn treatment. Towards the latter end of August the natural heat of the atmosphere will be on the decline; therefore, except on particular fine days, when a small portion of air may be given, the lights must be kept perfectly close; but more especially so at night: as we have frequently at this season heavy chilling dews, and are also often surprised with unexpected showers of rain or hail; to admit either of which might be very injurious to the plants; however, by shutting up the house before the rain has withdrawn its influence entirely from them, and thereby warming the enclosed air, they may safely stand here some days longer.
6707. As soon as the month of September commences, it is time to think of getting the stoves ready for their reception; first, a quantity of fresh tan should be provided, sufficient to raise the bed at least six inches above the kirb or wall of the pit, in conjunction with the best of the old already there, which is to be extended, or made out to dry, from the new and old tan, and then covered with a convenient yard, for two or three days, where it should be regularly turned twice or thrice a-day, and covered with mats at night; while this is preparing, let the flues of the house be well cleaned and the walls white-washed; an operation necessary to be done every year in these departments, where strong fires are kept for some time. As the tan can be sifted in the common way, it can receive the form of a riddle or sieve: some gardeners throw it entirely away, but the part sifted being mixed with the new, prevents its heating so violently as it otherwise would when first put in; it also tends to preserve a more regular heat within the house, if used in this manner. It would be used only in its sifted state, consequently, like most other things that are worked up above their pitch, liable to be sooner exhausted in proportion to the first foundation.

6708. Having sifted and got away all the refuse of the old tan, let the fresh, if well dried, be immediately cast into the pit, and both well mixed together in the pit; still adding, until the bed is raised to the proper height; this done, let the wood and glass-work, kirbs, passages, &c., in short, every part of the house be diligently washed; for the twofold purpose of endeavoring to clear it as much as possible from insects, as flies and house-bugs; the appearance of these insects being thus removed, and the house, observing to examine each of them diligently lest any of those plagues so often mentioned, should find their way back to the store.

6709. The pots must not be plunged in the tan at first; as well on account of the danger of the violent heat injuring the roots, as because this early plunging might start them into a fresh growth; which, at this late season, would not be at all to their advantage. They must, therefore, be set on the surface of the pit in regular order, where they may stand twelve or fifteen days, or perhaps longer; being guided in this particular by the state of the atmosphere abroad, as well as the internal temperature of the heat in the pit: by the first week in October, the heat of the external air will be considerably abated, and that in the pit sufficiently moderate. The time for plunging being fixed on, observe to have it done in the most exact manner, placing the tall plants towards the back or centre, and the lower ones to the front or side of the house, in the form of the order at first adopted. If sawdust is used, it will contribute much to their cleanliness, and also make a more agreeable appearance than the tan. All being set to rights, and the passages, &c., swept clean, give the plants a good water, and you may have assurance of a proper removal, which will complete the business for this time. The principal care afterwards for a few weeks, is to give them a reasonable share of fresh air and water, according to the temperature of the weather; but it is more proper to perform the watering, syringing, and steaming, from this time to the beginning or middle of May, in the usual way, as being advisable to the plants. Let the bed where it is found covered with coarse grass be removed, by means of the bed, unless being injured by it: should it be done in the evening, the air in the house would unavoidably get chilled, especially in frosty weather. It is even necessary that the water used for this purpose should be nearly of the same temperature as the air in the house.

6710. About the middle of October, it will be necessary to add a little fire-heat at night, beginning with slow fires at first, and gradually increasing them as the severities of the weather increase. Although a circulation of fresh air of earth is at all times requisite to the health of plants, yet the heat of the external atmosphere will make it so much the less necessary, and the danger of the air being too much heated considerable; in fact, none should be given, except on particular fine days, when the front or end lights may be opened a few inches. They should be shut early in the day, seldom permitting them to remain open longer than one o'clock; thereby giving the sun time to warm the fresh-admitted air before its admission. This will be a little more necessary in the middle of October until the beginning of April: as the strong cold winds which generally blow during the winter months find of themselves but too many entrances.

6711. The watering in the autumn, discontinue it to those plants plunged in the pit, as the moisture of the tan, added to that which proceeds from the syringing, will be found quite sufficient for most of them; on the contrary, those over the flues, or on the shelves or kirbs near the fires, will require an additional portion on account of the strong fires necessary to be kept when the weather happens to be severe. The use of the syringing and steam must also be stopped in the severest fronts, lest by that means the house should get over chilled; however, they may both be used freely, when the weather proves moderately mild and fine; but by no means is it to be understood, that the house at this time is to be kept in a continual mist; or to be considered as unhealthy, as usual, or even more so in the mildest weather, especially when in want of it. It is necessary to notice that those plants which are inclined to be deciduous, and also some of the more tender ones, will be occasionally dropping part of their leaves; these should be picked off as soon as they appear, otherwise they will have rather a disagreeable appearance among the plants.

6712. Winter treatment. About the middle or end of December, it will be necessary to have the tan in the pit turned, and renovated with a little fresh well-dried bark to enliven the heat, as the severest part of the season is still to be expected; however, in performing this work, great care is required that the plants are not chilled or injured by being removed out of the tan-bed at this cold season: therefore, the mildest weather must be chosen for performing this operation. The pit being cleared, immediately proceed to turn over and mix the old and new tan well together, in which, as soon as it is completed and levelled fit to receive the pots, they may be plunged without delay; as there is not that certain danger of a burning heat ascending now as in the summer months, in which season the powerful action of the sun occasions it to ascend more violently.

6713. Plunging the pots. Should it not be convenient to have the whole plunged the same day, those left will require to be set on the surface of the tan during night; lest by being left near the glass, or exposed to any injured crook, they might be injured by the cold wind; and, with the utmost care, they should be kept in a short a time as possible out of the tan at this season, they should without fail be plunged the next or following day at farthest: it will be also requisite to keep a pretty brisk fire-heat in the house, in order to have the pots are covered, and until the bottom heat in the pit becomes sufficiently strong; else they will be liable thereby to drop, and lose many of their leaves in consequence of being checked at this season. Should it happen that a series of clear fine weather follows this operation, the action of the sun may possibly occasion the heat to rise rather violent in course of a few days after being removed, which symptom, if not carefully attended to, can be immediately remedied by lifting the pots out of their places, and throwing into the hole a small quantity of the surface tan; on which the pots may be again set in a loose manner; thus, by permitting the heat to pass freely off by the sides of the pots, it prevents its burning the earth or roots, which would be certain death to the plants: when its violence has subsided, let the pot be levelled, and pots properly replunged; but unless the weather, as already noticed, happens to be particularly clear, in all likelihood this labor will not be encountered.
6714. **Watering and cleaning.** They will require from this time until about the beginning of March,nothing more than the usual care of watering when necessary, and cleaning them from all dirt or insects as soon as they appear; also to keep the temperature of the enclosed air as near to its regular pitch as possible: to assist in compassing this object, when the weather sets in severe, it will be proper to use either shutters of canvas or bass mats to cover all the lower parts of the house; and in particular those at the greatest distance from the entrance of the fires every night; otherwise the frost will easily enter these remote parts, and chill the air through the whole house; the consequence of which may be very injurious: on the other hand, if these precautions are not attended to, there will be a necessity of keeping up a very strong fire-heat, which will likewise be attended with pernicious effects.

6715. **Insects.** It is in these intervals that that destructive insect the red spider makes the most rapid progress, on account of the necessity there exists of keeping the houses close, and supporting a dry warm air, both of which circumstances are particularly congenial to its nature; therefore on all fine mild mornings, observe to raise a powerful steam in the house as already directed; by the frequent repetition of which there will be a possibility of keeping them under control.

6716. ** Refreshing the bark-bed.** As the internal strength and heat of the tan will now be much on the decline, in consequence of the length of time it has been in use, it will be requisite to turn it more frequently, so that about the beginning of March, it should be again stirred to at least half its depth; which will afford a temperate heat, until the time in which the plants are usually shifted, when it is generally renewed. Some gardeners make it a practice to have merely the upper half of their tan-pits stirred at any time throughout the year, when the heat happens to be on the decline; this is certainly a very proper method where there is plenty of time and hands to perform it; as there is no danger of a burning heat arising; but it requires to be done so much the oftener, such heat seldom lasting above a month or six weeks; it consequently will not answer where these conveniences are not to be had. The plants being regulated in proper order as before, let them have the usual treatment until the time of shifting. (*Exotic Gard.* p. 70.)

6718. **The propagation and culture adopted for green-house climbers, is equally so for those of the bar stove, the difference of temperature being taken into consideration.** (*See* 6204. and 6253.)

### Sect. III. Bulbous-rooted Bark-stove Plants.

6719. *All bulbous-rooted stone plants* may, no doubt, be kept in the dry-stove; but if it is wished that they should flower in any degree of perfection, they must be plunged in the bark-bed, when newly planted. The same remark will apply indeed to most of the dry-stove bulbs.

6722. The propagation and culture of these need not be entered on, being essentially the same as for hardy or green-house herbaceous plants, the difference of temperature being taken into consideration. Such as have tuberous roots must be treated on the same principle as tubers in the open garden, as, for example, those of fumaria cava, erythronium, &c. which have their regular seasons of rest.

6723. The gloriaeaeae, that grand, beautiful tuberous-rooted stove plant, for want of attention to the nature of its roots and its habits of growth, seldom produces flowers in this country. "Its failure," John Sweet observes, "arises chiefly from the defective method in which its roots are preserved during their inaction, and from the want of proper treatment, when they first vegetate in the spring. Injured at these periods, the plants generally continue through the summer, weak and unpromising, throwing up only a few small stems, which do not flower in sufficient strength and beauty. Under the following management, Sweet has had perfect success, and has known a single root grow ten feet in the course of a season, with numerous blossoms upon it. When the stalks and foliage have decayed in the autumn, and left the root, like a well ripened potato, in a dormant state, the pot containing it must be removed from the bark-bed to the top of the hot-house floor, at some distance from the fire, the warmth at this time necessary being merely what is sufficient to keep the earth in the pot free from damp; and to prevent the waterings of the house, or other moisture, falling on the earth in the pot, it should be covered, by inverting upon it another pot of the same size; or if larger, it must be hung over its edges and more effectually exclude the wet.

If the roots are small, two or three may be placed together in the same pot, whilst in their dormant state; but if they are thus shifted, the mould must be well shaken down in the pot, in order to prevent the access of air to them; the old mould in which they must grow must also be used; for fresh earth or sand would stimulate them to move too early. About the second week in March, the roots must be planted, putting one or two, according to their size, into pots measuring six inches over. The best compost for them is fresh loam, mixed with an equal quantity of bog-earth of good quality: the loam should be good, not over rich with dung, nor too heavy. The roots are to be covered about six inches deep, and care must be taken not to break them, unless nature has shown where it is practicable to divide them easily. The pots, when filled, must be plunged into the bark-bed, where the heat should be equal to ninety-five degrees of Fahrenheit's scale. Water is to be given very sparingly at first, and though, as they grow, they will require a more liberal supply, yet it is necessary, at all times, to be very moderate in giving it. The heat must be well kept up, and as the shoots extend they must be supported by sticks, or trained in any direction on wire or cords. (Hort. Trans. vol. ii. 23.)

6725. Propagation and culture. They are all propagated from seeds, most of which ripen in this country; but some few sorts are continued by cuttings for the sake of preserving particular variations. Sow in February or March in pots, to be plunged in a hot-bed; prick out the plants into the smallest-sized pots, when they have attained one or two proper leaves, and shift them once or twice into pots a size larger in the manner recommended for the bulbous (II. 3); keep the plants in hot-hoods or pots ready to blossom, when they may either be removed to such of the houses as are empty at the time, as the bulb-house, green-house, &c. or assembled in a house devoted to annuals. Some few of them, as the ice-plant (Mesembryanthemum crystallinum) and egg-plant (Solanum melongena), may be plunged in a warm situation in the open garden.

of
the
natural
arts;
orders of such rare sorts as have not yet flowered. The following are some of the most remarkable of the economical tropical plants used either in their native countries or imported into this country.

**Foods.**

1. **Bengal quince** (Ripogonum undulatum). Sows up (Lasioglossum acuminatum).
2. **Alligator-apple** (Manihot utilissima). Balsam-tree (Eugenia uniflora).
4. **Ackee-tree** (Blighia sapida). Black-tree (Ficus sycomorus).
5. **Cocoa-plum-tree** (Chrysobalanus icaco). Blossom-tree (Cordia alliodora).
7. **Cocoyut-tree** (Cocoea subsessilis). Bloodwood (Haematoxylon campechianum).
8. **Coffee-tree** (Coffea arabica). Blue-fig-tree (Ficus australis).
10. **Calabash-tree** (Crescentia cujete). Buckthorn (Rhamnus cathartica).
11. **Nogo-palm** (Quisquina revoluta). Buckthorn hull (Coccus ussuriensis).
12. **Bread-ruuk-tree** (Chrysophyllum dulcis). Buckthorn tree (Rhamnus frangula).

**Some mind relies nothing that is not immediately useful, or has some relation to utility:** to such the foregoing list will be of some value as pointing out plants of great importance to mankind in other countries. From our connection with these countries, and the number of young persons that annually leave Britain to pass great part of their lives in them, it is desirable those plants should be known here also; and hence a national object for the patriot, who has wealth and leisure, to display them in a conservatory attached to his castle, or palace, (fig. 623) of suitable elevation and extent.

673. In selections of rare or curious plants, or such as are sought after chiefly by botanists, the palms, the air plants, and the exotic ferns will be included; and on the culture of these, we shall select some remarks from the Horticultural Transactions.

674. The **palms** is a natural order of plants of great interest by their utility, both as fruit-trees, and as supplying other products; and of much grandeur of appearance. The cocoa, sago, and date palms are well known; upwards of fifty other species have been introduced into this country, and are to be found chiefly at Messrs. Lodige's. A number more remain to be procured, of which the dome-palm (fig. 624) is one of the most remarkable, being the very palm known to have a branched trunk like other trees.

675. The **culture of palms** is less a matter of nicety, than expense. They require a powerful moist heat, a large mass of rich earth in the pot, tub, or bed, and ample space for the leaves. As they are of remarkably slow growth, a store devoted to their culture does not require to exceed the common height at which the trees-palms to display their character, it would require to have the roof elevated by degrees to 60, 80, or 100 feet. It is much to be wished that some spirited man of wealth would, in these times of peace and leisure, distinguish himself by palm culture, of which Messrs. Lodige's, much to their honor, have set the first example. It is a common opinion, that their growth is so slow, that little effect is seen in their trunks during a life-time: but this every gardener that has supplied his palms with abundance of space for the roots, and adequate heat in their atmosphere, can witness against.

676. **Parasitic stone plants.** Maria Graham (Letters from India) remarks, that she saw many of these flourishing in great luxuriance on the rough trunks of palms in the Calcutta botanical garden. At Kew, Spring Grove, and in the garden of the Horticultural Society, they have been...
generally grown in rough tan, closely pressed together in small pots or baskets, and suspended from the roof of the hot-house. Messrs. Lodigeus have established some specimens on the trunks of palms in the Indian or natural manner, and the Honorable and Rev. W. Herbert appears to have been equally successful. "I am informed," he says, "by a friend at Calcutta, that he cultivated with great ease, all the dendrobium aeraidi, and other parastatical plants, by tying moss into bunches, and placing them on the edge of a branch, and placing above them a pot of water with a hole at the bottom, through which a string passed, nearly as large as the aperture, by which the water was gradually and continually conducted to the upper part of the parastatical plant, which it afforded with the most convenient moisture for its purpose best. He mentions that dendrobium aeraidi, fastened to a tree and irrigated in this manner, will, in a little more than a year's time, produce pendulous racemes of flowers, from two to six feet long, and it appears likely to thrive with me under the same treatment. I had previously found no difficulty in establishing epipendrum on the stems of the tree in the roof, by cutting a notch in the bark and inserting the plant like a graft, and tying moss about it to support it, till the young roots had attached themselves to the bark; but from want of sufficient moisture, they have not made much progress, or flowered with me. I have now adopted the above-mentioned mode of treating them, with full confidence that it will succeed in my stoves, as well as it does at Calcutta; and very soon after its application to a sickly epipendrum, growing on the stem of Stereulla balanghas, vigorous young fibres began to sprout from it on all sides. I am very much inclined to think, that most of such plants would attach themselves to the sides of a porous stone or vessel, should be kept root, if constantly irrigated, and thrive upon them as well as upon a living tree, especially if the stone or root were covered with growing moss, for I have observed the fibres of more than one sort attach themselves strongly to the outside of the pot in which they are planted; and I conceive that they might be beautifully cultivated, upon an ornamental cone of porous pottery, filled with water and furnished, on the outside, with niches, in which the plants might be fixed, with a little moss or peat to promote their growth in the first instance. I have found the parastatical plants in danger of perishing, from want of moisture, on a deciduous tree, during its season of inactivity, but that deficiency would probably be removed by constant irrigation."

```
765. The Rafflesia Arnoldi is the most extraordinary parasite known to botanists. It was discovered by the late Dr. Arnold, in Sumatra, in 1818, in a jungle or thicket, growing close to the ground under the bushes, and attached to the roots of species of various plants. The plant consists of the flower only, having neither leaves, branches, or roots; the flower is a yard across; the petals, which are subround, being twelve inches from the base to the apex, and being about a foot from the insertion of the one petal to the opposite one; the petals are from a fourth to three fourths of an inch thick, and the stamens, as long as the petals, held together. It appears to take its origin in some cramp or hollow of the stem, and soon shows itself in the form of a round knob, which, when cut through, exhibits the infant flower enveloped in numerous bracteal sheaths, which successively open and wither away as the flower enlarges. A singular change takes place in the vessels of the root or stem of porous pottery, filled with water and furnished, on the outside, with niches, in which the plants might be fixed, with a little moss or peat to promote their growth in the first instance. I have found the parastatical plants in danger of perishing, from want of moisture, on a deciduous tree, during its season of inactivity, but that deficiency would probably be removed by constant irrigation.

```

767. Exotic ferns. The tree-ferns, Humboldt informs us, are of singular beauty in their native sites. Only a few species of these, as Polypodium arboreum, Davilla pyxidii, Pleis aculeata, &c. have been introduced; but the number of herbaceous ferns which are store plants is considerable. They are propagated from seeds which generally ripen freely in this country, and such as are received from abroad generally grow, however long kept; they are also multiplied by dividing the roots. The best of these species of exceptions, which have been raised from seed by the wood Shepherd, the assistant curator; and the following are his directions for this purpose: Having provided a common garden-pot, four and a half inches in depth, and half a wide, let the bottom part, to the height of one inch, be filled with fragments of broken pots or gravel. Over these should be spread a stratum of such soil as is commonly used for potting green-house plants, of the depth of two inches; the remaining half inch should be filled with brown loamy earth sifted through a hair sieve, the surface being made perfectly smooth, and on this the seeds are to be scattered as evenly as possible. Care must be taken that the wind be not strong when blowing the seeds away, leaving nothing but empty capsules. The seeds being sown, no other covering is requisite than a bell-glass, which should just fit within the rim of the pot, so as to exclude all air. The pot is then to be kept in a pan always half full of water, and set in a shady part of the stove or hot-house, being always regularly watered, and the cover directed. When the plants have acquired their root they are to be put into pots of the above described size, and it is proper to give them a little air by placing a small piece of wood under the edge of the glass, at one side. In a short time afterwards the glass may be entirely removed. (Hort. Trans. iii. 338.)

769. The seeds come up in from two to three months, and the plants flower the following year. It is not known how long these seeds retain their vegetative quality, but two plants of acrostichum calomelanos were raised from seeds brushed from a specimen of that fern in the herbarium of Foster, supposed to be near fifty years old. But the same success did not attend similar attempts with any other species from different families of herbs; the soil for ferns should be of a suit description from that of the small fibres of the roots; it requires also to be kept constantly moist in imitation of the native habitations of these plants; which is generally under the shade of trees or rocks. Hence also they may be set in dark parts of the stoves where nothing else will thrive.
MONTHLY FLORICULTURAL PRODUCTIONS.

SECT. IX.

Selection of Dry and Bark-stove Plants, for such as have only one hot-house to contain them.

WOODY PLANTS.

Bambara arundinacea, Bitteringia speciosa, Carica papaya, Castor oil plant, Cleome spinosae, Coccoloba ussuriensis, Corchorus capsularis, Corypha umbraculifera, Cuchia hystrix, Cuscuta pulchra, Datura arborescens, Dillenia speciosa, Dracaena draco, Ficus indica, Hibiscus rosa-sinensis, Lora coccinea, Lagernstroemia reginae, Minsoa nobilis, Osidanta, Pteroclymenum, Pyrus myrtillus, Nerium coronarium, odorum, Nyctanthes arbor-tristis, Pimenta polyantha, Robinia pseudoacacia, Sambuus nigra, Sterculia pinnata, Tectona grandis, Virosa rosea, Velutina aculeata.

FLOWER-GARDEN.

The crocus, tulip, and some alliums, beginning to emerge from the ground. If mild weather, perhaps some choice plant in flower, as the Christmas rose, daisy*, but generally no flower is to be seen this season.

The snowdrop*, Christmas rose*, and winter aconite* in flower; the crocus, Corydalis, and other bulbs, fast advancing, if the weather be favorable.

Among florists' flowers, the crocus, scilla*, some hyacinths*, crown-imperial*, and also the prionum*, and polyanthus are in bloom in the latter half of the month; saxifrages oppositifolius among the alpines; and viola odorata* in a warm border, or on rock-work.

The hyacinths*, narcissus*, anemones*, and polyanthus are in great perfection in the latter part of the month. The rose, among the best valued floral flowers are in perfection in the course of this month. Also, the scilla, fruticata*, wallflower*, daisy*, pulmonaria officinalis, cynthia, Veronica, various saxifrages, and other alpines.

Some pines, peatitlars, and willows*, show their catkins; the sloe*, cornelian cherry*, meacontown* different varieties, daphne poncea and collina, the lonicera nigra*, and rosemary in flower. The ring-dove begins to coo in the first week.

Most of the wild fruit-trees, as crabs*, pear*, cherry*, and their allied species, are now in flower: most of the willows, birches, elms, and oaks, their catkins. Among shrubs, the honeysuckle, some robinias*, ammobiums*, daphne, ericas*, and zanthorrhiza, are in flower.

The horse-chestnut*, hawthorn*, sorbus*, magnolias*, and snowdrop-tree*, in great beauty. Among the American shrubs, several species of magnolias*, azaleas*, Lilacias, and metrosayas*, &c., and among common shrubs, the lilac*, privet*, buckthorn*, honeysuckle*, the cinnamon, Scotch, barberry, not-leaved, and monthly roses. Most of the singing birds in full note.

In the green-house, above thirty species of azaleas*, many of the finest, as many as the family, with lachanias*, oxalis*, and various other genera in perfection.

In the pine, dracaena*, bromelia*, kumferp*, and various other genera in flower. Abundance of forced articles, included annually, as sweet peas, larkspurs, etc., in flower.

In the green-house, above thirty species of azaleas*, many of the finest, as many as the family, with lachanias*, oxalis*, and various other genera in perfection.

In the pine, dracaena*, bromelia*, kumferp*, and various other genera in flower. Abundance of forced articles, included annually, as sweet peas, larkspurs, etc., in flower.

### FLOWER-GARDEN.

The collections of paeonies and anemones not yet faded; those of ranunculus* and tussilago*; phlox, and of the hardy gladioli* and irises, in full beauty. Arrangements of many of the sweetwilliams*, in flower, towards the end of the month; biennials, such as aquilegia*, campanula*, veronica*, and many showy herba- ceous perennials; some biennials, as agapanthus, alium*, &c., annuals; as crocuses, cacti; aquatics; as butomus*, hydrocharis, potamogeton; vias, anagorgia*, and various alpines.

The florists' flowers of this month are, the pink*, and carnations; the white marguerite*, daisy, and tigger lilies; the Brompton stock*, larkspur*, lupines, and other biennials and annuals. More herbaaceous plants are now in flower than in any other month, as chelone*, delphinium*, bellflowers, persicaria, etc., and some other perennial flowers. The tulip-tree*, or paulownia, (Paulownia tomentosa), and some other of its species, are now in flower, and various alpines.

The florists' flowers of this month are, the hollyhock*, pyramid bell-flowers*, lobelias, annual stocks*, and the poppies*, with lilium canadense* and four other American bulbs. Narcissus flowers. Many herbaceous plants are now in flower that first appear in July, and continue as aster, astilbas, heucheras, authenticums, oualum, and numerous others first bloom in this month. Among the aquatics may be mentioned pelargoniums, pelargoniums dalmaticum, pelargoniums hybridum, and several species of potamogeton.

The florists' flowers of this month are, the dahlia*, clematis, carnations, and chrysanthemums. Although by artificial heat previously planted in the open ground in July and August, the bulbs are not much injured in this way, it is now in perfection. Among the flowers there are only few autumnal narcissus autunnumus, narcissus autunnumus, and scilla autumnale, and some chrysanthemums in all its varieties, is now in perfection. Among the herbaceous perennials, there are asters, sedums, gentianas, phlox*, and asphodelus, are the chief sorts.

The florists' flowers of this month are, the Chinese chrysanthemum*, some of the hardier of which will now flower in the open air, and others under a glass case or in the greenhouse; the colchicum*, autumn crocus, cyrtogonum europeurnis, and amaryllis lutea*. The principal herbaceous plants are, asters, sedums, gentianas, phlox*, and asphodelus, also with alliums albulum*, heucheras, gentianas*, and some other genera.

The remains of last month in greater or less beauty, according to the weather. Clematis has also been destroyed by the cold, and has been in bloom. The remains of last month, according to the weather. Clematis has also been destroyed by the cold, and has been in bloom.

### SHRUBBERY.

The time, laburnum, and fringe-trees*, in flower; towards the middle of the month a number of the roses of Americans* andromeda, monarda, rhododendrons maximum and peric- tum, azaleas, &c. Of Common shrubs, choisus, hollanchem, erica, dog-wood, elder, cythian, spirea, lonicera, &c. The goat-sucker, or fern-owl (Capni- smia europeurnis), heard in the evening of the first week, singing birds leave off singing about the end of the month.

The tulip-tree*, magnolia*, kalium*, andromeda*, azaleas*, ericas*, several sorts, and some rhododendrons*, and other American or peat-earth shrubs in flower. Among the common sorts, the roses are now in full perfection. The white jasmine*, honeysuckles*, clematis*, spartium, gleditschia tricangulata, choisus, lonicera, and a great variety of others of less note. Showy butterflies and moths appear in the beginning, and the dragon-flies towards the end of the month.

### AUGUST.

Scarce any trees are now in bloom; but of the old species there are various sorts of azaleas, fleurets*, and magnolias, in perfection; and of select common shrubs, which, with its numerous and beautiful variety, is now in perfection. The roses, the honeysuckle*, yellow jasmine*, clematis*, spartia*, and dwarf chrysanthemums, show in the shrubbery and roseary in many other month. Robin-red-breast (Montesilla rubicola) sings about the last week, and butterflies, moths, and dragon-flies abound during the whole month.

The green-house is as before. In the open air, the plants growing vigorously, but excepting geranium*, ericas*, and some succulents not many species in flower. In the store, officinalis, convolvulus, panthea, gynura, pascalium*; plumago, and numerous other hardy flowering plants. Tender annuals supplied from the reserve-greenhouses as before.

### SEPTEMBER.

Aralia spinosa, some azaleas*, and kalium*, Lord Macartney's delphinium, and one or two other roses are in flower during this month. But the chief ornament of the shrub-bery is the multitude of the monte-blooms, virginianus, nigilipus*, oxycahnthas*, Siberian crane*, sorts*, lonicera*, apple, rose, elder, &c.

There are not many store plants in flower at this season; amaryllis*, pot-silvers, and some succulents may be mentioned. Tender annuals supplied from the foreign-department, for the greenhouse, for decorating the plant-cab- inet, conservatory, or drawing-room.

### OCTOBER.

Arbutus unedo* is the only beautiful shrub in flower, and also in fruit, at this season, gardenia, rhododendrons, barberry, ericas, clematis, and the common ivy are also in flower.

The green-house plants generally return to their winter habitation in course of this month; some heaths*, and pelargoniums*, and a few other species in flower.

Any spare room in the green-house is now occupied with chrysanthemums*, and some dahlias* raised in pots, and placed out of the reach of frost, to prolong their bloom. A few ericas*, statice*, and geraniums, still in bloom.

The green-house is as before. In the open air, the plants growing vigorously, but excepting geranium*, ericas*, and some succulents not many species in flower.

### NOVEMBER AND DECEMBER.

Dryandra*, ericas*, lantanas*, and cas- melia*, about the middle of the month, in the green-house. In the store, all the species of stre- lithium, alani stellaps*, amaryllis*, aletris*, and one or two others.

From the forcing-department, hya- cynth*, Persian iris*, and other bulbs, monthly roses, and, last Christmas, the Provence roses*, and other shrubs and flowers, up to 5 feet high, in pots.

The pith filled with tender annuals, or other plants, in the course of propagation and rearing.

### HOT-HOUSE DEPARTMENT.

In the green-house, chiefly tender an- nuals from the reserve-garden; the proper inhabitants being in the open garden, and there the heats, gera- nium, citrus tribe, discom, crass, senecio, &c. In great beauty.

In the store, aster* sibiricus, and other bulbs, aloes, piper, and other succulents; eugenia, epipremnum, caudas, &c. and in great beauty.

In the store, areEEs* sibiricus, and other bulbs, aloes, piper, and other succulents; eugenia, epipremnum, caudas, &c. and in great beauty.

The reserve hot-houses as before.
BOOK III. ARBORICULTURE, OR PLANTING.

6742. A tree is an object which has at all periods been held in a certain degree of admiration by mankind, from its grandeur, its beauty, and its use: a few trees have accordingly been associated with the dwellings of civilised nations in every country. The Persians, Greeks, and Romans were particularly attached to trees: some of their greatest men were proud to acknowledge that they had made plantations with their own hands; and fine specimens, whether planted by nature or art, were held sacred, or specially protected. (37.) The Romans, besides the ornamental plantations of their villas, planted occasionally for useful purposes; they had live hedges, osier plantations, and rows of poplars and elms as props for their vines. (57.) The planting of extensive tracts for timber or fuel, however, does not appear to have been practised by them, or any other people, till the beginning of the sixteenth century, when the insufficiency of the natural forests, which had hitherto supplied civilised society in England with timber and fuel, rendered planting a matter of necessity and profit. In the century succeeding, the improved practice of agriculture created a demand for hedges and strips for shelter; and the fashion of removing from castles in towns and villages, to isolated dwellings surrounded by verdant scenery, led to the extensive employment of trees both as objects of distinction and value. For these combined purposes planting is now universally practised: what relates to the effect of plantations, as parts of rural scenery, belongs to landscape-gardening; and what relates to their use and culture is the subject at present under consideration. We must however keep both objects in view, as well in contriving what shall be most profitable, as in designing what shall be most ornamental or picturesque. We shall therefore consider the uses of trees and plantations with a view both to profit and ornament; the kinds of plantations, their formation, their management, the formation of a tree-nursery, the surveying and valuing of trees and plantations, and the catalogue of timber-trees and hedge plants.

CHAP. I.

Of the Uses of Trees and Plantations, and the Profits attending their Culture.

6743. The purposes for which plantations are made, may be reduced to those which respect the actual consumption or employment of the tree or shrub individually; and those which respect their collective influence relative to surrounding objects. The first considers trees as affording timber, fuel, bark, and other products; and the second views plantations of trees as affording shelter, shade, fences, ornament, or otherwise conferring value on territory.

SECT. I. Of the Uses of Trees individually, as Objects of Consumption.

6744. A tree is employed after it has attained a certain age, bulk, or dimension, either in civil, military, or naval architecture; in the construction of machines, implements, and utensils; as fuel; or as affording tannin or dyeing matter; food or medicine for men or animals; or poison for vermin.

6745. For civil architecture the natural timber of the pine and fir tribes is in greatest demand, and foreign deal is generally preferred to British produce, as being of larger growth, and more resinous and durable in quality and texture. That which approaches the nearest to the pine and fir timber of the north is the Scotch pine (Pinus sylvestris), when grown in the north highlands, and the larch fir (Pinus larix), when grown in hilly or poor districts; resinous timber of the species indigenous in cold countries, when grown on rich soils, and in warm climates, being found deficient in durability. Oak and elm are also used in buildings, especially the former, as being of great durability and suitable for wooden bridges, breakwaters, joists in damp situations or on ground-floors, sills, wall-plates, staircases, door and window frames, sashes, &c. Elm is not much used in buildings of magnitude, as being apt to twist, and not very durable; but it makes curiously variegated floors and steps of stairs, and very good weather-boarding for sheds and agricultural buildings. Besides timber and timber-like trees for the general purposes of civil architecture, there are some departments of rural construction, as the formation of fences, drains, embankments, trellis-work, arbors, and the supporting of plants in gardens, which consume branches, spray, thinnings of young plantations, and shoots even of a year's growth. Almost any species of tree may be used for these purposes; but the branches and spray of the oak, elm, and beech, the weodings of ash or larch plantations, the shoots of a few years' growth of the oak, sweet chestnut, ash, and hazel, and of one year's growth of certain species of willow are greatly preferred.

6746. For military architecture, by which we mean chiefly the outworks of fortifications, any tree is taken; but the pine and fir tribes are greatly preferred, as requiring less labor in cutting and preparing. Besides those of a timber size for constructing bridges, portals, and others of less dimensions for palisadoes, chevaux de frise, &c.; branches, spray, and shoots are used for fascines, and fixed works en haies, en corbeille, &c.

6747. In naval architecture the oak is chiefly used. According to Marshall, "the keels are now prey generally laid with elm or beech; and part of the upper decks of
men of war is deal: but these woods bear no proportion, in respect of the quantity used, to the oak. The timbers of a ship are principally crooked, but the planking is cut out of straight pieces. In a seventy-four gun ship, the crooked and straight pieces used are nearly equal, but the planking under water is of foreign oak: therefore, of English oak, the proportion of crooked to straight pieces is almost two to one. Masts and yards are of deal. The blockmakers use elm, lignum vitae, box, and other hard woods. Upon the whole, it may be said, that, in the construction of a ship, oak is the only English wood made use of; and that of this English oak nearly two thirds are requisite to be more or less crooked."

(Planting and Rural Ornament, i. 49.)

6748. In the construction of merchant-vessels, Montath, in 1820, states, that "the out-kiel commonly used is of beech or elm, and made generally of two or three trees or pieces joined together to whatever length is required; these require to be nearly straight. The keel-stone, or inner keel, requires trees of nearly the same description, but chiefly oak, or sometimes pine. Floor and frames used are of a good deal crooked. First class vessels have a good deal crooked towards the one end, as they begin to ascend up the vessel, and are more valuable than the floor timbers, but are also used sometimes of elm and beech. Upright timbers are always made of oak, and are considerably crooked, for elm or beech is seldom put into a good vessel, except the lower part, where the vessel is always under water when light. Top timbers are also of oak, but not so valuable, as they are mostly straight. Beams go under the deck of the vessel, and are also all oak, and have but a small crook, but require trees of considerable length. Knees are always of oak, and are the most principal crooks in the vessel. The stem-piece is a very particular crook. Breast-hooks also have particular crooks. Stern-posts and windlass are straight pieces. Trees that will cut up for planking are used of a great length as they can be got, and are the better for having a considerable crook or curve one way; these are used of elm or beech for planking under water, but for the floors required for oak for this purpose, or elm or beech."

6749. Straight timber is bent to any form by the use of steam, and other improvements in ship-building; and thus the larch or any sound resinous timber may be employed, and is so to a certain extent for commercial ships. Sir A. Grant, an experienced planter, is of opinion, that "the larch will, in the course of 50 years, be as useful in ship-building as British oak."

6750. In a communication to the President of the Board of Agriculture, by Wilson, of London, dated in 1739, the idea is suggested of combining small timbers for all the purposes of shipbuilding. He suggests, that oak of only thirty-three years' growth may be made fit for this use; and that "a hundred barrels made from British timber, have a hundred barrels made from foreign timber, and are less liable to accident." The use of timber of small growth has been already introduced in the construction of masts for the largest vessels, either by splicing pieces properly adapted together, or, by forming hollow masts from small timber, which, uniting strength with lightness, have advantages which solid ones do not possess. (Ferring and Money on Ship-building.)

6751. In the construction of machines, the millwright's chief material is oak, beech, and crab-tree for cogs; alder, and sometimes willow, for float-boards; and fir and oak for shafts and frame-work. The waggon and cartwright uses oak and ash for bodies, axles, and spokes; elm for naves, fellies, and linings; sometimes also the softer woods for linings, as poplar, willow, lime, and horse-chestnut. The coachmaker and ploughwright use more ash than any other sort of timber. Gates are made of oak and deal, and their posts of oak or larch; the soft woods are sometimes used, but are far from being durable. Ladders are formed chiefly of deal, or of poplar and willow, as being light; pumps and water-pipes generally of elm and alder; beech and sycamore are used in making calenders and cheese-presses, &c. For all these purposes the timber must be full-grown, with some exceptions, as young or root-cut oak and ash for spokes and shafts.

6752. In implements, root-cut ash is in general use for the handles of such as require to bear great stress, as of the spade, fork, mattock, forge-hammers, &c.; willow or deal, of the lighter tools, as the hoe, rake, scythe; beech and sycamore for the common tools and instruments of carpenters; box, holly, elder, &c. for the more select tools of artisans, and for mathematical and gaugers' instruments.

6753. For utensils, under which is included household furniture, the chief British wood used by the cabinet-maker is beech for bed-frames, chairs, and sofas; next, birch and beech-leaved elm for the same purposes; oak for gothic furniture; the cherry, plum, holly, yew, box, walnut, lime, poplar, and a great variety of woods for occasional purposes; and deal cutters more or less into the construction of almost every type of house. The most important cabinet-maker uses lime, box, yew, holly, plum-tree, and poplar.

The carver uses chiefly lime, and next, pine deal; the cooper uses oak, and some chestnut for large vessels and vessels, corn-measures, &c.; birch and alder for herring-barrel staves, sycamore for herring-barrel corks, and fir for those used to be put into fire-places. Fir or firrings, as they are called, have been in great demand (Montath); ash for dairy utensils, butcher-firkins, flour-barrels, &c.; oak for well-buckets and water-pails, and, in some places, for milk-pails and other dairy utensils; beech is occasionally used for the same purpose, and for soap-firkins, and willow, ash, and elm are used for hoes. Beech and sycamore are used beech, sycamore, beech, box, and holly; trunk and packing-case makers, deal, and whatever sorts may be cheapest at the time; coffin-makers use chiefly elm, sometimes oak; basket-makers the root-shools of the willow, and sometimes of the hazel; bee-hive and straw utensil makers use the bramble and willow; besom-makers the spray of the birch, broom, heath, lath and patten makers, alder and birch; the toy-maker, lime, and other soft woods, and also box, holly, and some others. For most of these purposes, the trees must have attained a timber size, and for some of them, they should be full-grown.

6754. For fuel, any ligneous vegetable may be used at any age, and either the body or trunk and root of the plant, or its branches and spray. Resinous trees, excepting the larch, afford most flame, and may be used the soonest after being cut; the ash next in order, then the birch, whose oily bark burns clear; oak and elm burn the slowest; and the roots of trees are generally of more slow combustion than their tops. To produce fuel in a short time, the most rapid-growing tree is the common tree-acecia (Robinia
Pseudacacia). Charcoal, as fuel, is prepared by subjecting roots, or the more ligneous parts of branches, to a smothering combustion.

5754. For affording the tannin principle, the bark of the oak is chiefly used; but that of the Huntingdon willow (Salix alba), larch, black poplar, birch, chestnut, hazel, thorn, and some other trees, is found to afford it in such quantities as renders it worth while to disband them for that purpose. (Agr. Chem. 89, and Com. to Board of Agr.) The bark is most powerful when taken from the tree at an early age, and having the bark is cut down before it attains a timber size, for that purpose, as in copeo-woods; but the bark of old trees is also used.

5755. For dyeing, the bark of several trees was formerly in use, as of the crab-apple, pear, ash, alder, &c. The bark of the extinguish (Quercus tinctoria) is used for dyeing yellow in North America; but in this country, foreign materials, as indigo, logwood, madder, &c. have superseded the use of indigenous, or home-grown vegetables. The berries of some trees, as of the elder, and berry-bearing alder; and the leaves of others, as of the walnut and sloe, have also been used as dyestuffs. In various arts and manufactures some of the products of trees are used, as the charcoal (of the dogwood principally) in that of gunpowder; the pitch of the pine, the resin of the spruce fir, and the turpentine of the larch, for a great variety of purposes. The ashes of the burnt branches of all trees, but especially of the elder, alder for the laundress's use affords, on distillation, the pyrrolineous acid, an excellent preservative of timber, and, when purified, a substitute for salt in preserving butcher-meat; the bark of the holly affords birdlime; and the leaves of all trees, excepting the resinous kinds, rot into excellent manure for the field, and highly prized vegetable mould for gardens.

5751. For food to man, in his present state, the timber-trees afford but little resource; but nuts of the sweet chestnut, walnut, and hazel are still esteemed, and our ancestors used the acorn, beech-mast, haw, roan, hip, and Bramble. A very agreeable drink is made from the sap of the birch-tree in Sweden, Russia, and some parts of Britain; and, in America, sugar is obtained from the sugar-maple (Acer sacchararium) in sufficient quantities to be used in domestic economy. Mast and acorns are esteemed excellent food for swine, haws for deer, and the leaves and spray of many sorts of trees are, or may be, eaten during winter by domestic and wild animals, as in every cultivated country, which, one of the most evident luxuries of the table, is localised by plantations, in which both birds and quadrupeds find at once shelter, security from their enemies, and food.

5752. For medicine; the products of scarcely any British tree is in use; but the bark, blossoms, and berries of the elder; the fruit of the sloe and crab, and the leaves of the walnut were formerly in considerable repute, and are occasionally used.

5753. As poisons for vermin, the leaves of the walnut, elder, and ash are used by infusion for destroying the rather annoying worms by their bitter acrid quality; a glutinous snare for entrapping birds is obtained from the holly and mistletoe.

5754. General result. From the above outline it may be inferred, that the timber-trees in most general demand are, oak, ash, beech, chestnut, hazel, and poplar; for shade, and ornament, &c. In the greater number of cases, casters parvus, the oak, larch, Scotch pine, ash, beale, poplar, and willow, will be found the most profitable trees that can be planted with a view to timber or bark produce.

SECT. II. Of the Uses of Trees collectively as Plantations.

5761. Trees collectively in a growing state may be useful by affording shelter and improving the local climate, improving bad soils, producing shade, by separation, seclusion, distinction, appropriation, concealment of disagreeable objects, heightening the effect of agreeable objects, creating beauty, and adding value prospectively.

5762. Shelter and climate. The umbrageous roof of the forest afforded shelter, and a secure retreat to our savage forefathers; and their civilised descendants still resort to the nearest tree as a place of shelter during a casual storm; to the thick forest as a place of security, when they set the laws of their country at defiance, or have committed crime. Considered agriculturally, "the advantages to be derived from subdividing extensive tracts of barren country by plantations, are evidently great, whether considered in the light of affording immediate shelter to the lands, or in that of improving the local climate. The fact that the climate may be thus improved, has, in very many instances, been sufficiently established. It is, indeed, astonishing how much better cattle thrive in fields even but moderately sheltered than they do in an open exposed country. In the breeding of cattle, a sheltered farm, or a sheltered corner in a farm, is a thing much prized; and, in instances where fields are taken by the season for the purpose of fattening them, those most sheltered never fail to bring the highest rents, provided the soil be equal with that of the neighboring fields which are not sheltered by trees. If we enquire into the cause, we shall find that it does not altogether depend on an early rise of grass, on account of the shelter afforded to the lands by the plantations; but, likewise, that cattle which have it in their power, in cold seasons, to indulge in the kindly shelter afforded them by the trees, feed better; because their bodies are not pierced by the keen winds of spring and autumn; neither is the tender grass destroyed by the frosty blasts of March and April." (Plact. Kol. p. 121.) In gardening, as we have already seen (2400.), shelter is not less important than in general economy.

5763. Climate. An Italian author (G. Guadieri) has enumerated and illustrated the advantages, in that of an Italian, which cut off the effects of contrary derive from extensive woods and forests. "These," he says, "are the arresting the progress of impetuous and dangerous winds; maintaining the temperature of the air; regulating the seasons; lessening intense cold; opposing the formation and increase of ice; moderating the temperature, producing abundance of rain and snow; giving origin to springs, and producing abundance of water in the rivers; discharging the electricity of the atmosphere; dispersing hail, snow, and watery clouds; preserving from inundations; lessening the width and depth of torrents; opposing a barrier to the undermining of banks, and the formation of precipices; preserving the soil on mountains, by retarding the reduction, and making it more compact; and detracting from the formation of avalanches, or accumulations of snow." He illustrates each of these propositions by references to what has taken place in Italy and Germany, in consequence of alterations that have been made in the woody surfaces of these countries. (Dello Ingeno &c. Bachi, &c, Milano, 1577.) Williams, an English author (1592.), has endeavored to show that the climate of Britain is deteriorating by the increase
of plantations. These, whether in masses or even in hedge-rows, increase the evaporating surface, and consequently render the atmosphere more humid; an open country, by so doing, would be more dry, airy, and wholesome. This is, no doubt, correct; and, perhaps, some valleys and plains are more thickly studded with hedge-rows and strips, than a strict regard to the culture of corn, or the salubrity of the atmosphere, would justify; but the same objection will not apply to elevated situations and bleak hilly tracts, which every one allows are greatly improved by planting, both in climate, agricultural produce, and general effect.

676. **Improving bad soils.** "It certainly is not one of the least recommendations of planting," observes Pontey, "that it may be made to contribute essentially to the improvement of a bad soil. Where on sterile heaths and sands is, as far as the case permits, the want of sufficient individual interest precludes all extraordinary exertion, and the country so cultivated has the same appearance now, that it had many centuries ago. Even on entire properties lying open, the want of the power of separating and classing cattle, and regulating their mode of grazing, and protecting particular fields for particular purposes, &c. is found so great a disadvantage as to be quite incompatible with the practice of improved farming.

677. The **separation** produced by ligneous vegetables, in the form of hedges, is of long use in gardening, and of great and acknowledged importance in agriculture. In the latter art it may be considered as a criterion of improved culture; for when lands are intermixed in which the cultivated is not in some way distinguished from the uncultivated, the same degree of wealth and happiness that the same property may enjoy itself in its own way.

678. The **distinction** any sort of trees afford to a dweller in a remote solitary country, or exotic species in an established, will consist in conveying cheerful and social ideas to the passing stranger, and procuring for the owner that applause for improvement which he feels to be his due. In extensive demesnes the outlines or prominent parts of them, may be indicated by particular sorts of trees; so as, from the house, or from the prospect-tower, in a central part of the estate, to render the contour of the whole distinguishable. Where common, or any one kind of trees abound, uncommon or exotic kinds may be made use of; or a common tree, pruned in a particular way, will have an adequate effect.

679. To **appropriate**, harmonise, or render properly a part of a near estate, distant woody territory which does not belong to it, may be considered as a selfish principle under the disguise of a social one; but it is, at all events, harmless in a moral point of view, and is valuable as a device in improving the beauty of real landscape. Whatever may be the kinds of trees, or the forms in which they are planted in the distant or adjoining property, which we may wish to appropriate (fig. 625 a, b); the principle is, to plant the same sorts of trees in corresponding forms (bb), in the property which we can call our own.

680. The **concurrence** of disagreeable objects by trees is too obvious, useful, and universal an improvement to require being enlarged on; this is one of the most important uses to which they are applied in small districts in a populous country, or near large towns. The desire of shutting out the houses of others, and especially of our poorer neighbors, does not so much arise from dislike either to the objects or the inhabitants, as from love of versant scenery, and from a wish to have a country-seat, as much like the country as the owner wishes. The desire of shutting out manufactured works, works-houses, &c. is still greater, because those objects excite ideas by no means in harmony with rural quiet; but no one ever thinks of shutting out a distant farm-house, solitary cottage, church, water-mill, bridge, monument, or ruin; for these are all interesting and agreeable objects, which are either charas-seistic of the place, or are so very general that they are universally consulted.
importance to the improver, whether he displays water, or erects buildings, or harmonises rocks and mountains. A country-house without trees is felt by every one to be but a part of a whole.

6772. Trees may direct the eye to objects that would otherwise escape notice, or whose beauties would be lost in a general view. By employing them in the foreground of a scene to shut out uninteresting distance or mere sky, the eye may be led to repose on some agreeable near, or interesting distant object, which it had before wandered over unnoticed. By this sort of indication, accompanied by a seat, the dome of St. Paul's at London, or St. Peter's at Rome, and the cupola of the Iwan Wilika of Moscow, are seen from the grounds of residences at twenty or thirty miles distance from these capitals; and in this way the worthy and amiable Shenstone, pointed out the Wrekin, and church-spires of Halesowen, from the rustic path of the Lessowes.

6773. Trees render indifferent objects interesting when judiciously grouped with them, so as to seem to conceal, by accident, that which we should desire or imagine to be there. Thus, a fragment of a wall, or of a tower, emerging from a thicket, may, by imagination be considered as an index to the main body of the ruined mansion or castle concealed by the wood. A broken gothic arch emerging from a thick wood may seem the commencement of a cloister or the aisles of a ruined abbey. A large stone lying on a naked surface is an object of little interest in a picturesque point of view, but surrounded by a few trees and bushes, it may be taken for part of a stratum of rock. A few yards of brick wall, standing naked and bare in a field would be considered as a deformity; partially cover it with ivy, which may first ascend and then mantle over its top, and add a holly or thorn, a briar, and an oak or ash, and a beautiful group is produced. In scenery, where great deformities or featureless extent is mixed with beauty or grandeur, trees will conceal the latter, and display the former to advantage. Ranges of naked mountains often present this kind of mixture of feature, dulness and want of grouping (fig. 655.), which no improvement but planting could ameliorate and render tolerable. Gilpin, in his Tours to the Lakes and Highlands, &c. has some excellent observations on this subject; and there are various instances in the Pentland and Grampian ranges of hills where improvements of this sort have been executed with the happiest effect. (fig. 627.)

6774. Beauty may even be created by trees independently of all other objects. A dull flat surface will be rendered more interesting by scattering a few trees over it, of any sort, and in almost any manner: but it may be grouped or massed by one, a few, or by many sorts; or laid out in avenues, stars, platoons, and other modern or ancient forms of planting, so as to become a scene of positive beauty. Every species of trees has its particular form, bulk, mode of growth, flowering, &c. which constitute its character; this character varies with the age of the tree, and its situation, relative to other trees, or to soil, climate, &c. Now, as every tree may be grouped, or combined with those of its own species, or with any or all of the others, in an endless variety of ways, the beauty that may thus be created by trees alone, can only be limited by the extent of surface on which they are to be grown.

6775. The value of landed property containing plantations is enhanced prospectively by the various properties of trees. "It is very generally known," Suhr observes, "that such estates as have a quantity of well arranged, healthy timber upon them, when brought to sale, bring an extra price, according to the quality and value of the wood, not only at the time of sale, but, counting forward on its value, to the period of its perfection. Thus, supposing the half-grown timber on an estate to be valued at ten thousand pounds at the time of the sale, instances are to be found where thirty thousand pounds have been given, over and above the valuation of the lands. The purchasers of such estates wisely foresee the increase of value which will arise from healthy timber growing, where it may not only be cherished till of full maturity, but where, probably, it can then be turned to the best advantage by reason of its local situation. But, besides the real value of grown timber, there is most generally an ideal value attached to it, namely, that of its ornamental appearance." (Plant. Kal. 124.) A landed proprietor, who is a parent, looks on a thriving plantation as capital laid out at compound interest, and on the most undoubtedly secure, for the benefit of his offspring; and he values it in this respect the more, because no man can determine the ratio in which, from the progress of the trees, and the future prosperity of the country, it may increase in value. It does not happen to many to plant trees and eat them down at a mature age; but this only renders planting a more interesting performance to the man who is in secure enjoyment of an estate; for in his full-grown trees he finds a link which connects him with his ancestors, and in his young plantations another which carries him down with his posterity to the next age. In this way he may imagine himself a being "having neither beginning of days nor end of life."
Sect. III. Of the Profits of Planting.

6776. From the seemingly distant advantages of planting has arisen the practice, by authors, of presenting statements of the profits, pleasures, and honors attending it, with a view to excite the selfish or patriotic feelings of their readers. "The profits of planting," says Marshall, "are great, when properly executed, and this idea adds solidity to the enjoyment. Pleasure alone may satiate; but profit and pleasure united seldom fail of producing a lasting gratification." Every one who has the least taste for country matters, must be alive to the agreeable and satisfactory feelings with which plantations are formed; and certainly there is something disinterested and respectable in incurring a present expense for what in most cases is to benefit a future generation; but as to the extraordinary profits, either of a near or far distant period, they are by no means to be depended on. With respect to the absolute profit to be derived from trees or plantations, considered independently, it is easy, by a calculation founded on a seemingly very moderate data, to make the clear gain attending the raising of any crop appear considerable; and, accordingly almost every speculative cultivator, whether of corn or trees, calculates on making a fortune in a very few years, as soon as he can get possession of a farm or a tract of waste. The truth is, however, that though accidental circumstances may render it more profitable to cultivate one kind of crop, either of trees or corn, at one time and place rather than another; yet, on the whole, the profits of capital employed in any way in agriculture or planting must, on the general average, be nearly the same. The certain lapse of time which must ever intervene between the planting of trees and their attaining a disposable size, must alone render any calculation made at the time of planting, extremely problematical. In planting, as in every other branch of culture, extraordinary profit is attended by extraordinary production, which soon sinks the market value of the article; add also, that in a commercial, free and highly taxed country, whenever any article attains a very high price, substitutes are found at home, or imported from abroad; so that no particular crop should be considered as exclusively the best to cultivate, and no extraordinary profits ever calculated on from any crop. Plantations should be made with a joint view to all or part of the advantages which we have shown to be attendant on them; but no more ultimate profit calculated on, from the disposal of the trees, than what is expected from capital laid out on any other territorial improvement; indeed, the safest principle on which to act, is to consider capital employed in planting, as on a par with that laid out in the purchase of landed property.

6777. With respect to the value of trees as plantations, or in masses, that is entirely relative; and must be sought for in the additional value conferred on the adjoining lands by the improvement of their climate, or their beauty. This sort of value cannot easily be subjected to any general rules of estimation; but unquestionably capital employed in planting and cultivating trees for such purposes, especially for the former, or when they are both united, may be considered as likely in the end to yield a greater interest than that employed in the ordinary routine of tree or corn culture. In bleak exposed situations, the advantages which have arisen from screen plantations have in some cases been so great as to be estimated at a third of the value of the land, and in every case where shelter is wanted they must be considerable. These, however, should be looked on by the prudent man rather in the light of extraordinary cases, attended by unforeseen risks, and though depending chiefly on skill, yet in some degree also on chance.

Chap. II.

Of the different kinds of Trees and Plantations.

6778. Having considered the different objects for which trees and plantations are cultivated, our next step shall be to arrange trees and plantations, according to their qualities, for fulfilling these objects.

Sect. I. Of the Classification of Trees relatively to their use and effect in Landscape.

6779. Timber is the grand object for which trees are cultivated, and it is either straight or crooked in form, large or small in dimension, hard, soft, or resinous in quality, brittle or flexible in texture, smooth or rough grained, and plain-colored or variegated in appearance.

6780. Straight timber is chiefly produced by the pine and fir tribes, and such other trees whose lateral branches do not generally acquire a timber size, as the Lombardy poplar, hornbeam, deciduous cypress.

6781. Crooked timber may be produced by any branching tree; but chiefly by the oak, sweet chestnut, broad-leaved elm, walnut, &c.

6782. Timber of large dimension, in regard to length, is produced by the spruce fir, larch, Lombardy poplar, as, narrow-leaved elm; in regard to diameter by the oak, sweet chestnut, and elm; magnitude in both dimensions is unitcd in the narrow-leaved elm, beech, oak, and larch fir.

6783. Timber of small dimensions is produced by the yew, holly, thorn, ash, maple, laburnum, &c.

6784. Timbers, hard in quality, or, what are called the hard woods, are the oak, chestnut, sycamore, ash, beech, plane, walnut, box, holly, yew, &c. Softer timbers, or the soft woods, are the poplar, willow, lime,
The smooth-grained, oak, but and avoid, and, also the ten horse-chestnut. That which affords it in greatest quantity is the oak; and next, as far as chemists have yet ascertained, the Leicester willow (Salix alba, var.), Spanish chestnut, ash, sloe, Lombardy poplar, hazel, elm, common willow, sycamore, beech, horse-chestnut, birch, and larch. (659. & Agr. Chem. 89.)

Charcoal, which is made from either branches, trunk, or roots, has been afforded by different trees at the following rates per cent.; laburnum, 24;5; chestnut, 22;2; oak, 20;6; walnut, 20;6; holly, beech, maple, 199; elm, 193; Norway pine, 192; sallow, 184; ash, 179; birch, 174; Scotch pine, 104. (Agr. Chem. 69.)

Ages have been afforded by the oak at the rate of 15; elm, 39; beech, 12; and poplar, 7 parts in ten thousand. (Agr. Chem. 113.) The result of Saussure's experiments, on procuring ashes from trees, have been already related. (703.)

For fuel and fencing. The tendency of trees to produce lateral branches, and renew them when lopped off, is an important quality, and exists in an eminent degree in the ash, elm, oak, willow, poplar, lime, &c.; but not at all in the pine and fir tribes, and but slightly in the plane, walnut, and some others. Those which grow most rapidly are also to be desired as fuel-trees, as the acacia, poplar, willow, in most soils; and the larch, fir, Scotch pine, and birch, on such as are dry. The althianus glandulosus may also be mentioned as a bulky and rapid-growing tree. On the chalky hills at Mereville (before the revolution one of the most extensive parks and magnificent seats in France), this tree thrives, and attains a considerable size, where few others will grow.

For hoops, basket-scales, besom-spray, implement-handles, poles, &c. the renewal of trees or shrubs which have been cut down, or trenched for fire, is of the highest importance. One of the best trees for this purpose is the oak, which is found through the greatest portion of the country. (608.)

Ashes have been afforded by the oak at the rate of 15; elm, 39; beech, 12; and poplar, 7 parts in ten thousand. (Agr. Chem. 113.) The result of Saussure's experiments, on procuring ashes from trees, have been already related. (703.)

For shelter, rapid-growing and evergreen trees are desirable, as the Scotch pine; and such as are at the same time clothed with branches from the ground upwards, as the spruce fir; the best of all trees for shelter, unless the situation is very elevated. Among the deciduous trees, the fast-growing branchy sorts are most desirable, as the larch, birch, poplar, willow; in very elevated situations, the birch, mountain ash, and Scotch fir; exposed to the sea-breeze, the elder and sycamore. To maintain a branchy leafy screen from the ground upwards, intermix trees and shrubs which stole; or such as grow under the shade and drip of others, as the holly, hazel, dogwood, box, yew, &c. To produce shelter, and yet admit of the growth of grass below the trees, prune any sort to single stems, and use chiefly deciduous sorts.

For shade, close plantations are seldom desirable, a free circulation of air being necessary to coolness; therefore use trees with lofty stems and large heads, and prune them to single stems a certain height, as the oak, elm, chestnut, beech, or spruce fir; the plane, lime, &c. for a lighter shade; the birch, beech, alder, fir, and lime, for an intermediate shade; and the walnut, elder, and laburnum, the atmosphere under which is reckoned deleterious. (703.)

For improving bad soils, and for all the purposes of planting, the soil and situation, affected by nature and tillage, is an important study for the plants. Scotch are aquatics, or delight in moist situations near water, as most of the willow and poplar tribes, the alder and elder; others are mountain trees, as the Scotch pine, larch fir, mountain ash, sors; some delight in valleys or plains, as the narrow-leaved elm, horse-chestnut, plane, lime, oak; others, in craggy steeps and hills, as the ash, silver and spruce firs, most of the pines, and many more; some on chalky soils, as the beech; others on clays, as the oak; on sand, as the Scotch pine; and a few trees will grow in the most opposite situations and soils, as the elder, which is found on mountain tops and on the sea-shore; the birch on the highest mountains, on dry rocks, and on marshes. For the poorest soils, whether high or low, choose the birch, larch, and Scotch pine; and for the richest, the asb, elm, oak, chestnuts, limes, poplars, and willows.

For the purposes of the separation of, or defence from, the inferior animals, the plantations called hedges, or close rows of shrubs, are adopted. When these are to be low, such shrubs as send out numerous branches, and so interlace one another, are the best; and, when great durability, are most desirable; as the holly among evergreens; and the hawthorn, sloe, crab, beech, buckthorn, and hornbeam, among deciduous sorts. For moist situations, the alder, elder, birch, and willow, are to be preferred; and for dry upland sites, the juniper, witch, birch, and elder; avoid poisonous trees, as the yew. For tall or tree hedges, such trees as the elm, beech, hornbeam, lime, birch, and spruce fir, are desirable; but the holly excels all other plants for a hedge, whether low or tall, and is liable to no other objection than its slow growth, which occasions a considerable expense in protecting it till it is able to serve for the purpose. (697.)

For secession and concealment, branchy leafy trees, a number of which have been mentioned (697.), are obviously desirable; and, for distinction, either sorts different from what are already there, or ordinary sorts pruned and made to assume extraordinary forms.

For the various purposes of ornament, beauty, or effect, in landscapes, the hardy trees may be arranged as to magnitude, form, mode of growth, duration, and expression.

Magnitude. Trees of great height are, the English elm, ash, larch, Polish and Carolina poplars, &c.; but the laburnum, mountain ash, and evergreen oak, are very low trees. A medium in height may be found in the maple, pine, and birch. Some trees exceed in breadth, as the oak, Spanish chestnut, and Scotch elm; others of different heights are very slender, as the Lombardy poplar, cypress, and bird-cherry.
PRACTICE with open trailers, still but others, the others, the others, as oak, near poplar and cypress, and most poplar, cypress, and most willows, have long narrow shapes, and oblong tops.

6798. Color. The Scotch pine, yew, and horse-chestnut, are dark-green; the larch and elm, a yellow-green; the alebe, Huntingdon willow, a silvery-green, &c.

6799. Mode and time of growth. The nature of some trees is to lose their lower branches as they increase in height, as the fir tribe; and others have a tendency to retain them, as the witch elm. In some the branches descend, and often recline on the ground, as the lime-tree and platanus. Some are very compact in their foliage, as the horse-chestnut; others very open, as the ash and acacia. Some have drooping spray, as the weeping-willow; that of others tend upwards, as in the Lombardy poplar; horizontally, as in the oak; and obliquely, as in the Scotch pine. Some grow with rapidity, as the Carolina and Athenian poplars; others very slowly, as the oak and the stone pine.

6800. Duration. The most durable of trees is the oak; the least so, some of the poplar and f urge tribes. A medium is to be found in the elm and lime.

6801. Expression. Some trees convey ideas of utility in the arts, and mark the attention and industry of man, as having planted them for this purpose, as the oak, ash, elm, &c. Others are known, or supposed to be of little use, and convey ideas of neglect or of wildness, as the hornbeam, sors, trembling poplar, &c. Some indicate general improvement and artificial plantations, as the larch, and spruce fir; others, garden-scenery or plantations near a house, as the cedar, stone pine, and platanus. Some indicate rich deep soil, as the oak; and rich thin soil, as the elm; others, chalk or gravel, as the beech; rocky ground, as the ash; marshy ground, as the alder; the proximity of water, as the willow. There are also natural expressions belonging to trees, partly from general, and partly from accidental situation; as strength and stability to the oak, ease and elegance to the birch, sweetness to the lime, gloom to the cypress and yew, melancholy to the weeping-willow, &c.

6802. The common hardy shrubs may be similarly arranged; but it will be sufficient to class them according to magnitude, mode of growth, evergreen, deciduous, native, naturalised, and exotic.

6803. Magnitude. Some shrubs are high, approaching to the character of trees, as the meallus and common holly; others very low, as the butcher’s broom and dwarf-birch.

6804. Mode of growth. Some are upright, as the ivy; climbers, as the virgin’s tower; trailers, as the Bramble; compact forms, as that of the arbor vitae; open airy branches, as in the tamarisk; and singular branches, as those of the stag-horn sumach. Some, as shrubs, soon acquire picturesque shapes, as the thorn, holly, and elder. Some are evergreens, as the holly, laurel, yew, laurustinus, arbutus, &c.

6805. Deciduous, as the guelder rose, lilac, syringa, &c.

6806. Native, as the holly, privet, hazel, thorn, briar, &c.

6807. Naturalised, as the rose, syringa, lilac, laburnum, &c.

6808. Exotic, or foreign, as the rhododendron, azalea, &c.

6809. These arrangements as to the effect of trees and shrubs in landscape, as far as form, magnitude, mode of growth, and expression are concerned, refer to plants growing detached from other trees, and as nearly full-grown. It is less intended to comprehend every characteristic distinction than to suggest to the artist the principal light in which he ought to view trees and shrubs. Nor could he with confidence attempt planting, with even such a knowledge as could be obtained from the above arrangement, completed by inserting all the names under their proper heads; for unless he has seen the majority of the full-grown trees himself, both singly and connected in groups and masses, and is acquainted with the comparative extent of their growth in different climates and soils, he cannot well foresee the result of his labors, or look forward with the prophet eye of taste to certain beauty. Of this there are numerous proofs, arising from the unjust preference given to objects of unknown shape and duration, in situations where the general form and situation of the tree, or even of one or two trees, is of the utmost consequence to the effect of a whole. How frequently on a lawn, or in a plantation near a house, do we see acacias, cut-leaved elders, variegated sycamores, &c. where the oak, cedar, beech, lime, or Spanish chestnut would have produced a much more impressive general effect!

Sect. II. Of the Classification of Plantations, or Assemblies of Trees.

6810. Assemblies of trees, whether natural or artificial, differ in extent, outline, disposition of the trees, and kind of tree.

6811. In regard to extent, the least is a group (fig. 628. a and b), which must consist at least of two plants indiscriminately, as a thicket (c); round and compact, it is called a clump (a); still larger, a mass; and all above a mass is denominated a wood or forest, and characterised by comparative degrees of largeness. The term wood may be applied to a large assemblage of trees, either natural or artificial; forest, exclusively to the most extensive or natural assemblages.

6812. With respect to the outline, or ground-plan of a plantation, the simplest disposition is that of a row or line, which may be either straight or crooked, as in hedges, or lines of trees; next that of any determinable shape, as round, exemplified in the clump; square, in the plateau; oblong, in either clump or plateau, and in stripes, screens, or belts; irregular or indeterminate, in thickets, masses, and all larger plantations.

6813. With respect to the disposition of the trees within the plantation, they may be placed regularly in rows, squares, parallelograms, or quincunx; irregularly in the manner of groups; without under-growths, as in groves (fig. 629. a, b); with under-growths, as in woods (c); all under-growths, as in copse
943. Or they may form avenues (fig. 630. a); double avenues (b); avenues intersecting in the manner of a Greek cross (c); of a martyr’s cross (d); of a star (e); or of a cross patée, or duck’s foot (patée d’oise) (f).

They may form regular glades (fig. 631. a, b); or irregular glades (c); glades, as niches or cabinets (d); as open squares; glades, as squares, en berceau (e); or as squares, en salons and en alleé (f).

6814. With respect to the character of tree-plantations, they may be as various as there are species; but for general effect and designation, woody plants are classed as large or small, trees or undergrowths, deciduous or evergreen, round-headed or spiry-topped; and plantations of every form and disposition may be planted with these, either separately or mixed. Thus we have groups of shrubs, groups of high and low growths, and of trees; plantations of round-headed and spiry-topped trees mixed; of trees and undergrowths; or of low growths only, as in copsé-woods and osier-plantations.

CHAP. III.

Of the Formation of Plantations, in which Utility is the principal Object.

6815. The formation of useful plantations embraces the situation, soil, form, species of tree, fencing, and other considerations.

6816. A sheltered situation and deep rich soil would be the most proper if the object of the planter was to obtain the greatest bulk of timber in the shortest time; but this would not be profitable planting, for such a soil would, in all probability, have made greater returns under common farming. The profits of planting do not depend on the absolute quantity of timber produced, but on that quantity relatively to the value of the soil for agricultural purposes. Such situations and soils as can be profitably subjected to aration or permanent pasture, will rarely be found to yield an equal profit, if planted with trees. Suppose a piece of ground to let at 60. per acre; then, in order to return the rent, and 5. per cent. for the money expended, it ought to yield 30. a year; but as the returns are not yearly, but say at the end of every fifteen years, when the whole may be cut down as copsé, then the amount of 30. per annum, at 5. per cent. compound interest, being 322. 8s. every fall of copsé made at the interval of fifteen years, ought to produce that sum per acre clear of all expenses. Hence, with a view to profit from the fall of timber or copsé-wood, no situation capable of much agricultural improvement should be planted, unless a certain part with a view to sheltering the rest; or for the purposes of separation and fencing.
6817. Whatever may be the nature of the soil, the sub-soil ought to be rendered dry if the plants are intended to thrive. Large open drains may be used, where the ground is not to undergo much preparation; but where it is to be followed or trenched, under-drains become requisite. It is true, these will in time be choked up by the roots of the trees; but by that period, as no more culture will be requisite, they may be opened, and left open. Many situations, as steep sides of hills and rocky irregular surfaces, do not admit of preparing the soil by commination previously to planting; but wherever that can be done, either by trenching, digging, or a year's subjection to the plough, it will be found amply to repay the trouble. This is more especially requisite for strips for shelter or hedge-rows, as the quick growth of the plants in these cases is a matter of the utmost consequence. The general mode of planting hedges by the side of an open drain, renders preparation for them, in many cases, less necessary: but for strips, wherever it is practicable, and there is at the same time no danger of the soil being washed away by rains or thaws, as in some chalky hilly districts; or blown about by the wind, as in some parts of Norfolk, and other sandy tracts, preparation by a year's fallow, or by trenching two spits deep, cannot be admitted without real loss, by retarding the attainment of the object desired. There are instances stated of promising oak-plantations from oaks dibbled into soil altogether unimproved; and of plantations of Scotch pine, raised by merely sowing the seeds on a heath or common, and excluding cattle (Gen. Rep. of Scot. ii. 630.); but these are rare cases, and the time required, and the instances of failure, are not mentioned. The practise is obviously too rude to be recommended as one of art. The best situations for planting, without any other culture but inserting the seeds or plants, are surfaces partially covered with low woody growths, as broom, furze, &c. “The ground which is covered, or rather half covered, with juniper and heath,” says Buffon, “is already a wood half made."

6818. Osier-plantations are an exception to these remarks, as to the value of the situation and soil; they require a deep, strong, moist soil, but one not springs; or continually saturated with water; and it will be in vain to plant them without trenching it two or more feet deep.

6819. The form of plantation for profit or shelter must be determined jointly by the situation and the objects in view. In rocky abrupt sites (fig. 632.), the plantation will consist of a number of masses (a, b, c), of forms determined by the rocks and precipices, among which some of the most valuable pasture may be left as glades (d, e), for use, effect, and for the sake of game. Strips and hedges for sheltering or separating arable lands, should be formed as much as possible in straight and parallel lines, in order not to increase the expense of tillage by short and irregular turnings. Straight parallel strips, on irregular surfaces, have a more varied appearance at a distance, than strips ever so much varied on a flat surface; for, in the former case, the outline against the sky is varied as much as that on the earth. In extensive hilly pastures, in which it is often desirable to produce shelter, and at the same time to plant only the most rocky and unproductive spots, the forms may be of the most irregular description; and by planting chiefly on the eminences and slopes (fig. 633.), shelter will be most effectually produced, the pasture improved, the least valuable ground rendered productive in copse or timber, and the greatest richness and picturesque beauty conferred on the landscape. There are some fine examples of this on the hilly districts of Fifeshire; there, on many estates where nothing was sought for but profit and shelter, the greatest beauty has been produced; and the picturesque tourist now passes through glades and valleys, pastured by well-fed cattle and sheep, enlivened by rocks, thickets, hanging woods, and occasional rills and lakes. Fifty years ago, scarcely a tree was to be seen, and only the most inferior descriptions of live stock.

6820. The enclosing of plantations is too essential a part of their formation to require enlarging on. In all those of small extent, as hedges and strips, it is the principal part of the expense; but to plant in these forms, or any other, without enclosing, would be merely a waste of labor and property. The sole object of fencing being to exclude the domestic quadrupeds, it is obvious, that whatever, in the given situation, is calculated to effect this at the least expense, the first cost and future repairs or management being taken into consideration, must be the best. Where stones abound on the
spot, a wall is the best and cheapest of all fences as such; but, in the great majority of cases, recourse is obliged to be had to a verdant fence of some sort, and generally to one of hawthorn. This being itself a plantation, requires to be defended by some temporary barrier, till it arrives at maturity; and here the remark just made will again apply, that whatever temporary barrier is found cheapest in the given situation will be the best. Hedge fences are in general accompanied by an open drain, which, besides, acting in its proper capacity, furnishes, at its formation, a quantity of soil to increase the pasturage of the hedge plants; and an excavation (fig. 634. a), and an elevation (f'), to aid in the formation of a temporary fence. A hedge enclosing a plantation, requires

only to be guarded on the exterior side, and of the various ways in which this is done, the following may be reckoned among the best and most generally applicable. By an open drain and paling, or line of posts and rails (a), the plants inserted in a facing of stone, or in a facing of sub-soil from the bottom of the drain, backed by the earth of the drain (b); an excellent mode, as the plants generally thrive, and almost never require cleaning from weeds; an open drain and paling, and the hedge on the top of the elevation (c); no open drains, but the soil being a loam, the surface-curves formed into a narrow ridge, to serve as a paling, a temporary hedge of furze sown on its summit, and the permanent hedge of thorn or holly within (d); and an open drain, but on the inside, the exterior being protected by a steep bank sown with furze (e). The first of these modes is the most general, the second the best, and the fourth the cheapest, where timber is not abundant. Separation fences are commonly formed in the first, second, or third manner, but with a paling on both sides.

682. Shelter. Many situations are so exposed that it is extremely difficult to rear trees without some mode of procuring shelter for them during their early growth. This is obtained either by walls, the extent of whose influence is very limited; by thick planting, or by planting the more hardy and rapidly growing species, to nurse up and protect such as are more tender, but ultimately more valuable. The proportion of nurses to principals is increased according to the bleakness of the site. Poncy says, "the authors and planters, ..." The practice of this mode is also recommended to exclude the surface-drains, as they generally use as many, or more of the former than the latter; though it is very easy to show, that they ought to use three times as many of the latter as the former. For instance, when trees are planted at four feet apart, each occupies a surface of sixteen feet; of course four of them will occupy four squares of eight feet and therefore, if we plant three nurses to one principal, all the former might be displaced gradually, and the latter would still stand only eight feet apart. Nurse-plants should, in every possible case, be such as are most valuable at an early period of growth. The larch and spruce fir should be used liberally, in every case where they will grow freely; still it is not intended that they should exclude all others, more particularly the larch, which has most of the properties of a good nurse, such as numerous branches and quick growth, on any tolerable soil or situation. It is not, however, like the others, a wood of general application."

683. The commoner methods for the mode of commencing and continuing plantations on bleak sites. Sang, who has had extensive experience on this subject, observes, "that every plain, and most fields and situations for planting, in this country, have what may be called a windward side, which is subject to the destructive blast of the wind in any other. It is of very great importance in the estimation of this circumstance; and to be able to fix upon the most exposed side of the proposed forest plantation. Fix, then, upon the windward side of the plain which is to be converted into a forest; mark off a horizontal stripe, or belt, at least a hundred yards in breadth. Let this portion of ground be planted thick, say at the distance of thirty inches in front three, feet, with a mixture of larch, sycamore, and elder, in equal quantities, or nearly so, if the soil be adapted for rearing these; but if it be better adapted for Scots pines, then let it be planted with them at the distances prescribed for the above mixture. We have no other kinds that will thrive better, or rise more quickly in bleak situations, than those just mentioned. When the trees in this belt, or zone, have risen to the height of two feet, such hard-wood trees as are intended ultimately to fill the ground should be introduced, at the distance of eight or ten feet from each other, as circumstances may admit. This period, or perhaps a year or two afterwards, according to the grounds, let another belt, on the inside of the ground, or on the outside of the belt, be added to the one already so far grown up, and so on, till the whole grounds be covered. It is not easy here to determine on the exact breadth of the subsequent belts or zones: this matter must be regulated by the degree of exposure of the grounds, by the shelter afforded by the zone previously planted, and by such like circumstances." (Plant. Kad. p. 106.)

684. In situations exposed to the sea-breeze a similar plan may be successfully followed, and aided in effect, by beginning with a wall; the first belt having reached the height of the wall, plant a second, a third, and so on till the whole tract be occupied. In this way the coast of the north, the coast of the east coast of Mid-Lothian, round Gossford House, were reared; and in Sang's manner, the mountains of Blair and Dunkeld were clothed; and examples, we are informed, might be drawn even from the Orkney and Shetland islands.

**Note:** The text provided is a transcription of the content visible in the image. It represents the natural text as it would be read. The transcription does not include any diagrams, tables, or other visual elements that might be present in the original document. The content focuses on the formation and protection of plantations, particularly in exposed or challenging environments, and includes recommendations for the use of various species and methods of planting.
soils, and its state in respect to water and climate, than on its constituent principles; moderately sheltered and on a well-drained sub-soil, it signifies whether the surface strata be a clayey, sandy, or calcareous loam. All the principal trees will thrive nearly equally well in either so circumstanced; but no tree whatever, in or in any other soil saturated with water, and in a bleak exposed site. For hedge-row timber, those kinds which grow with lofty stems, which draw their nourishment from the sub-soil, and do not injury by their shadows may or may not. These, according to Blakie, are oaks, narrow-leaved elm, and black Italian poplar; beech, ash, and firs, he says, are ruinous to fences, and otherwise injurious to farmers. (On Hedges and Hedge-row Timber, p. 10.)

6825. The common practice in planting is to mix different species of trees together, which is unavoidable where nurse or shelter plants are introduced; where these are not wanted, the opinions of planters are divided on the subject. Mixing different sorts is most generally approved of. Marshall advises mixing the ash with the oak, because the latter draws its nourishment chiefly from the sub-soil, and the former from the surface. Nicol is an advocate for indiscriminate mixture (Practical Planter, p. 77.); and Pontey says, “both reason and experience will fully warrant the conclusion, that the greatest possible quantity of timber is to be obtained by planting mixtures.” (Prof. Planter, p. 119.)

6826. Sang is “clearly of opinion, that the best method is to plant each sort in distinct masses or groups, provided the situation and quality of the soil be properly kept in view. There has hitherto been too much random work carried on with respect to the mixture of different kinds. A longer practice, and more experience, will discover better methods in any science. That of planting is now widely extended; and improvements in all its branches are introduced. We, therefore, having a better knowledge of soils, perhaps, than our forefathers had, can, with greater certainty, assign to each tree its proper station. We can, perhaps, at sight, decide, that here the oak will grow to perfection, there the ash, and the same with respect to the others. If, however, there happen to be a piece of land of such a quality, that it may be said to be equally adapted for the oak, the walnut, or the Spanish chestnut, it will be proper to place such in it, in a mixed way, as the principals; because each sort will not extract its own proper nourishment from the soil, and will be adapted to the most valuable sorts, and the same with respect to the others. This is hardy one of the principal objects of our plantations. We have known this imperfection in several instances severely felt. It not unfrequently happens, too, that even what oaks, or other hard-wood trees, are to be met with, are overtopped by less valuable kinds, or perhaps, such all things considered, can be prevented by planting with attention to the soil, and in distinct masses. In these masses are ensured a full crop, by being properly nursed, for a time, with kinds more hardy, or which afford more shelter than such hard-wood plants. There is no rule by which to fix the size or extent of any of these masses. Indeed, the more variously they be placed, the better, in size, and in the eye, the person of taste. They may be extended from one acre to fifty or a hundred acres, according to the circumstances of soil and situation: their shapes will accordingly be as various as their dimensions. In the same manner ought all the residuum kinds to be planted, which are intended for timber-trees; much should these be intermixed with any other sort, but be in distinct masses by themselves. The massing of larch, the pine, and the fir of all sorts, is the least laborious and surest means of producing good, straight and clean timber, by placing them thick, by a uniform pruning and gradual thinning, that we can, with certainty, attain to this object.” (Plant. Kal. 162.)

6827. Our opinion is in perfect consonance with that of Sang, and for the same reasons; and we may add as an additional one, that in the most vigorous natural forests one species of tree will generally be found occupying almost exclusively one soil and situation, while in farm forests, where the ash and here, there, and in all the various species of taste. They may be extended from one acre to fifty or a hundred acres, according to the circumstances of soil and situation: their shapes will accordingly be as various as their dimensions. In the same manner ought all the residuum kinds to be planted, which are intended for timber-trees; much should these be intermixed with any other sort, but be in distinct masses by themselves. The massing of larch, the pine, and the fir of all sorts, is the least laborious and surest means of producing good, straight and clean timber, by placing them thick, by a uniform pruning and gradual thinning, that we can, with certainty, attain to this object.” (Plant. Kal. 162.)

6828. Whether extensive plantations should be sown or planted, is a question about which planters are at variance. Miller says, transplanted oaks will never arrive at the size of those raised where they are to remain from the acorn. (Dict. Quercus.) Marshall prefers sowing when the ground can be cultivated with the plough. (Plant. and Rur. Oen. i. 123.) Evelyn, Emmerich, and Speedely are of the same opinion; Pontey and Nicol practise planting, but offer no arguments against sowing where circumstances are suitable. Sang says, “It is an opinion very generally entertained, that planted timber can never, in any case, be equal in durability and value to that which is sown. We certainly feel ourselves inclined to support this opinion, although we readily admit, that the matter has not been so fully established, from experiment, as to amount to positive proof. But although we have not met with decided evidence, to enable us to determine on the comparative excellence of timber raised from seeds, without being replanted, over such as have been raised from replanted trees, we are left in no doubt as to the preference, in respect of growth, of those trees which are sown, over such as are planted.” (Plant. Kal. 43.) He particularly prefers this mode for raising extensive tracts of the Scotch pine and larch (p. 430.), and is decidedly of opinion, “that every kind of forest tree will succeed better by being reared from seeds in the place where it is to grow to maturity, than by being raised in any nursery whatever, and from thence transplanted into the forest,” (p. 344.) Dr. Yule (Caled. Hort. Mem. ii.), in a long paper on trees, strongly recommends sowing where the trees are finally to remain. “It is,” says he, “a well ascertained fact, that seedlings allowed to remain in their original station will, in a few seasons, far overtop the common nursed plants several years older.”

6829. The opinion of Dr. Yule, and in part also that of Sang, seems to be founded on the idea that the tap-root is of great importance to grown-up trees, and that when this is once cut off by transplanting, the plant has not a power of renewing it. That the tap-root is of the utmost consequence for the first three or four years is obvious from the economy of nature at that age of the plant; perhaps for a longer period:
FORMATION OF PLANTATIONS.

but that it can be of no great consequence to full-grown trees, appears highly probable from the fact, that when such trees are cut down, the tap-root is seldom to be distinguished from the others. The opinion that young plants have not the power of renewing their tap-root, will, we believe, be found inconsistent with fact; and we may appeal to Sang and other nurserymen, who raise the oak and horse-chestnut from seed. In cutting the tap-roots, these are often cut off to tap-roots too thick; tapping the young plants at the end of the second year's growth, and when at the end of the third or fourth year they are taken up, they will be found to have acquired others, not indeed so strong as the first would have been had they remained, but sufficient to establish the fact of the power of renewal. We may also refer to the experiment recorded that trees have a power of renewing their tap-roots after the most extraordinary accidents. The great advantages from cutting down trees after two or three years' planting. Forthry planted a bed of oak-plants, cutting the tap-roots near to some of the side-roots or fibres springing from them. In the following year, these plants have been cut down at the same time as the other half, and the plants left in the season, those headed down made shoots six feet long and upwards, and completely covered the head of the old stem, leaving only a faint cicatrix, and produced new tap-roots upwards of two feet and a half long. The other half of the plants that were not headed, were not one fourth the size of the others. One of the formations which have six feet high, and fifteen inches in circumference, at six inches from the ground; one of the largest of the latter measures only five feet and half in height, and three inches and three quarters in circumference, at six inches from the ground. (Tr. on Fruit Trees, 4to ed. 14.) The pine and fir trees, if only released from the age of four or five years, when they are of any size, will arrive at trees afterwards; those we should, on most occasions, prefer to sow, especially on mountainous tracts.

For all trees which stole, and in tolerable soils and situations, planting strong plants, and cutting them down two or three years afterwards, will, we think, all circumstances considered, be proved preferable to sowing.

6830. On the subject of disposing the plants in plantations, there are different opinions; some advising rows, others quincunx, but the greater number plant irregularly. According to Marshall, the preference to be given to the row, or the random culture, rests in some measure upon the nature and situation of the land to be stocked with plants. Against steep slopes, where the plough cannot be conveniently used in cultivating and cultivating the interspaces, during the infancy of the wood, either method may be adopted; and if plants are to be put in, the quincunx manner will be found preferable to any. But in most situations the manner advantageously presents the liberty of choice; the drill or row manner is undoubtedly the most eligible. (Plant. and Rur. Orr. p. 153.) Poncet considers it of much less consequence than most people imagine, whether trees are plant regularly or irregularly, as in either case the whole of the soil will be occupied by the shoots and the surplus by the horse-hoe. In the latter plan, in rows where culture with the horse-hoe is to be adopted. In sowing for woods and copses, the former places the patches six feet asunder and in the quincunx order. It has been demonstrated (Farmer's Mag. viii. 463), that the closest order in which it is possible to place a number of points, upon a plain surface, not nearer than the angles of hexagons, with a plant in the centre, forms a triangle. Hence it is argued, that this order of trees is the most economical; as the same quantity of ground will contain a greater quantity of trees, by 15 percent. when planted in this form than in any other. (Gard. Mag. 1867.) We observe, that hedge plants should be placed at regular distances in the lines, and also the trees, when those are introduced in hedges. Osier plantations, and all such as like them require the soil to be dug every year, or every two years, during their existence, should also be planted in regular rows.

6831. The distances at which the plants are placed must depend on different circumstances, but chiefly on the situation and soil. Planting thick, according to Nicol, is the safer side to err on, because a number of plants will fall, and the superfluous ones can be easily removed by thinning. For bleak situations, he observes, that from thirty to forty inches is a good medium, varying the distance according to circumstances. For less exposed situations, and where the soil is above six inches in depth, he recommends a distance from four to five feet. For belts, clumps, and strips, of a diameter of about one hundred feet; the margin to be planted about the distance of two feet, and the interior at three feet. In sheltered situations of a deep good soil, he recommends a distance of six feet, and no more. (Proct. Plant.)

6832. According to Sang, the distances at which hard-tember trees ought to be planted are from six to ten feet, according to the quality of the soil, and the exposed or sheltered situation. When the first are cut, they are left at their full size, as the sight of tree that was to fall are filled up with five nurses, the whole standing at four and a half feet asunder. When sixteen oaks are planted, there will necessarily be thirty-three nurses planted; and when thirty-six oaks are planted, eight in a line, and twenty seven trees are planted, each thirteenth tree is a nurse, or nearly a tree, and the nurses will be on the one side, there will be two hundred and sixty-one nurse-plants required. The English acre would require five hundred and thirty-six oaks, and one thousand six hundred and ten nurses. (Plant. Ktol. 183.) Poncet says, in general cases, a distance of four feet is certainly close enough; as at that space the trees may all remain till they become salubrious as rails, spars, &c.

6833. The number of plants which may be planted on a statute acre = 160 rods, or poles, = 4840 yards = 43,560 feet, is as follows:—

6834. The size of the plants depends jointly on the site and the kind of tree; it is universally allowed that none of the resinous tribe succeed well when removed at four or more years' growth; but if the soil is of tolerable quality, prepared by digging or summer pitting, and the site not bleak, plants of such hard woods as stule may be use whose stems are an inch or more in diameter.

6835. Nicol is of opinion, that generally trees three, or at most four, years old from the seed, and which are from twelve to twenty-four inches high, will, in any situation or soil, outgrow those of any size under eight or ten feet, within the seventh year. (Proct. Plant. 130.)

6836. The size of the different plantations must, in some measure, depend on their kinds; but it may be said, generally, that the plants being transplanted, they should be from a foot to eighteen inches in height, stiff in the stem, and well rooted. Plants for this purpose should seldom be more than three years from the seed; indeed never, if they have been raised in good soil. Many of
PRACTICE

In the end, it will be seen, that for the purpose of which the seed-bed is used, and has been transplanted for one season. This is supposing it to have risen a weakly plant; for, if the lamb rise strong from the seed the first season, it should never stand a second in the seed-bed. The ash, the elm, and the sycamore, one young plant may be transplanted in good soil for a second season; but plants. If they be weakly, they may stand two years in the seed-bed; and then being nursed one season in good soil, will be very fit for planting out in the forest.

The oak, the beech, and the chestnut, if raised in rich soil, and well furnished with roots at the end of the first year, and if the seed be sown in rich soil, will be very fit to stand two years in the seed-bed, and be planted one year in good ground, they will be still better, and the roots will be found well feathered with fine small fibres. The silver fir and common spruce should stand two years in the seed-bed. If transplanted into very good soil, they may be fit for being planted out at the end of the first year; but, more generally, they require two years in the seed-bed. The Scots pine should also stand for two years in the seed-bed, and should be nursed in good ground for one year; at the end of which they will be much fitter for being planted, than if they were allowed to stand a second year in the lines. They are very great stock, and can be raised from coarse seed-bed, and in land bare of heath or herbage, they succeed pretty well; nevertheless, we would prefer them one year nursed. The above are the hardest and most useful forest trees; and from the observations made, whatever respects the age or size of other kinds, may easily be inferred." (Plant. Kal. 158.)

6857. According to Pott, the best general rule is, to propagate the goodness of soil; the best of the latter requiring the largest of the former. Still on bleak exposures this rule will not hold good, as there the plants should never be allowed, for otherwise the greater part would fall from the circumstance of wind-waving, and of those that succeeded, few, if any, would make much progress for several years; firs of a foot, and deciduous trees of eighteen inches, both transplanted. None but plants, which will succeed, or succeed well, should be thus transplanted. A great number of wood-solts, which do succeed, will fail; a large plant never has so good a root, in proportion to its size, as a small one; and hence we see the propriety of using such on good soils only. Small plants lose but few of their roots in removal; therefore, though planted in very moderate-sized holes of pulverised earth, they often prove sufficiently strong plants. It should never be forgotten that, in being removed, a plant of two feet loses a greater proportion of its roots than a tree of one, and one of these a greater proportion than one of two, and so on, in proportion to its former strength and height, and thus the larger the plants, so much greater the degree of languor or weakness in which they are thrown by the operation of transplanting." (Prof. Plant. 161.)

6838. The seasons for planting are autumn and spring; the former, when the soil and situation are moderately good, and the plants large; and the latter, for bleak situations. Necessity, however, is more frequently the guide here than choice, and in extensive designs, the operation is generally performed in all moderately dry open weather from October to April inclusive. "In an extensive plantation," Sang observes, "it will hardly happen but there will be variety of soil, some parts moist and heavy, and others dry and light. The lightest parts may be planted in December or January; and the more moist, or damp parts, in February or March. It must be observed, however, that if the ground be not in a proper case for planting, the operation had better be delayed. The plants will be injured, either by being committed to the ground when it is in a sour and wet, or in a dry parched state. At a time when the soil may be termed neither wet nor dry, the operation of planting is most successfully performed. The mould does not then adhere to the spade, nor does it run in; it divides well, and is made to intermingle with the fibres of the plants with little trouble; and in treading and setting the plant upright, the soil is not worked into mortar, which it necessarily must be, if in a wet state, evidently to the great detriment of the plants. It is therefore improper to plant on a retentive soil in the time of rain, or even perhaps for some days afterwards, or after a fall of snow, until it has for some days disappeared. Whereas, on a dry absorbent soil, it may be proper to plant in the time of gentle showers, immediately after heavy rains, or as soon as the snow is dissolved." (Plant. Kal. 157.)

6839. Poemry is a decided advocate for autumn preparation of the soil, and spring planting. "Autumn planting," he says, "is advisable only in few cases, while spring planting may properly apply to all."  

6840. According to Sang, the proper time for planting the pine and fir tribes, and all evergreens, is April or even the first fortnight in May. "Attention should be paid, that no greater number of plants be lifted from the nursery than can be conveniently planted on the same day. Damp weather is the best. When very dry, and the plants rise destitute of earth at the root, the roots will be so much injured, if to be continued, that the plants should be set in the ground not later than the middle of April. He also states that the care should be taken, if adorning earth from plants at the time of planting," (Plant. Kal. 341.)

6841. The operation of inserting the plants in the soil is performed in various ways; the most general mode, and that recommended by Marshall and Nicol, is pitting; in which two persons are employed, one to operate on the soil with the spade, and the other to insert the plant and hold it till the earth is put round it, and then press down the soil with the foot. Where the plants are three feet high or upwards, this is the best mode; but for smaller plants modes have been adopted in which one person performs the whole operation.

6842. Sang describes three kinds of manual operation employed by him in planting, and in part in some trees: by pitting; by slitting simply, or by cross, or T slitting; by the diamond dibber; by the planting-mattock; and by the planter. In filling an area with plants, he first plants those intended as the final trees, and afterwards the nurses; or one set of operators plant the former, while another follow with the latter, unless 0 time for the best general mode, as in the case of the pines and firs, should be the former than that for planting the principals. (6832.) "The plants, if brought from a distance, should be
6843. *By pitting.* "The pit having been dug for several months, the surface will therefore be encrusted by the rains, or probably covered with weeds. The man first strikes the spade downwards to the bottom, two or three times, in order to loosen the soil; then poaches it, as if mixing mortar for the builder; he next lifts out a spadeful of the earth, or, if necessary, two spadefuls, so as to make room for all the fibres, without their being anywise crowded together; he then chops the rotten turf remaining in the bottom, and levels the whole. The boy now places the plant perfectly upright, an inch deeper than when it stood in the nursery, and holds it firm in that position. The man *trudges* in the mould gently; the boy gently moves the plant, not from side to side, but upwards and downwards, until the fibres be covered. The man then fills in all the remaining mould; and immediately proceeds to chop and poach the next pit, leaving the boy to set the plant upright, and to tread the mould about it. This in still wet soil he does lightly; but in sandy or gravelly soil he continues to tread until the soil no longer retains the impression of his foot. The man has by this time got the pit ready for the next plant, the boy is also ready with it in his hand, and in this manner the operation goes on. On very steep *hongs* which have been pitted, the following rule ought to be observed in planting: to place the plant in the angle formed by the acclivity and surface of the pit; and in finishing to raise the outer margin of the pit highest, whereby the plant will be made to stand as if on level ground, and the moisture be retained in the hollow of the angle, evidently to its advantage." (*Plant. Kri. 167.*)

6844. *The silt method,* either simply (3988.) or by the T method, is not recommended by Sang; but necessity may justify its adoption occasionally. "We would not recommend planting by the silt, unless where there is no more soil than is absolutely occupied by the fibres of the herbage which grows on the place. Excepting on turf, it cannot be performed; nor should it be practised, if the turf be found three or four inches thick. By pitting in summer, turf is capable of being converted into a proper mould in the space of a few months; and the expense of pitting, especially in small plantations, can never balance the risk of success in the eyes of an ardent planter. The most proper time to perform the operations is the second, and the silt is less objectionable. On all stony places, the soil should be placed towards the declivity, that the moisture may fall to its roots; that is to say, in planting, the spademan should stand highest, and the boy lowest on the bank; by which arrangement the plant will be inserted at the lower angle of the silt." (*Plant. Kri. 170.*)

6845. *Planting with the diamond dibber,* he says, "is the cheapest and most expeditious planting of any we yet know, in cases where the soil is a sand or gravel, and the surface bare of herbage. The plate of the dibber (fig. 633. a) is made of good steel, and is four inches and a half broad where the iron handle is welded to it; each of the other two sides of the triangle is five inches long; the thickness of the plate is one fifth part of an inch, made thinner from the middle to the sides, till the edges become sharp. The length of the iron handle is seven inches, and so strong as not to bend in working, which will require six fortnights of an inch square. The iron handle is furnished with a turned hill, like the handle of a small gimlet, and a notch or square at its forehead, where the dibber is fixed on. The planter is furnished with a planting-bag, tied round his waist, in which he carries the plants. A stroke is given with the dibber, a little slant, the point lying inwards; the handle of the dibber is then drawn towards the person, while its plate remains within the ground, so that its cavity is turned between the person and the planter, with his other hand, introduces the roots of the seedling plants, being careful to put them fully to the bottom of the opening; he then pulls out the dibber, so as not to displace them, and gives the eased turf a smart stroke with the heel; and thus is the plant completely fixed. The greatest error the planter with this instrument can run into, is the imperfect introduction of the roots. Green, or unpractised hands, are apt to double the roots, or sometimes to lay them across the opening, instead of putting them straight down, as above directed. A careful man, however, will become, if not a speedy, at least a good planter in one day, and it is of great importance that he be a sure hand, than a quick one. A person who is of a careless or slovenly disposition, should never be allowed to handle a dibber of this kind."

6846. *Planting with the planting-mattock* (fig. 633. b) is resorted to in rocky or other soils where pitting is impracticable. "The half or handle is three feet six inches long; the mouth is five inches broad, and is made sharp; the length from it to the eye, or helve, is sixteen inches; and it is used to pare off the sward, heath, or other brush that may happen to be in the way, previous to casing the soil with the other end. The small end tapers from the eye, and terminates in a point, and is seventeen inches long." By this instrument the surface is skimmed off "for six or eight inches in diameter, and with the pick-end dug down six or eight inches deep, bringing up any loose stones to the surface; by which means a place will be prepared for the reception of the plant, little inferior to a pit. This instrument may be used in many cases, when the plants to be planted are of small size, such as one-year larch-seedlings, one year nursed; or two-year Scots pines, one year nursed; and the expense is much less than by the spade." (*Plant. Kri. 385.*)

6847. *Planting with the forest-planner.* (fig. 633. c) "The helve is sixteen inches long, the mouth is four inches and a half broad, and the length of the head is fourteen inches. The instrument is used in planting hilly ground, previously prepared by the hand-mattock. The person who performs the work carries the plants in a close apron; digs out the earth sufficiently to hold the roots of the plant; and sets and firms it
without help from another: it is only useful when small plants are used, and in hilly or rocky situations."

(Plant. Kal. Pref. xxiv.)

Ponsey prefers planting by sowing, in general cases; the soil being made during the preceding summer or winter, sufficiently large, but not so deep into a retentive sub-soil as to render them a receptacle for water. When the plants have been brought from a distance, they are placed in a strongframe quite dry. It would be still better to lay them in the ground for eight or ten days, giving them a good soaking of water every second or third day, in order to restore their vegetable powers; for it well deserves notice, that a degree of moisture in soil sufficient to support a plant recently or immediately taken from the nursery, without the care of them in any way injured, proves so far that much of them will live in it. The puddling here recommended may also be of great service in all cases of late planting when small plants are used; my method is (after puddling) to tie them in bundles, of two or three hundreds each; and then send them, by a cart-load at once, to where wanted; where such bundles being set upon their feet, close to each other, and a little straw carefully applied to the outside of them, may remain without damage in a sheltered situation any reasonable time necessary to plant them. Where loose soil happens to be convenient, that should be substituted in the place of straw.

A puddle for trees is made by mixing water with any soil rather tenacious, so intimately as to form a complete puddle, so thick that when the plants are dipped into it enough may remain upon the roots to cover them. The process of puddling is certainly simple, and its expense too trifling to deserve notice: its effects, however, in retaining, if not attracting, moisture, are such that, by means of it, late planting is rendered abundantly more safe than it otherwise would be. It is an old invention, and hence it is truly astonishing that it is not more frequently practised. If we could but persuade people to adopt it generally in spring planting, I believe the prejudice in favor of autumn practice would soon be done away. (Prof. Plant. 161.)

Ponsey's methods of planting are in general the same as those of Sang: he uses a mattock and planter of similar shape; and also a two or three pronged instrument, which we have elsewhere denominated the planter's hack. (1.65. fig. 90.) "This instrument," he says, "I have himself recommended, and is an improvement on the mattock and planter (fig. 655. b, c), being better adapted to soils full of roots, stones, &c., as they are likewise easier to work, as they penetrate to an equal depth with a stroke less violent than the former: they are also less subject to be clogged up by a wet or tenacious soil. The length of the prongs of both should be about eight inches, and the distance between them when in use about one-half a yard; the two-pronged about two inches; the two-pronged hack should be made somewhat stronger than the other, it being chiefly intended for very stony lands, or where the soil wants breaking, in order to separate it from the heritage, &c. These tools are chiefly applied to planting of any size up to about two feet, or such parts of any great design as are used as a substitute for the spade, in the following manner: The planter being provided with a basket holding the plants required (the holes being supposed prepared, and the earth left in them), he takes a tree in one hand, and the tool in the other, which he strikes into the hole, and then pulls the earth towards him, so as to make a hole large enough to astonished: It is an old invention, and hence it is truly astonishing that it is not more frequently practised. If we could but persuade people to adopt it generally in spring planting, I believe the prejudice in favor of autumn practice would soon be done away. (Prof. Plant. 161.)

On forming Plantations, in which Ornament or Effect is the leading Consideration.

Designing ornamental plantations, the situation, form, the disposition of the trees, and the kinds employed, are the principal considerations.

The situations to be planted, with a view to effect, necessarily depends on the kind of effect intended; these may reduced to three — to give beauty and variety to general scenery, as in forming plantations here and there throughout a demesne; to give form and character to a country-residence, as in planting a park and pleasure-grouunds; and to create a particular and independent beauty or effect, as in planting an extensive area or wood, unconnected with any other object, and disposing of the interior in avenues, glades, and other forms. In the two first cases, the choice of the situation must always be relative to other objects; as, for example, in ornamenting general scenery, to fields and enclosures, buildings, roads, &c.; and to the mansion-garden and other parts of a residence, in laying out a country-seat: but in forming independent plantations the choice may be absolute, and guided by no other consideration than the effect to be produced. One of the greatest beauties produced by planting, either on general scenery, or on the grounds of a residence, is that of varying the form of the surface of the landscape.

Without help from another: it is only useful when small plants are used, and in hilly or rocky situations.
or increasing the variations already existing. To do this with most effect, it is an obvious and long established principle, that, other circumstances being the same, the hills are to be more generally planted than the hollows, or even the plains. By planting a hill, or the least rise of ground, that hill or rise is increased in effect; but by planting the low grounds between hills or protuberances, their effect is destroyed. It is to be observed, however, that the latter practice is often what we observe in natural scenery. In hilly tracts in a state of nature, and under the dominion of no other animals than cattle or sheep, the vales or dells (fig. 637.) are generally filled with wood and the tops of the hills bare, which, however agreeable to those who view or study nature chiefly in detail, yet to the general observer it tends to confound form, and introduce monotony of surface. Art, therefore, when planting for general effect, or for heightening the character of surface, adopts a contrary practice (fig. 638.) to what is general in wild nature; for few things in a wild state are suitable to the views of man in a state of civilisation and refinement; and when he admires rude scenery, it is from views of its novelty or rarity in cultivated countries; or with reference to some other art or object, or state of the same object. At the same time, a hill crowned with wood occurs in nature occasionally, both with and without naked hollows or plains at its base, and never fails to excite a superior degree of satisfaction or pleasure in the spectator. To plant hills, therefore, in preference to valleys, may justly be designated an imitation of one of the more interesting features of nature.

634. With respect to form, it may be absolute, or independent of every consideration but the taste of the designer; or it may be relative. It is absolute in plantations intended to create particular beauties within themselves; as in labyrinths, woods pierced with avenues, stars, &c., in the geometric style; or in compositions and groups, thickets and glades in the interior of a wood, laid out in the modern manner. It is relative to the shapes of the ground and to existing objects in the forms adapted for improving general scenery; and to these considerations, and to the situation and form of the mansion, gardens, waters, &c. in laying out the grounds of a country-residence. For either of these objects the general principles of operation are to heighten beauties already existing; to conceal defects; if possible, to create beauty; and to connect detached objects, either in reality or appearance, so as the scenery, from whatever point it may be viewed, may appear a whole; in short, the end is a harmonious and expressive whole, and the means are the grouping and connecting of the parts. Some tracts of country, or those parts of a demesne exterior to the park, may be deficient in woodiness; there trees may be introduced in masses on elevated sites, or the sides of hills; in groups connected with buildings; in thinly scattered trees, in pastures, and by brooks; and in rows in hedges, and by other fences or roads. Where disagreeable objects are to be concealed, the course is evident; and where nothing is interesting, attempts must be made to create interest. A road through a dreary country may often have much of its dulness taken away by one or two rows of trees on each side, the stems of which will break and vary the distant scenery. The lines may vary in form and direction, may swell into strips, or clumps, or thickets; form recesses, or be interrupted, according to circumstances. The route through some of the most dreary tracts in Germany and Russia, and the well-known Strada di Campagna, in Italy, are in this way rendered tolerable. In all this, though the main object may be beauty, yet, utility must never be lost sight of. All plantations by arable lands should, as much as possible, be bounded by straight, or at least not very irregular lines, and connected with the hedges or other fences already existing; few single trees or groups should be planted in the area of such fields. In pastures, the worst soils and most exposed situations should be chosen, and such forms adapted as may shelter the stock from all quarters, but especially from the storms and winds which more generally prevail. In planting near cottages and villages, care should be taken not to render the atmosphere unhealthy by stagnating the air, or to lessen the value of their yards and gardens by curtailing their extent, or by excess of shelter and shade. Roads or lanes should on no account be injured, nor the water of streams and ponds rendered dark, discolored by leaves, and unwholesome to men or cattle. In short, the planter, for effect, should never lose sight of utility, or plant in opposition to it; for though he may produce particular sorts of beauty, and especially that lately so fashionable and justly admired disposition of objects, called picturesque, which may be admired by a number for a time; yet there is a much more elevated and universal beauty, that of moral relation, or, in short, refined utility, which, while men
retain their social feelings, must ever be the most interesting to mankind in general, and will therefore finally prevail.

6855. The outline of plantations, made with a view to the composition of a country-residence, is guided by the same general principles; whether the trees are to be disposed in regular forms, avowedly artificial; or in irregular forms, in imitation of nature. (fig. 639.) The first thing is, in both modes, to compose a principal mass, from which the rest may appear to proceed; or be, or seem to be, connected. In common cases it answers best to include or connect with this mass the house, kitchen and flower-gardens (e); from these other masses and groups should proceed, either connected, or better, only seemingly so when viewed horizontally. Their forms should be such

and so disposed, relatively to the ground and other objects, and to each other, as to throw the pasture surface into broad masses (a, b, c, d), which become wholes in their turn, and their connection and variation is heightened by the variety in the glades between the masses and groups of plantation. Such would be the mode of procedure on a flat to be formed into a modern park; regard being had to exclude or admit the view of certain parts of the distant scenery; never to shut in, or leave without a third distance (as is the term in landscape-painting), any of the scenes within the boundary of the park; and to other laws of perspective, optics, and composition, which will be more fully entered on in treating of landscape-gardening.

6856. In the pleasure-ground, which, as far as respects the form or ground outline of plantations, is to be considered as a part of the park, the same principles are applicable. In neither the artificial or natural style, should their width be great; but their form may be varied at pleasure, subject to general principles. Where the ground is irregular (fig. 640.), only the modern style can be adopted with good effect; and there, by con-

ducting the walks, or forming the water chiefly in the hollows (a), and planting the eminences (b), varying the manner in which the outlines of these masses embrace the declivities, the happiest effects may be produced. Deviations from these general principles can only be justified by extraordinary circumstances.
FORMATION OF PLANTATIONS.

6857. With respect to the extent, or area, occupied by ornamental plantations, as such, that need seldom be great. They are generally seen only in profile, and therefore a circuitous outline (fig. 641. a.) may on most occasions be contrived to have the same effect as planting a solid mass, which will occupy much more ground (b), show less exterior variety, and none within. The case is different, however, where the upper surface of a plantation is to be met by the eye, at a large angle, say upwards of 35°. In that case, to produce a grand and imposing effect, real extent is wanting. Examples occur in planting the steep sides of high hills, to be seen from below; or valleys or plains to be seen from great elevations. It must be confessed that these are among the grandest circumstances in which wood can be viewed; profiles of outlines, varied both as respects the sky and the ground, are beautiful and interesting; and avenues and long rows of trees form imposing perspectives; but the side of a range of mountains clothed with wood, seen at a certain distance, from a plain below or opposite hills, is one of the most magnificent of rural prospects.

6858. With respect to the disposition of trees in a plantation where art is avowed or purposely displayed, the more regularly the plants are placed the better is the effect attained; but, where nature is to be imitated, irregularity will best sustain the character. This should be studied in the larger as well as the smaller plantations, in the natural style; but more especially in detached groups, which operate so powerful an effect in laying out the grounds of a residence. The greatest beauty of a group of trees as far as respects their stems, is in the varied direction these take as they grow into trees (fig. 642.); but as that is for all practical purposes beyond the influence of art, all we can do is to vary as much as possible the ground-plans of groups, or the relative position which the stems have to each other, where they spring from the earth. This is considerable, even where a very few trees are used, and of which any person may convince himself by placing a few dots on paper. Thus, two trees (fig. 643.), or a tree and shrub, which is the smallest group, may be placed in three different positions with reference to a spectator in a fixed point: if he moves round them they will first vary in form separately, and next (at b) unite in one or in two groups, according to the position of the spectator. In like manner three trees (fig. 644.) may be placed in four different positions; four trees may be placed in eight different positions (fig. 645.); five trees may be grouped in ten different ways as to ground-plan (fig. 646.); six may be placed in twelve different positions (fig. 647.); and so on.

6859. In planting groups it is not meant to be asserted, that the ground-plan of each should be studiously considered; it will be sufficient if this is done in conspicuous situations, by the sides of walks and roads, and in such places as require for shelter or shade, or to exclude some disagreeable object, a series of groups of nearly the same number of trees. For the ordinary purposes of grouping, such as varying the apparent outline of masses, connecting scattered objects, adding parts to such objects as are incomplete wholes, &c., it will be sufficient to introduce large and small groups; never to put two trees at exactly the same distance from each other; three in the angles of an equilateral triangle; four in those of a square; five in those of an octagon; and so on.
6860. Scattered trees. It has been a very common practice among planters to introduce, in parks, great numbers of detached single trees (in vulgar technology, dotting), with a view of effecting, by them, what can only be done by groups. Excepting the clump, there is not a greater deformity in the grounds of British country-residences. Supposing these trees, planted on a level surface, all of the same sort, and all growing equally well, their insipid sameness of form and position must be evident to the mind's eye of every one. Suppose them on the same character of surface, but all, or chiefly, of different sorts (fig. 648.), it is equally evident they will grow with different degrees of vigor, and assume different characters of stem and head; and consequently produce an appearance of the most discordant kind. It is only necessary to analyse a group, to be convinced of the variety of general form produced, even by trees of one species, but more especially by two kinds, and this, even by specimens that would be unsightly apart; and to observe a portion of the scattered woody scenery, in the openings or glades of a natural forest, to be convinced how much more variety is produced by that manner of planting, than by distributing over a surface great numbers of single trees. It is observed by Uvedale Price, that in the numerous landscapes which compose the liber veritatis of Claude, there is not more than one single tree; so highly did this artist value the principle of connection. A single tree, however, is not always to be condemned, even as such, for its form, age, or blossom, or some other accidental circumstance may compensate for its isolated situation; and it may often exist singly as a tree, and yet in connection or grouped with other objects, as buildings, rocks, &c.; and in these cases it is not to be condemned, because the grand object of grouping, connection, is maintained by the co-tangent object.

6861. Placing the groups. Another practice in the employment of groups, almost equally reprehensible with that of indiscriminate distribution, is that of placing the groups and thickets in the recesses, instead of chiefly employing them opposite the salient points. The effect of this mode is the very reverse of what is intended; for, instead of varying the outline, it tends to render it more uniform by diminishing the depth of recesses, and approximating the whole more nearly to an even line. The way to vary an even or straight line or lines, is here and there to place constellations of groups against it (fig. 649. c); and a line already varied is to be rendered more so, by placing large groups against the prominences (a) to render them more prominent; and small groups (b), here and there in the recesses, to vary their forms and conceal their real depths.

6862. In all plantations in the natural style above the size of a group, the same general principles are to be followed in the disposition of the trees; the plants, whatever be their kinds, and whether the mass is finally to assume the character of a wood, grove, or cese, should be placed irregularly, here thick, and there thin, as if they had sprung up from the accidental semination of birds or winds. "The effect of this arrangement will not be that composition of low and high, oblique and upright stems, and young and old trees, and low growths, which we find in forest scenery; but it is all that can be done in imitation of it at the first planting; and subsequent thinning, pruning, and cutting down, moving, renovating, planting, and sowing, must be used from time to time to complete imitation or allusion, unless the owner will rest satisfied with an inferior degree of beauty."

6863. The general form of tree employed materially influences the effect of plantations. The capacities of different trees for producing effects in landscape, and the general division of trees into round-headed, oblong-headed, and spiry-toft, have been already pointed out (6795. et seq.) It has also been observed (6857.), that the greater number of plantations are seen chiefly in profile; and hence, that the outline which the tops of the trees form against the sky or the back-ground, is the most conspicuous feature in their aspect. The difference between this outline, when formed of spiry-toft trees, as the firs, pines, &c. (fig. 650.); of oblong-headed trees, as most of the willows, alders, poplars (fig. 651. b); and the round-headed sorts, as the oak, ash, elm, and most trees (fig. 651. a),
FORMATION OF PLANTATIONS.

650

is so considerable, as to merit the particular attention of the planter. Nothing can be more harsh and unvaried than the serrated outline of the fir tribe, whether planted in rows, strips, or masses; whereas the rounded-headed trees, even in single rows, produce some variety of sky outline. The difference is equally great between the face or front surface of a row or mass of spiry and round-headed trees; for the great regularity and similarity of the branches of the former, precludes the possibility of breaks in form, or light and shade, and presents one uniform surface of verdure, not unlike the side of a high hedge. The front surface of a row or mass of round-headed trees, on the contrary, from opposite qualities in the branches, produces prominences and recesses of different degrees of magnitude, and of different forms and relative positions. If we look on the upper surface of a plantation of each class, we shall find the difference equally great.

651. The situations where spiry-topt trees have most effect is among rocks, and in very irregular surfaces; and especially on the steep sides of high mountains (fig. 652), where their forms, and the direction of their growth, seem to harmonise with their pointed rocky summits. Fir and pine forests are dull, gloomy, and monotonous in the sandy plains of Poland and Russia, but among the broken rocks, craggy precipices, and otherwise endlessly varied surfaces of Sweden and Norway, they are full of variety. In tame countries they present most variety when planted so thin as barely to touch each other, and when a number of them are kept low, where the whole are of different ages (fig. 653.) But the variety produced, even by this disposition, is still far short of what would be effected by a similar arrangement of round or oval-

652

headed trees (fig. 654), of different ages, or mixed with shrubs or low growths. The most suitable situation for spiry-topt trees, in ornamental scenery, is as single objects

653

or in small groups (fig. 655.), sparingly introduced in the margin of thickets or strips, or sprinkled along the bottoms of dells or dingles. In plantations which comprise masses of all the different species of hearty tree, there they may come in also in their proper place; and in mountain and rocky scenery, they are in the places which nature seems to have intended for them.
6865. The oblong-headed trees may be introduced much more frequently than the spire-topt sorts; the more obtuse summits blend well with the round-headed trees, and the more acute topt sorts which terminate in flexible flame-like shapes, as the Lombardy poplar, and cypress, form excellent contrasts to the round trees, and serve as transition forms to the spiry tribe. The round-headed trees, it need hardly be observed, are the most general in nature, at least in temperate climates, and are the most universally applicable in ornamental planting. These considerations on the forms of trees refer to them chiefly as in independent plantations; in connection with buildings, the choice, as to form, may often be influenced by that of the building, and also by the effect or object intended by planting them.

6866. With respect to magnitude, the grand division of woody plants is into trees and shrubs. The bulk and heights of the common trees and shrubs of the country being generally known, the eye estimates the magnitude of other objects by theirs; consequently extraordinary magnitudes, whether large or small, should only be used under extraordinary circumstances. The apparent size, proportion, and distance of objects, might otherwise be deranged, and a discordant effect produced. Shrubs, which have the form of trees; and low trees, as the mountain ash, the apple and pear, often produce this effect, when planted as single objects; and unless their fruit is prized above every thing else, they should, when introduced for the sake of their flowers, either be planted in the margins of plantations, or grouped with trees of the ordinary height. The finer small groups are of this description, or composed of common deciduous timber trees and hardy shrubs, as oaks, chestnuts, hollies, thorns, &c.

6867. The choice of species must be made subservient to general effect, and to the particular purposes, for which they have been introduced. They have no use but their mass effect (chap. I.), and both should be continually present in the mind of the planter. For the more general purposes of planting, the standard trees of the country, native or naturalised, are mostly to be preferred, as growing freely and preserving harmony; for the purposes of distinction, foreign trees are more likely to answer the end. Foreign trees also contribute greatly to variety of interest, and therefore are indispensable in pleasure-grounds, or other scenes of much resort. 

Any number of species may be admitted into improved grounds; commencing with the rare sorts near the house, as the centre of art and refinement, and ending with the common trees of the country, at such distances as the extent and style of the which may suggest. The proprietor of the pleasure-ground, and such as are valuable as timber, must be in some degree determined by the character of the place, but chiefly by the taste and view of the owner. Beauty alone, without utility, will not long please; and a few single groups and plants of the choice species, introduced over the grounds more immediately connected to man, will generally afford more satisfaction than a lavish display of exotics; the former will always present a more luxuriant and thrilling display of scenery than the latter, and sooner attain the maturity of beauty. (Edin. Encyc. art. Landscape Gardening.)

6868. Whatever number of species are used, one only should prevail in one place; or if there be high or low growths, then one of each kind should prevail. Great attention should be had that the species which compose the groups and thickets, or other scattered woodinesses which border on masses, should consist of most entire species with peculiar in the masses in this line. This, in this respect neglected, instead of these medleyed productions causing connection and harmony, they will have a tendency directly contrary. Thicket may next be considered in regard to their form, that is, the form of their ground-plan; and with groups and single trees in regard to the choice of species. Thickets are produced by nature, by the inroads of cattle, or other animals, grazing or cropping the herbage, and with the young trees in forest-scenery. On levels and sheltered situations, we find their form comparatively regular, because there appears no permanent or general reason to occasion their encroachment on one side more than on the other. But on varied surfaces and soils a preference is given by degradating animals to certain natural plants, and the side which they frequent deeply than the other; and the plan of the plant and situation varies accordingly. In elevated grounds, exposed to a particular wind, the thickets will exceed in length, which will be found generally to be in the direction of the storm. The cause is too obvious to be pointed out; but this effect, and every other observed in the groups and thickets of natural scenery, always merit study, and most frequently deserve imitation in creations of landscape-scenery. The species of tree ought obviously to be those of the part of the mass to which they belong; for thicket, groups, and single trees, ought to resemble disjointed still more prominent, or increasing the depth of a recess, a few plants of similar, or not discordant growths, but of darker or lighter greens, may at a distance add to the effect of each. By the same process, with more contrasted species, where no other mode can be put in execution, the formality of a single row may in some degree be varied in its situation and contour. (Ed. Encyc. art. Landscape Gardening.)

6869. The arrangement of the species to effect variety must evidently be by grouping or collecting them in masses; for if all the species made use of were intimately mixed together in every part of a plantation, it is evident that we could not see the same species; so that, as far as variation from that source was sought for, it would be entirely wanting. Uvedale Price has treated this subject with much ingenuity; and in reprobating the common practice of mixing as many different sorts as can be procured, in order to produce variety, observes, that variety, of which the true end is to relieve the eye, not to puzzle it, is lost in the diversity of the objects, but in the union of the different objects combined together in a difference of composition and character. Many think, however, that they have obtained that grand object, when they have exhibited in one body all the hard names of the Linnean system. But it is not the number of different species together are exhibited that contributes to novelty; in one plantation, the result is a sameness of a different kind, but not less truly a sameness that would arise from there being no diversity at all; for there is no having variety of character, without a certain distinctness, without certain marked features on which the eye can dwell. (Essays on the Picturesque, vol. I.)

There are there passing from one to another of these trees, the same species not greater than yielding the proportions of a hundred different species, as they are usually mixed together. This indiscriminate mixture of every kind of tree in planting, all variety is destroyed by the excess of variety, whether it is adopted in bosoms or clumps, as they have been technically called; for example, if ten clumps be composed of ten different sorts of trees in each, they become so many things exactly similar; but if each clump consists of the same sort of trees, they become ten different things, of which one may hereafter furnish a group of oaks, another of elms, another of chestnuts or of thorns, &c. In like manner,
in the modern belt, the recurrence and monotony of the same mixture of trees of all the different kinds, through a long drive, make it as more tedious in proportion as it is long. In part of the drive at Weburn, in which evergreens alone prevail, which is a circumstance of grandeur, of variety, of novelty, and, I may add, of winter comfort, that I never saw adopted in any other place on so magnificent a scale, in which the most perfect of pastures, or the wood of evergreens, must be felt the most needful observer; and the same sort of pleasure, though in a weaker degree, would be felt in the course of a drive, if the trees of different kinds were selected in small groups or masses by themselves, instead of being blended indiscriminately.\(^{10}\) (Inquiry into Changes of Taste, &c. p. 53.)

657. We have already recommended the formation of natural forests in the arrangement of the species. In these nature disseminates her plants by scattering their seeds, and the offspring rise round the parent in masses or breadths, depending on a variety of circumstances, but chiefly on the facility with which the seeds afford to a distance by the wind, the rain, or by birds. So disseminated they spring up, different sorts together, affected by various circumstances of soil and situation; and arrive at maturity, containing with other plants and trees, and with the browsing animals. At last, that species which enjoyed a maximum of natural advantages is found to thrive, or at least to gain the market. Trees growing along in masses and in a rank portraiture of surface, the circumstances changing in favor of some other species, that takes the prevalence in its turn. In this way it will generally be found, that the number of species, and the extent and style of the masses in which they prevail, bears a strict analogy to the changes of soil and surface; and this holds good, not only with respect to trees and shrubs, but to plants, grasses, and even the mossy tribe.

657. The most perfect arrangement of species in regard to variety would be to employ every kind of tree and shrub that will grow freely in the air, and arrange them according to the natural system. We have already suggested (614) that a residence might be wooded in this way, so as in the smallest extent to obtain a maximum of variety and beauty. In most cases, where groups of trees, or, some permanent fence is requisite; and all that can be said of it, that which the specimens in the end to be the most efficient and economical, will almost always be the best. The hedge, sunk fence, common wall, and wide water-course where it will be constantly nearly full of water, here present themselves as the most general kinds. Any fence, however, of which the object is, without enclosing anything, should be used with great caution; as there are none of this class but what look ill from at least one point of view, that is, when seen lengthways.

657. In planting in the natural style, a regular fence either of verdant or masonic materials, can never be the final part of perfect imitation, since no such thing is to be found in nature. But in planting in farm-lands, or for the purpose of improving the general scene, or, some permanent fence is requisite; and all that can be said of it, that which the specimens in the end to be the most efficient and economical, will almost always be the best. The hedge, sunk fence, common wall, and wide water-course where it will be constantly nearly full of water, here present themselves as the most general kinds. Any fence, however, of which the object is, without enclosing anything, should be used with great caution; as there are none of this class but what look ill from at least one point of view, that is, when seen lengthways.

657. In planting to form a park or residence, with the exception of the boundary fence, and that which separates the lawn or mown surface from the grazed encenery, no permanent barrier of a formal nature should ever be admitted. In very bleak situations, walls or mounds of earth, however usefully, may be necessary for a time to shelter and draw up the plants; but the final removal of these and all fences in particular to as certain a degree; and indeed, a fence, with rails, the fences conforming to the irregular shapes of the masses will not be disagreable to the eye, if those of the latter are arranged with any regard to apparent connection; for any objects, whether lines or forms, however deficient in beauty of themselves, acquire a degree of interest, and even character, when connected and arranged in such a way as to form a whole. When a plantation is finally to be composed both of trees and undergrowths, thorns, aloes, holies, berberries, and briars, may, in many cases prevail in the margin; which, when the fence is removed, will form a picturesque phalanx, and protect the whole. Partial intrados, formed by cattle, will only heighten the variety and intricacy of such scenes.

657. Sir W. Chambers and Price negroes, as Price observes (Essays, vol. 1.), the planter may plant as thick as he chooses, and never think of thinning or future management, only taking care to introduce no more trees than what he intends to remain finally as timber. The great majority of the plants being shrubs will soon be overtopped by the timber-trees, which, having abundance of water, and well maintained, will quickly get a start of every plant in it, is generally neglected, that this suggestion, under certain circumstances, well merits adoption; though it certainly can have no pretension to be called a scientific or profitable mode of planting. It is what it pretends to be, a picturesque mode.
Of the Culture and Management of Plantations.

6877. On the management of plantations, Pontey and Sang observe, that it is too common a case to consider a tree, when once planted, as done with; though, as every one knows, the progress and products of trees, like those of other plants, may be greatly increased or modified by cultivating the soil, pruning and thinning.

6878. With respect to culture of the soil, it is evident that young plantations should be kept clear of such weeds as have a tendency to smother the plants; and though this is not likely to take place on heaths and barren sites, every one should, at least, every year or two, remove which are conspicuously injurious. In grounds which have been prepared previously to planting, weeding, hoeing by hand, or by the horse-hoe, and digging or ploughing, become necessary according to circumstances. The hoeings are performed in summer to destroy weeds, and render the soil pervious to the air and nourishing for the new growth. It may sometimes be necessary to prepare the soil for spring crops. These, both Pontey and Sang allow, may be occasionally introduced among newly planted trees; though it must not be forgotten that relatively to the trees, the plants composing such crops are weeds, and some of them, as the potatoe, weeds of the most exhausting kind.

6879. For ploughs in manuring, sows go six feet apart, and crops the ground between, with low-growing early potatoes, turnip, lettuce, or other green crops. He does not approve of cropping the intervals with young trees, as a sort of nursery, as they prove more successful crops than excellent vegetables, nor with grain, as not admitting of culture, and being too exhausting for the soil. Marshall, and some other authors, however, approve of sowing the tree-seeds with a crop of grain, and hoeing up the stubble and weeds when the crop is removed.

6880. Pontey observes, that wherever preparing the soil for planting is necessary, that cultivating it for some years after, and then generally be thought the same; for where quick growth is essential, cleanliness of appearance is usually of consequence. Slight crops of potatoes, with short tops, or turnips, may be admitted into such plantations with advantage for two or three years, as they create a necessity for annually digging or stirring the surface, and tend very much to the health of the plants and the crops. It must immoderately enrich the soil, and no doubt but such is the fact, so far as common vegetables are concerned; but as to the production of wood, its support depends, in a great measure, on a different species of nutrient; and hence, I could never observe that such crops as potatos, beets, &c., 

6881. Filling up blanks is one of the first operations that occurs in the culture of plantations next to the general culture of the soil, and the care of the external fences. According to Sang, a forest plantation after pitting, either in the mass form or ordinary mixture, should remain several years after planting, before filling up the vacancies, by the death of the hard-wood plants, takes place. Hard-wood plants, in the first year, and even sometimes in the second year after planting, die down quite to the surface of the ground, and are apparently dead, while their roots, and the wood immediately above them, are quite fresh, and capable of producing very vigorous shoots, which frequently do produce, if allowed to stand in their places. If a tree, such as that above alluded to, be taken out the first or second year after planting, and the place filled up with a fresh plant of the same kind, what happened to the former may probably happen to the latter; and so the period of raising a plant on the spot may be protracted to a great length of time; or it is possible this object may never be gained.

6882. The filling up of the hard wood kinds in a plantation which has been planted after trenching, or summer-fallow which has been kept clean by the hoe, may be done with safety at an earlier period than under the foregoing circumstances; because the trees, in the present case, have greater encouragement to grow vigorously after planting, and may be more easily ascertained to be entirely dead, than where the natural heritage is allowed to grow among them.

6883. But the filling up of larches and pines may take place the first spring after the plantation has been made; because such of these trees as have died are more easily distinguished. In many cases when a larch or fir loses its top, either by dying down, or the biting of hares and rabbits, the most vigorous lateral branch is elevated to the top by degrees, until the branches which the tree has lost have been displaced; Pines and larches, therefore, which have fresh lateral branches, are not to be displaced, although they have lost their tops. Indeed, no tree in the forest, or other plantation, ought to be removed, until there be no room left to hope for its recovery. If the filling up of plantations be left undone till the trees have right and left satisfactory lateral branches are spread far from each other, and ten to twelve feet apart, there will remain a considerable space. The introduction of two or three plants, from a foot to three feet in height, at a particular deficient place, can never, in the above circumstances, be attended with any advantage. Such plants may indeed become bushy, and may answer well enough in the character of underwood, but they will for ever remain unfit for any other purpose. It is highly improper, then, to commence the filling up of hard-wood plantations before the third year after planting; or to prolong it beyond the fifth or the sixth. March is the proper season for this operation. (Plant. Kalden. 285.)

6884. Pruning is the most important operation of tree culture, since on it, in almost every case, depends the ultimate value, and in most cases, the actual bulk of timber produced. In the purposes of pruning, as for most other practical purposes, the division of trees into resinous or frondose-branched trees, and into non-resinous or branchy-headed sorts, is of use. The main object in pruning frondose-branched trees is to produce a trunk with clean bark and sound timber; that in pruning branchy-stemmed trees, is principally to direct the ligneous matter of the tree into the main stem or trunk, and also to produce a clean stem and sound timber, as in the other case. The branches of frondose trees, unless in extraordinary cases, never acquire a timber size, but rot off from the bottom upwards, as the tree advances in height and age; and, therefore, whether pruned or not, the quantity of timber in the form of trunk is the same. The branches of the other division of trees, however, when left to spread out on every side, often acquire a timber-like size; and as the ligneous matter they contain is in general far from being so valuable as when produced in the form of a straight stem, the loss by not pruning off their side branches, or preventing them from acquiring a timber-like size, is evident. On the other hand, when they are broken off by accident, or rot off by being crowded together, the timber of the trunk, though in these cases increased in quantity, is rendered knotty and rotten in quality.
With respect to the manner of pruning, where straight timber is the object, both classes in their infancy, as Sang observes, should be feathered from the bottom upwards, keeping the tops light and spiral, something resembling a young larch. (fig. 657. a) The proportion of their tops should be gradually diminished, year by year, till about their twentieth year, when they should occupy a third part of the height of the plant; this is, if the tree be thirty feet high, the top should be ten feet (b). In all cases in pruning off the branches, the utmost care must be taken not to leave any stumps sticking out, but to cut them in to the quick. It is only by this means that clean timber can be procured for the joiner; or slightly smooth-stemmed trees to please the eye. It is a very general practice to leave stumps or stumps (c); before thebole can be enriched sufficiently to cover these, many years must elapse; the stumps in the meantime become rotten; and the consequence is timber which when sawn up (d) is only fit for fuel. Pontey says, "The sap of a tree may be considered as the raw material furnished by nature; and man, the manufacturer who moulds it into the form most useful for his purpose. A moderate quantity of leaves and small wood is necessary to every tree; but all above that quantity are of no use to the plant, and of little value to its owner." (Forest Pruner, 152, 153.)

Pruning for ornament or beauty must be guided in its operations by what that beauty is. If it is the beauty of art, then the trees may require to be cut or clipped into the shape of animals (fig.345.); or inanimate natural objects, as mounds of earth, mushrooms; or geometric forms, triangles, globes, cones; or walls, columns, arches, vases, arbors, temples, theatres, or other architectural or sculptural compositions. (fig. 658.) The dwarfing of trees is also another kind of artificial beauty, much practised by the Chinese; and though the habit be kept up chiefly by withholding nourishment; yet the dwarf is produced by ringing a branch; enveloping it in a ball of loan; amputating it when it has made roots; and then pinching off all exuberance of growth so as to keep it into shape. (Livingstone, in Hort. Trans. iv. 220.)

"If natural beauty is desired, then the pruning must be rather negative than positive; the object being to let the tree assume its natural shape, or, as Sang describes it, "express its own nature." All that man can do, therefore, in the way of pruning for this object, is to assist a plant of the tree kind to express the characteristics of a tree; that is, a powerful trunk and ample spreading head, which distinguishes it from a shrub; and this he does by clearing a part of the tree's side branches; and by avoiding to train up a shrub with a single stem like a diminutive tree. In attending to these instructions the great importance of the use of leaves must not be lost a sight of: this is not, as Pontey asserts, to attract the sap, but to elaborate it when propellled to them, and thus form the extract or food taken in by the plant, into a fluid analogous to blood, and which is returned so formed by the leaves into the inner bark and soft wood. It must not be a very nice point, but rather, to determine the quantity of branches that should be left on each tree; and if no more are left than what are necessary, then in the case of accidents to them from insects, the progress of the tree will be doubly retarded. Experience alone can determine these things. Both Pontey and Sang agree that "strength is gained as effectually by a few branches to form a head by many." (Forest Pruner, 296.)

The general seasons of pruning are winter and spring, and for the grain midsummer, as it is found to gum very much at any other season. Pontey says, "as to the proper season for pruning, there is only one difficulty; and that is discovered in the wrong one, or the particular time when trees will bleed. Only two trees have been found which bleed uniformly at certain seasons, namely, the sycamore and firs, which bleed as soon as the sap begins to move. In spring pruning, desist when this takes place." As a general rule, he thinks "summer preferable to winter pruning; because, in proportion as wounds are made early they heal so much the more in the same season." (Forest Pruner, 296.)

Sang suspends pruning from the end of February to the middle of July, but carries it on during every other month of the year; the grain, or any other tree very apt to gum, he prunes only in July and August. (Plant. Kal. 268.)

With respect to the implements to be used, Sang observes, "In every case where the knife is capable of lopping off the branch in question, namely, in the pruning of infant plants, it is the only instrument necessary. All other branches should be taken off by the saw. A hatchet, or a chisel, should never be used. Every wound on the stem, or bole, should be quite into the quick, that is, to the level and depth of the bark; nor should the least protruberance be left. The branch to be lopped off by the saw should, in all cases, be notched or slightly cut on the under side, in order to prevent the bark from being torn in the fall; and when the branch has been removed, the edges of the wound, if anywise ragged, should be pared smooth with the knife. If the tree be vigorous, nature will soon cover the wound over with bark, without the addition of any plaster to exclude the air. In the shortening of a strong branch, the position of which is pretty upright, it should be observed to draw the saw obliquely across it, in such a manner as that the face of the wound shall be incapable of retaining moisture; and afterwards to smooth the edges of the bark with the knife." (Plant. Kal. 181.) In every case where
the branches are too large for the knife, Pontey prefers the saw, as the best and most expeditious instrument; and one, the use of which is more easily acquired by a laborer than that of either the bill or axe. In "large work" he uses the common carpenter's saw; for smaller branches, one with somewhat finer teeth, with the plate of steel, and about twenty inches long. Having stated what is general in pruning, the next thing is to submit some particular applications of the art to resinous and non-resinous timber-trees, copse-woods, osier-holts, hedges, and hedge-rows, and trees in parks.

6929. Resinous trees, Pontey and Sang agree, should not be pruned at so early an age as the non-resinous kinds. Sang commences about the sixth or eighth year, according to their strength or vigor, and resomes or removes one or two lower branches when the plant has got to a certain height, gives the first pruning by "displacing two or at most three tiers of the lower branches; after which, intervals of three years might elapse between the prunings; never displacing more than two tiers at once, except more shall prove dead." (Forest Pruner, 50.) Sang judiciously observes, "Excessive pruning, either of the tree, or of any one of its branches, is highly injurious, not only to the health of the plant, but to the perfection of the wood. If a sufficient number of branches are not left on the young plant to produce abundance of leaves, perfectly to concoct its juice, the timber will be loose in its texture, and liable tozechial decay." The opinion of Nicoll and Monteath are at variance, with those of Pontey and Sang, as to pruning resinous trees. Nicol advises leaving snags (Pract. Plant. 213), and Monteath (For. Guide, 45.) says, "Never cut off a branch till it has begun to rot, as the bleeding of a live branch will go far to kill the tree.

Non-resinous trees, Sang observes, "should be pruned betimes, or rather from their infancy, and thenceforward at intervals of one or at most two years. If the pruning of young forest-trees is performed only at intervals of eight or ten years, the growth is unnecessarily thrown away, and wounds are inflicted which will ever after remain blemishes in the timber; whereas, if the superfluous, or competing branches had or might have been removed, not only would every blemish be avoided, but the growth of the plant would be imperceptible, or at least not hurtful to the timber, when it came to the hands of the artist.

The pruning of all deciduous trees should be begun at the top, or at least those branches which are to be removed or shortened. Having first selected what may for the time be considered as a leader, or shoot for a leader, or that by which the stem is most evidently to be elongated and enlarged, every other branch on the plant should be rendered subservient to it, either by removing them instantly, or by shortening them. Where a plant has branched into two or more rival stems, and there are no other very strong or straight ones, then simply allow the whole the greatest liberty, than by the bore, leaving only the strongest and most promising shoots. If three or four shoots or branches be contending for the ascendancy, they should, in like manner, be lopped off, leaving only the most promising. If any of the branches which have been left further down on the bole of the plant at former prunings have become very strong, or have extended their extremities far, they should either be taken clean off by the bore, or be shortened at a proper distance from it; observing always to shorten at a lateral twig of considerable length. It is of importance that the tree be equally poised; and therefore if it have stronger branches than the others, they should either be removed or heavily pruned, or if pruned, properly trained, under twenty feet in height, should appear light and spiral, from within a yard or two of the ground to the upper extremity; its stem being furnished with a moderate number of twigs and small branches, in order to retain the sap, and circulate it more equally through the plant. Trees of this size, or very large ones, if they are properly formed, will remain much longer, and go on in their growth, without any subsequent pruning will mostly consist in keeping their leading shoots single. From the want of air, their lateral branches will not be allowed to extend, but will remain as twigs upon the stem. These, however, frequently become dead branches; and if such were allowed to remain at all on the trees, they would naturally be cut away, to diminish the blemishes and injurious value of the timber; hence the propriety of allowing any branch to die on the bole of a tree; indeed, all branches should be removed when they are alive; such a method, to our knowledge, being the only sure one to make good timber.

From these circumstances, an annual pruning, or at least an annual examination, of all forests, is necessary." (Plant. Kal. 180.)

6994. Heading down such non-resinous trees as stole we have already (6829.) stated to be an important operation. After the trees have been three or four years planted, Sang directs that such as have not begun to grow freely should be headed down to within three or four inches of the ground. The cut must be made with the pruning-knife, Sang says, in a sloping direction, with one effort. Great care should be taken not to bend over the tree in the act of cutting. By so bending, the root may be split, a thing which too often happens. The operation should be performed in March, and not at an earlier period of the season, because the wounded part might receive much injury from the severe weather in January and February, and the expected shoot be thereby prevented from rising so strong and vigorous. (Plant. Kalend. 297.) Buffon, in a memorial on the culture of woods, presented to the French government in 1742, says he has repeated this experiment so often, that he considers it as the most useful practice he knows in the culture of woods.

6985. For the purpose of producing bends for ship-timber, various kinds of pruning have been proposed. According to Pontey, "little is hazarded by pruning, if plenty of long, clean, straight, free-grained pieces could be got, boiling and a screw apparatus would form bends." Monteath, a timber valuator of great experience, and in extensive practice, says, the value of the oak, the broad-leaved elm, and Spanish chestnut, depends a good deal on their being crooked, as they are all used in ship-building. The same has seen trees successfully trained into crooked shapes of great value, in the following manner: "If you have an oak, an elm, or chestnut, that has two stems, as it were, striving for the superiority, lop or prune the straightest; and if a tree that is not likely to be of so much value be standing on that side, to which the second is likely to extend, cut away its highest shoots, and they will perhaps fairly divide every chance of growing horizontally. At this time it will be necessary to take away a few of the perpendicular shoots off the horizontal branch; and, indeed, if these branches, which is sometimes the case in these trees, extend more than twenty feet out of the tree, and if this tree be of a sufficient size, and if the two of these trees over-much, except the crooked shoots on the horizontal branch, till they arrive at the height of fifteen or even twenty feet. By this time it will be easily seen what kind of tree it is likely to form; and, if it inclines to grow crooked, lighten a little the top of the tree, by taking off a few of the crooked branches, and some of the branches to remain of those which are straight or nearly so, to give it more weight, and to draw most of the sap or juice that way, and it will naturally incline more to the crook; at the same time clearing away any other tree on the crooked side, that may be apt, with the wind, to whip the side of the tree to which it inclines to crook, also taking away such tree of least value as may prevent growth spreading out to the one side more than to the other." He adds,
CULTURE, &c. OF PLANTATIONS.

961

"I have myself tried the experiment with several oak-trees at about twelve feet high that were a little inclined to crook, and that had also a main branch inclined to a horizontal position. In the course of less than twenty years I had the pleasure of seeing some of these very trees grow so very crooked that the branch would work in with the main stem or body of the tree, to a complete knee, or square, which is the most valuable of all trees. And as ten trees of crooked oak are required for one straight one, it is of the most essential consequence to have crooked oak-trees; and, besides, an oak-tree, properly crooked, that will answer for a large knee — say the main branch, to be fit to work in with the body or trunk of the tree without much waste of wood, is nearly double in value to the same number of straight trees; and, indeed, knees of oak are extremely scarce, and difficult to get." 6897. Coppice-woods, in so far as grown for poles or bark, require pruning on the same principle as timber trees, in order to modify the ligneous matter into stem, and produce clean bark. In as far as they are grown for fence-wood, fuel, or besom-spray, no pruning is required.

6898. Oister-holls only require the laterals to be pinched off the shoots intended for hoope; those for the basket-maker seldom produce any. The stools also require to be kept free from dead wood and stinted knotty protuberances.

6899. Hedge-rows require side pruning, or switching, from their first planting, so as gradually to mould them into "the wedge shape, tapering from bottom to top on both sides equally, till they meet in a point at the top. Two feet at bottom is a sufficient breadth for a five-feet hedge: a greater or a less height should have the bottom wider or narrower accordingly. In dressing young hedges, either of the deciduous or evergreen kinds, the sides only should be cut till the hedge arrive at the proposed height, unless it be necessary, for the sake of shelter, to cut their tops over, in order to make the hedge thicker of branches. Such cutting of the upright shoots, however, is not of any very great use in this respect; because every hawthorn-hedge sends out a number of side shoots, which, if encouraged, by keeping the top narrow as above, will make it abundantly thick." (Sang, 447.) In pruning hedges, some use shears; but the hedge-bill (fig. 115.) is the most proper instrument, and prunes a smooth unfractured section, not so apt to throw out a number of small useless shoots as generally follow the bruised cut of the shears. (fig. 125.)

6900. Hedge-row trees require to be pruned to a tall, erect, clean stem, as at once producing more timber and doing least injury to the ground under their drip and shade.

6901. Trees in strips for shelter, or screens for concealment, ought to be furnished with branches from the bottom upwards; unless undergrowth supply this deficiency. Where this is not the case, care should be had that the trees be pruned into conical shapes, so as that the lower branches may be as little as possible excluded from the influence of the weather by the upper ones.

6902. Trees for shade, where shelter from winds is not wanting, should be pruned to ample spreading heads with naked stems; the stems should be of such a height that the sun’s rays, at mid-day, in mid-summer, may not fall within some yards of the base of the trunk; thus leaving, under the tree, as well as on its shady side, a space for the repose of men or cattle.

6903. Trees in parks may be considered as chiefly ornamental; and for this purpose should be left with larger heads than such as are grown chiefly for timber. The height to which the stems are cleared of branches should vary according to the kind of tree (fig. 659. a to e); and hollies, thorns, and such shrubs as are left untouched, or that are protected by enclosure from the cropping of cattle (fig. g), should be left entirely to themselves. In parks, where no pruning whatever is given to the timber-trees by man, we find they are all pruned or browsed to a certain height by cattle: this adds to their character as trees, but in flat surfaces forms a disagreeable repetition of the horizontal line in which they stand. To break this browsing line, pruning is a simple, obvious, and effectual resource.

6904. Some trees in pleasure-grounds and lawns, where no cattle ever come, may be allowed to extend their branches so as they may almost recline on the turf; others may be pruned to different heights, according to their uses. Limes, planees, cedars, and fir have a fine effect with their branches depending from their trunks; and give an idea of seclusion and exclusive consecration to man, highly characteristic of what is called pleasure-ground.

6905. The properly thinning out of plantations, Sang observes, "is a matter of the first importance in their culture. However much attention be paid to the article of pruning, if the plantation be left too thick, it will be inevitably ruined." A circulation of air, neither too great nor too small, is essential to the welfare of the whole. This should not be wanting at any period of the growth of the plantation; but, in cases where it has been prevented by neglect, it should not be admitted all at once, or suddenly. Opening a plantation too much at once, is a sure way to destroy its health and vigor. In
thinning, the consideration which should in all cases predominate, is to cut for the good of the timber left, disregarding the value of the thinnings. For, if we have it in our choice to leave a good, and take away a bad plant or kind, and if it be necessary that one of the two should fall, the only question should be, by leaving which of them shall we do most justice to the laudable intention of raising excellent and full-sized timber for the benefit of ourselves and of posterity? The worst tree should never be left, but with the view of filling up an accidental vacancy."

6906. In thinning mixed plantations, the removing of the nurses is the first object which generally claims attention. This, however, should be cautiously performed; otherwise the intention of nourishing, after all, be thwarted. If the situation be much exposed, it will be prudent to retain more nurses, although the plantation itself be rather crowded, than where the situation is sheltered. It is possible, however, some will be lost or which the planters have to be sacrificed for timber crop; and for this reason, in bleak situations, and when perhaps particular nurse-plants can hardly be spared, it may sometimes be necessary to prune off the branches from one side entirely. At subsequent thinnings, such pruned or disfigured plants are first to be removed; and as to those which, through the injury of the age, the age, the plantation all the nurses are to be removed, cannot easily be determined; and, indeed, if the nurses chiefly consist of larches, it may with propriety be said, that they should never be totally removed, while any of the other kinds remain. For, besides that this plan is admirably calculated to compose a partial of agreeable mixture, it is excelled by few kinds, perhaps by none, as a timber-tree.

6907. But when the nurses consist of inferior kinds, such as the mountain ash and the Scots pine, they should generally be all removed by the time that the plantation arrives at the height of fifteen or twenty feet, in order that their, by their means, be drawn up too weak and slender. Before this time, it may probably be necessary to thin out a part of the other kinds. The least valuable, and the last thriving plants, should first be condemned, provided their removal occasion no blank or chasm; but where this would happen, they should be kept back till the others, provided to stand till full-grown; which of the kinds the soil seems best fitted for; whether the ground be flat or elevated; and whether the ground be exposed or sheltered, are all circumstances which must influence the determination of the ultimate distance at which the trees are to stand. It may, however, be said in general, that if trees are to be allowed, a distance of from twenty to thirty feet, according to their kinds and manner of growth, they will have room enough to become larger timber.

6908. With respect to the final distance to which trees standing in a mixed plantation should be thinned, it is hardly possible to prescribe fixed rules; circumstances of health, vigor, the spreading nature of the tree, and the like, must determine. Whether the trees are to be suffered to stand till full-grown, or, which of the kinds the soil seems best fitted for; whether the ground be flat or elevated; and whether the ground be exposed or sheltered, are all circumstances which must influence the determination of the ultimate distance at which the trees are to stand. It may, however, be said in general, that if trees are to be allowed, a distance of from twenty to thirty feet, according to their kinds and manner of growth, they will have room enough to become larger timber.

6909. Plantations of Scots pine, if the plants have been put in at three or three and a half feet apart, will require little care until the trees be ten or twelve feet high, in order that the trees may tower the faster, and push fewer and weaker side branches. Indeed, a fir or soft wood plantation should be kept thicker at any period of its growth than any of those consisting of hard wood and nurses already mentioned; and it may sometimes be proper to prune up certain plants as nurses, as hinted above, for nurses, as a mixed plantation. Those pruned up trees are of course to be reckoned temporary plants, and are afterwards to be the first thinned out: next to these, all plants which have lost their leaders by accident should be condemned; because such will never regain them so far as afterwards the same stately timber, provided that the nurse-plants have not been left in their place, to form the shaded material blanket of the plantation. Care should be taken to prevent winds; nor should the plantation be thinned much at any one time, lest havoc be made by prevailing winds; an evil which many, through inadvertency, have thus incurred. This precaution seems the more necessary, inasmuch as Scots pineapple is intended for useful timber, and all trees, except to be reserved, except in order to be reserved for their situation, may be thinned of, and small, thin and soft. At forty years of age, a good medium distance for the trees may be about fifteen feet every way. It may be worthy of remark, however, that after a certain period, perhaps by the time that the plantation arrives at the age of fifty or sixty years, it will be proper to prune more frequently, to harden the timber; and that, form, this may be done with less risk of danger, from the strength of the trees will have acquired, than at an earlier period; but still it should be done gradually.

6910. Plantations of spruce and silver firs, intended for large useful timber, should be kept much in the manner above stated, both in their infancy and middle age. As already remarked, planting and keeping them as thick as is consistent with their health, is the best means of producing tall, straight, clean stems, and valuable timber. When planted for screens or for ornament, they require a different treatment, which will be noticed in the proper place.

6912. The proper seasons for thinning are autumn, or very early in spring, where the trees are to be taken up by the root and replanted elsewhere; and winter for thinning for timber and fuel; but such trees as are valuable for their bark should be left untouched till the sap rises in April or May. Copse-woods require thinning when young, like other plantations, and when once established the stools require to be gone over the second year after cutting; and all superfluous suckers and shoots removed. This operation should be repeated annually, or every two or three years, with pruning, till within three or four years of the general fall of the crop.

6913. Ornamental plantations require to be thinned on principles agreeable to the intention with which they were planted. In the artificial forms, the figure must be carefully preserved, as the main object; and in plantations in imitation of nature, the principle of grouping and connection must be kept steadily in view. A thin part is to be rendered thinner, and a thick group, or constellation of plants not opened up, but merely deprived of such trees as are becoming smothered by the rest.
6914. Improving neglected plantations. Though it has been more or less fashionable, for upwards of a century, to form plantations; yet it has been also so generally the custom to neglect their future culture, that by far the greater proportion of the surface covered with trees in Britain may be considered as neglected or mismanaged. The artificial strips and masses have generally never been thinned or pruned; and the natural woods and copse-woods improperly thinned, or cut over. It is often a difficult matter to make much of such cases; and always a work of considerable time. "Trees," Sang observes, "however hard their natures may be, which have been reared in a thick plantation, and consequently have been very much sheltered, have, their natures so far changed, that if they be suddenly exposed to a circulation of air, which under different circumstances, would have been salubrious and useful to them, will become sickly and die. Hence the necessity of admitting the air to circulate freely among trees in a thick plantation, only gradually and with great caution. To prevent a misfortune of this kind, a plantation which has become close and crowded, having been neglected from the time of planting till perhaps its twentieth year, should have only some of the smallest and most unsightly plants removed: one perhaps, in every six or eight, in the first season; in the following season, a like number may be removed; and in two or three years after, it should be gone over again, and so on, till it be sufficiently thinned. It will be proper to commence the thinning, as above, at the interior of the plantation, leaving the skirts thicker till the last; indeed, the thinning of the skirts of such a plantation should be protracted to a great length of time." With thinning, pruning to a certain extent should also be carried on. "If the plantation," Sang observes, "consists of pines and firs, all the rotten stumps, decayed branches, and the like, must be cut off close by the bole. It will be needful, however, to be cautious not to inflict too many wounds upon the tree in one season; the removing of these, therefore, should be the work of two or three years, rather than endanger the health of the plantation. After the removal of these from the boles of the firs and larches, proceed every two or three years, but with a sparing hand, to displace one or perhaps two tiers of the lowermost live branches, as circumstances may direct; being careful to cut close by the trunk, as above noticed. In a plantation of hard wood, under the above circumstances, the trees left for the ultimate crop are not to be pruned so much as at first as might otherwise be required; only one or two of their competing branches are to be taken away, and even these with caution. If it be judged too much for the first operation to remove them entirely, they may be thinned, to prevent the progress of the competition; and the remaining parts may be removed in the following season; at which time, as often observed, they must be cut close by the bole." (Plant. Kal. 467.)

6915. The operation of thinning and pruning, thickening or filling up, or renewing portions that cannot be profitably recovered, should thus go on year after year, as appearances may direct, on the general principles of tree culture. And for this purpose the attentive observation and reflection of a judicious manager will be worth more than directions which must be given with so much latitude. Pontey has noticed various errors in Kennedy's Treatise on Planting, and even in Sang's Kalendar, on the simple subject of the distances, which he considered in these cases, which had never come within their experience. "Most people," he says, "take it for granted, that if trees stand three feet apart, they have only to take out the half, to make the distances six feet, though to do that, they must take down three times as many as they leave. By the same rule again, most people would suppose, that twelve feet distance was only the double of six; but the square of the latter is only thirty-six, and that of the former one hundred and forty-four, or four times the latter; so that to bring six feet distances to twelve, three trees must be removed for every one left." (Profitable Planter, 556.; Forest Primer, 21.)

6916. Copse-woods are sometimes improved by turning them into woods, which requires nothing more than a judicious selection and reservation of those shoots from the stools which are strongest, and which spring more immediately from the collar. But a greater improvement of copse-woods consists in cutting over the overgrown and protuberant stumps, by the surface of the soil. Fig. 690, a, b, c, d, e, &c., may be replaced, as has been found by Montaub completely to regenerate them. The operation is performed with a saw, in a slanting direction, and the young shoots being afterwards properly thinned, soon establish themselves securely on the circumference of large, and perhaps, rotten-hearted roots. (Forester's Guide, 60.)

6917. Hedge-rows are often neglected, and, like larger plantations, require renovation by cutting down and filling in vacancies, and by cultivating the soil at their roots. Hedges, Sang observes, which have been long neglected, shoot up to a great height like trees, become naked at bottom, and occupy too much ground, at least for lands in a state of high cultivation. The best method of reducing such to a proper size, and of forming them into an immediate fence, is by plashing.

6918. Plashing. This consists in selecting the strongest and straightest shoots. These are to be dressed up and headed down to four feet, and in such a way that the tops of the whole may range in a neat line. These are called the stakes; and, when they are deficient, either in strength or number, recourse must be had to artificial stakes, which must be driven in to stand firm, and supply the deficiency of natural ones. Having proceeded thus far in preparing the hedge for plashing, the hedger is to begin.
at one end, and bend down as close as possible the remaining pliable branches, crossing them in the manner of basket-work. Such as are too strong to be bent, may be cut half through with the bill, which will render them pliable enough to be used; and such as are not required for any of the above-mentioned purposes, must be cut off close to the ground. After the plashing is finished, the hedge should be dressed smooth on both sides by the switching-bill or shears. There is another method of plashing, which has been suggested as an improvement upon the foregoing; and that is, by not cutting any of the stems over as stakes, but weaving in the tops along with the other branches. This method will not have so immediate a tendency to bare the lower parts of the hedge by the growth of the top, as when any of the plants are cut over for stakes; but still, at the bendings, the growth will rush out with vigor; besides this plan is attended with more labor. Indeed, the best security against baring the bottom of a plashed hedge, is by cutting over by the surface as many of the plants as can be at all spared; and the shoots arising from these will soon thicken the hedge at bottom. Plashing can only be effectually and handsomely performed, when there is a good portion of long, pliable, and well feathered branches, and where the hedge has, if not youth, at least vigor, on its side. After the plashing is completed, the ditch is to be scoured out, and the bottom of the hedge cleaned and dressed up, in the same neat manner as if all were new work.

6649. Cutting over old hedges is a much less expensive method of reclaiming or renewing, than any of the above; and, properly performed, may be a more eligible one; saving when an immediate fence is the object. In cutting down an old hedge, there is certainly a very fit opportunity of laying the foundation of a complete and durable fence. The nature of the cutting must be regulated by circumstances, according to the age, the strength, or the closeness of the hedge, and whether it have been planted in single or double rows. If a hedge in question be pretty vigorous and branching towards the bottom, and if the stems stand regularly and closely together, it may be brought into due subjection, without being cut down to the ground. In this case, the sides are first to be switched up with the hook, not altogether close to the stems, but within about a foot or two on each side at bottom, tapering up close at top, which should be four or five feet high, according to the general height of the hedge; but if the hedge be thin at bottom, it will be advisable to cut more in, in order to make it bushy from the ground upwards. If the hedge is not regularly close from end to end, but ragged, and full of gaps, the best method is to cut it over, within eight or ten inches of the ground, and to fill up the gaps with stout well rooted plants of the same kind; or the gaps may be mended by the following method: — Let one of the stoutest thorn-plants next to the gap be reserved uncut, and the space be digged over, or it may require to be filled up with rich earth to within three inches of the height of the top of the ditch. Then having cleaned the thorn-plant of all side branches or twigs, cut it half through at the height of the earth in the gap, on the side farthest from it, and lay it down upon the earth, securing the most distant end from rising up by a hooked pin; then cover it all over with rich earth, so as to make it the general height of the top of the ditch: and the thorn-plant so laid down and covered, will take root, and send up a profusion of shoots over its whole length. If one plant will not reach the whole extent of the gap, one at each side probably will. The surface of the bank should be pointed up, and the ditch scoured as above directed in plashing.

6650. In other cases, when the hedge is getting thin below or too tall, and when the stems are placed regularly within eight or ten inches of one another, and where it is necessary to retain a fence and at the same time to cut so as to have a supply of young shoots from the bottom, the plan to be followed is to cut alternately the one part to within eight or ten inches of the bottom, and the other at four feet high, dressing the bank and securing the ditch, as directed above. In cases where two rows of quicks have been planted, the front one is to be cut by the surface, and the other at four or five feet high, as circumstances may require.

6691. Neglected hedge-row timber may be improved by pruning according to its age. Blakey recommends what he calls foreshortening, or cutting in, as the best method both for young and old hedge-row timber. "This operation is performed by shortening the over-luxuriant side branches (fig. 661. a), but not to cut them to a stump, as in snag pruning; on the contrary, the top only of the branch should be cut off, and the amputation effected immediately above where an auxiliary side shoot springs from the branch on which the operation is to be performed (b); this may be at the distance of two, four, or any other number of feet from the stem of the tree; and suppose the auxiliary branch which is left (when the top of the branch is cut off) is also over-luxuriant, or looks unsightly, it should also be shortened at its sub-auxiliary branch, in the same manner as before described. The branches of trees pruned in this manner are always kept within due bounds; they do not extend over the adjoining land to the injury of the occupier, at least, not until the stem of the tree rises to a height out of the reach of pruning, when the top branches can do comparatively little injury to the land. By adopting this system of pruning, the bad effects of close pruning on old trees, and snag pruning on young ones, will be avoided; the country will be ornamented; and the community at large, as well as individuals, benefited."
CULTURE, &c. OF PLANTATIONS.

6922. Hedge-rows frequently require to be altered in direction to improve the form, or increase the contents of farm-enclosures. (fig. 662.) Generally, and especially in flat arable lands, this is done by eradicating such as are in unsuitable directions (a), and substituting others (b) in parallel, or at least in straight lines; but in rising grounds, and where the surface will be improved by shelter, it frequently happens that a crooked hedge is superseded by two straight ones, and the interval (c) filled up with plantation. The advantage of straight-lined fields to a farmer is very considerable; and when this object is procured in the latter way, an improvement is produced both useful and ornamental.

6923. Ornamental plantations are no less frequently neglected than such as are considered chiefly useful. Clumps, belts, and screens which have become thin, because they have not been thinned, are almost every where to be met with. "In those neglected plantations," says Lord Meadowbank, "where daylight may be seen for miles, through naked stems, chilled and contracted by the cold, the mischief might, perhaps, be partially remedied, by planting young trees round the extremities, which having room to spread luxuriantly, would exclude the winds, and the internal spaces might be thickened up with oak, silver fir, beeches, and such other trees as thrive with a small portion of light. When once the wind is excluded, the weakest of the old trees might be taken out, and the others left to profit by the shelter and space that is afforded."

One of the most hopeless cases of improvement in this department is that of an old clump of Scotch pines (fig. 663), from which scarcely any trees can be taken without risking the failure of the remainder. The only way is to add to it, either by some scattered groups in one direction, or in various directions. Where a clump consists of hard wood, either entirely or in part, it may sometimes, if effect permits, be reduced to a group, by gradually reducing the number of the trees. The group left should be composed of two or three trees of at least two species, different in bulk, and somewhat in habit, in order that the combined mass may not have the formality of the clump.

6924. Scattered trees in ornamental scenery otherwise of very good shapes, and very well managed as to pruning, destroying the browsing line, &c. individually, are often, from want of thinning in some places, and thickening in others, deficient in massiness (fig. 664); the obvious remedy is to thin out some (a), and plant others, so as to destroy the straggling non-cooperating appearance which such trees present, and produce something of grouping, massiveness, and character. (fig. 665.)

6925. Wounds, bruises, casualties, and defects of trees. Small wounds, such as are required to be made by judicious pruning, easily heal up of themselves; large wounds, by amputations of branches, above six inches' diameter, should, if possible, never be made. Even wounds of six inches' diameter, or under, will heal quicker by the application of any material which excludes the air and preserves the wood from corruption; and we agree with Sang, in recommending coal-tar, or the liquor produced from coals
in manufacturing gas. It is, however, less favorable to the progress of the bark over the wound than a coating of clay or cow-dung, covered with moss to keep it moist. Ponkey recommends putty and two coats of paint over it. In case the wood, at a bruised or amputated place, have by neglect become already corrupted, the rotten or dead wood is to be pared out quite into the quick; and the wound is then to be dressed with tar, or clay covered with a piece of mat, sacking, or moss. A wound, hollowed out as above, may at first appear an unsightly blench; but, in subsequent years, nature will lay the coats of wood, under the new-formed bark, thicker at that place; and probably may, in time, fill it up to be even with the general surface of the tree.

928. All fractures, by whatever means produced, are to be managed as the circumstances of the case require. If a large branch be broken off at the middle of its length, it should be sawn clear off close by the lateral which is nearest to thebole of the tree: but, if there is no lateral, or branch, capable to carry forward the growth, cut the main or fractured branch in quite to the bole. In both cases, treat the wounds as above recommended.

929. Desiccating, arising from the dampness of the soil, cannot by the art of man be cured; though it might have been prevented by timeous draining. The hearts of trees frequently rot, where there is no excess of moisture, and especially such as have been produced from old roots left in the ground by a previous felling. Such roots, when in good ground, send up very great shoots with few leaves in proportion to their sizes; by the absence of a profusion of these, properly to conceal the juices so abundantly supplied by the roots, the fibre of the wood is loose and imperfect; the next season will supply more leaves in proportion to the supply of juices, yet not a sufficient number for carrying perfect timber; several years may pass before this event arrive; thus crude and ill digested timber disposed to premature decay, is the foundation over which subsequent coatings of wood are laid: yet, however perfect these may be, they do not prevent the progress of decomposition going on in the interior. Nature teaches how necessary numerous old trees are to the proportion of the solid wood; the cotedelles, and subsequent leaves, are more or less intermixed, and are covered with the solid contents of the first year's shoots from roots like the above.

928. Shakes often arise from the weight and multiplication of top branches, and might have been prevented by timeous pruning. Shall be ascribed to the holes of trees, however, often happen where there is no absence of too much moisture. Sometimes the rains running down from the branches, wets one part of the bole, while the rest is comparatively dry. If this circumstance is succeeded by an intense frost, before the wetted side becomes dry, the bole may be rent for a great length, and perhaps to the depth of the shakes or repairs. To be like to cure. The best method of helping them, is to trace out their upper extremity, caulk it up with oak, and pitch it over, to prevent the rain descending that way in future. (Sang.)

929. In cases of hollowness, Ponkey recommends probing to the bottom, letting out the water, if any, with an auger, drying the cavity with a cloth, filling it with dry sand, plugging it with wood and oakum, and then painting it over.

930. Deciscated stems or branches by lightning, or otherwise, if the soft wood is not much injured, will heal over and become covered with bark; and this the more certainly and rapidly if the air be excluded by a coating of adhesive matter, as cow-dung and quick-lime, or taying on moss or bandages of mat or oakum. Ponkey gives an instance in which such a method was successful in the case of an apple-tree. (Pruner, 230.) We have witnessed it on an extensive scale on the trunk of a pear-tree; and we are informed, on the best authority, of other cases now under progress, in the government garden of the Luxembourg at Paris, as matter of experiment, by Du Thuars, an most ingenious physiologist.

931. Withered or decayed tops may arise from age and incipient decay; but also, as Ponkey states, from improper pruning, or the want of it. We often see it from improper pruning of elms, which, after having been cut down to their summits for many years, are left entirely to nature; in that case they branch out luxuriantly below, and the top withers. By neglecting to thin out the branches on the stems of non-resinous trees, the same effect may be produced.

932. Stunted tops and branches, of constant nourishment; on very tall naked stems it is from these circumstances; and on short stems from defects in the soil. Oblquely placed misshapen heads, in detached trees, commonly proceed from the same causes and want of shelter. Stinted growth, both in tops and stems, is also produced by ivy, and by when young mosses, the caterpillar, and other parasites. Ivy commonly is the principal cause of its expansion, as well as excludes air and moisture, by which the outer bark becomes rigid and corky. Happily, both men and trees will live a long time under the influence both of deformity and disease.

933. Excessive exudations of gum and resins are peculiar to resinous and some other trees when over-pruned, or pruned at improper times. Mildew, honeydew, and blight, three popular names applied to the effects of certain insects of the aphid kind, attack the oak, beech, poplar, and many trees; all that can be said is, if proper regimens has been regularly attended to, trees will overcome these and all other enemies.

934. Insects and vermin. Almost every tree has its particular insect of the hemipterous and dipterous families, and many of the coleoptera family are common to all. The foliage of the small-leaved elm of hedges is often almost entirely destitute; in the early part of the season by touthredine; and those of the larch and Scotch pine have suffered materially in some seasons from aphides The Aphis laricæ, L. (Eriosoma of Leach) increased to an alarming extent from 1800 to 1892, on the larch, on account of three dry seasons following each other; but, though it retarded their growth, it ultimately destroyed very little. Sprague says it has known to increase since 1783; that it destroys more than injures the tree, and is now (189) thought little of. Indeed, almost every species of tree has been known to have suffered in some one or more seasons, and in particular districts from insects; for which, on so large a scale, there seems to be no applicable remedy but patiently waiting till their excess, or the increase of other vermin or insects, succeeds in attaining that extent. The hares, properly cultivated and managed, generally overcome such enemies. The hare is well known to be very injurious to young trees, and especially to laburnums, by gnawing off their bark. Coating their stems with dung and vinegar, or running from the cow's rumen, it may be poisoned with a brush about two feet high brushwood, laden with forage, for a hundred trees, with stems of three or four inches in diameter; and its virtue, after laid on, endures at least two years. (Bull, in Caled. Hort. Mem. iv. 190.)
6935. Of the various products afforded by trees, the first is their leaves, which are or may be collected in close plantations for the sake of the manure they afford; and in open groves, parks, and lawns, for that purpose, and to prevent their injuring the grassy surface. Leaves are also gathered on the continent as food for cattle. Though, at first consideration, leaves would appear to benefit pastures by sheltering the roots of the grass during winter, and afterwards rotting into manure; yet experience proves, that in considerable quantities they impede the growth of the grass plants, by bringing on decay at their roots, in all probability owing to their exclusion of air. For this purpose, in well wooded parks, the leaves are carefully collected in the beginning of winter, and carried to roo-heaps in secluded situations, where in two years from the time of gathering, they become the valuable mould so much in demand by the gardener. A very ingenious machine for sweeping together, and at the same time lifting up leaves into a box or receiver, has been invented by Snowdon, a London machinist, and has been partially in use in Windsors Forest and at Hampton Court; it is also calculated for cutting or raking off weeds, as clean-cut weeds are found to grow again, the same season, while the roots of the others often rot,) or mowing and lifting the weeds or swarth into the cart; but it is not yet sufficiently matured to enable us to describe it as completely answering all its intended purposes. Great credit, however, is due to the ingenious inventor, who has been occupied on it for upwards of two years, and who has spared neither time nor money.

6936. Prunings or spray are the next product of trees; those which they afford at a very early period, and all clippings of hedges or artificial forms, are only fit to be used as leaves; the larger prunings may be used for some of the various purposes to which copse-wood and the top of trees are applied. On the continent, and especially in Sweden and Denmark, spray is annually collected and sacked for the use of cattle in winter. This was also the practice of the Romans, who preferred the spray of the elm, as the Swedes do that of the birch.

6937. The thinings, when not beyond a suitable age, and taken up properly (6905.) and at a proper season, may be replanted in other situations, as single trees and groups; or they may be used as hedges, hop-poles, poles for garden-training, for fencing, for props in coalesiers, and for a great variety of purposes; those whose branches are useful for tannin should not be cut down or rooted up till May, but the others at any time during winter. It is common to sort them into lots, according to their kind or size, and to baggot up the spray for fuel, besom-stuff, or for distilling for bleachers' liquor. See Copse-woods.

6938. The seeds of trees in general cannot be considered of much use beyond that of enriching the species, and in very particular instances, where it is desired a tree should attain bulk as rapidly as possible, the flowers should be pinched off as they appear. The seeds of the oak, beech, and sweet chestnut, however, are valuable for feeding swine, and where they abound may either be swept together after they drop, and carried away and preserved dry in lofts for that purpose; or if other circumstances are favorable, either driven under the trees to collect them. These, and other seeds, as the hawk and holly, are also eaten by deer. The seeds of the trees mentioned, and of all the resinous tribe, are in general demand by the nurserymen for the purposes of propagation. The seeds of almost all other trees and shrubs are also gathered for medicinal or ornamental purposes, or may be collected for the purpose of distilling. Some are collected in the season, and are to be collected in the end of autumn or beginning of winter, with the exception of a few, such as the elm, poplar, willow, and one or two others, which ripen their seeds in May or June.

6939. In osier-grounds, willows, whether intended for the basket-maker or cooper, should not be cut till the second season after planting, in order to strengthen the stools; but by the third autumn the crop will be fit for the basket-maker, and the fourth plantations intended for the cooper (hoops requiring the growth of two years) will be ready. The seasons for cutting are November and March; after the former period the wounds are apt to be injured by frost, and after the latter the sap is too far advanced; some is lost by bleeding, and the buds are developed too suddenly to admit of proper strength in the shoots. The cut should be made within three buds of the point whence the shoot issued, in a sloping direction, and the section on the under-side. (1865.) In cutting hoop-willows, the swell at the bottom of the shoot only should be left, that being furnished with abundance of buds for future growth. After being cut, the hoops are trimmed from any side shoots, and tied up in bundles of a hundred, of six scores each, which, in 1820, sold for from four shillings to five shillings a bundle. The willows are sorted into three sizes, and tied in bundles two feet in circumference, within a foot of the lower ends. When to be peeled, they are immediately after cutting on their thick ends in standing water, a few inches deep, and there they remain till the growth ascends freely, which is commonly by the end of the succeeding May. The apparatus for peeling is simply a two round rods of iron, nearly half an inch thick, sixteen inches long, and tapering a little upwards, welded together at one end which is sharpened, so as that it may be easily thrust down into the ground. When thus placed in a piece of firm ground, the peeler sits down opposite to it, and the small end is driven into the ground by the right hand; and the left hand is applied to the instrument, the prongs of which he presses together with the left hand, and with the right draws the willow towards him; by which operation the bark will at once be separated from the wood: the small end is then treated in the same manner, and the peeling is completed. Good willows peeled in the above manner, are fully six feet long; at from six inches, a foot and a half, at sixpence a bundle of four feet in circumference. After being peeled, they will keep in good condition for a long time, till a proper market be found.

6940. Copse-woods are generally cut over when the shoots of the stools have attained from three to five inches in diameter at their bases; some grown chiefly for hop-poles, and ware or stuff for crates, hampers, or wattled hurdles, are cut every year, and others, where small timber for fencing and other country purposes is wanted, are cut later. In some parts of Herefordshire, where the oak grows with great rapidity, the cut is made every three or four years; in some parts of Scotland, five years is the usual period; but in general the period is slower, the time varies from twenty to twenty-five or thirty years. "The bark is there considered as having arrived at its utmost perfection, and at its highest value, at the age of between twenty and thirty years: under that age, its virtues are weak; above it, the bark becomes coarse and loses its sap. Another important reason for cutting down oak copse-wood about the above period, is suggested in the Stirling-
Cuts the kinds of trees whose barks are not made use of, is winter and early in spring; but the oak and other trees which are peeled, are left till the middle of April or May. Birch and larch woods will peel nearly a month earlier than the oak. Should there be no frost, birch and larch may be peeled about the beginning of April; but the birch is commonly allowed to stand till July, and the larch is cut in the month of June. After the bark has been peeled, it is cut into strips, and an outer skin upon birch-bark which requires to be taken off, as it is of no use to the tanner, and renders that part which is of use more difficult to be ground, and the month of July is the only time at which the two barks can be separated with ease, as this time the sap is made to rise in the wood, and it is taken off without loss of time; and if the whole could be taken off before the leaf is completely developed, the bark would be better. After the sap has arisen to the leaf and new growth, the bark becomes more dry, and requires more beating to separate it from the wood. And when what is called the black sap is in the spring, the bark, and larch wood as well. It is always said that the bark begins to throw off for more especially young bark without much cork on it; this outer skin having less of the proper sap or juice, and being much drier when taken off, will weigh less, and consequently will not be so valuable. As good oak should be peeled by middle of June, every ton of bark taken off after the first of July will be deficient two cwt. per ton, compared with the same quantity taken off in May or early in June.

The termination of cutting is generally fixed for the fifteenth day of July, and after this date there should be no further operations. For the ground, it is imputed to the operation that in the last ten or fifteen, the whole of the wood and bark should be carried away, that the young growths may not be disturbed or injured, as at this time they will have made considerable progress; at any rate, there should neither be wood nor bark remaining within the new cut bag after the first of August; nor should either the trunk or branches be left for that period, as the sap turns into the leaves, and the bark forms what is termed a lammas growth, and the future prosperity and health of the coppice, in a great measure, depend on the first year's growth, as far as regards form and vigor of the shoots. (Forester's Guide, 61.) From the late season at which the trees to be barked are generally cut, they often receive considerable injury, both from the circumstance, and the manner in which the operation is performed. Munterah appears to us having furnished the best directions for executing the work in a safe manner. His instrument, with a swinging handle (fig. 140) through the cope, whose business is to trample down the long grass or foggage all round the root, and then, to make a circular incision into the bark so deep as to reach the wood, at about an inch above the surface of the earth; thus the bark when taken off, will injure no part of that which is below the circular incision.

The root of the tree being thus prepared, the cutters ought to proceed to the part of their work, not with an axe, however, as is most generally recommended, but with a saw, because, in cutting with an axe, the wood would be beveled in diameter, and the surface of the wood, instead of being cut as is, or most, the axe loosen the root to such a degree, that it not only loses the present year's growth, but often falls altogether to grow. Therefore if the diameter of the root be six inches, or upwards, it should always be cut with a cross-cut saw; entering the saw about half an inch above where the circular incision has been made to the bark, if it be ten or twelve, or more inches in diameter, the saw ought to be entered two inches above it.

There are two advantages to be derived from cutting with the saw; it has no tendency to loosen the root of the tree, but leaves it in such a condition as to be more easily and properly dressed; and also saves a portion of the wood that would otherwise be destroyed by the axe. On no pretense should oaks of six inches' diameter be cut with an axe, but always with a saw. Having cut through the tree with a saw, take a sharp adze, and round the edges of the stool or root, going close down to the surface of the earth, with the adze both bark and wood, sloping it up towards the centre of the tree, taking particular care always that the bark and wood both slope alike, as if they formed one solid body, being sure always that the bark be not detached from the root. An objection has been made to this mode of cutting with the saw, as taking up too much time; but I have found that two men can make a cross-cut saw incision in a few weeks, and will with a sharp adze and a fine double edge, cut a man as fast as they will with a broad axe. (Forester's Guide, 62.)

The disbarked timber is prepared for sale by being sorted into straight poles of the largest size, stakes and other pieces fit for palings, faggots, fuel, &c. The unbanked wood is similarly sorted, and afforded, when in season, for bundles of clean brush, and lumps, for kindling fires, poles for hedges, &c, poles for hoes, larger poles for fences, rails, paling-stakes, stakes and shods for hurdles, besom-stuff, spray for distillation, and a variety of other objects according to the local demand, or the opportunity of supplying a distant market by land-carriage. The brush or spray of non-resinous trees is called in some places ton-wood, and is used for distilling the prorogulose acid used in bleach-fields and calico-print-works. "When wood of this description is sent to Glasgow, where there are extensive works for the purpose of distilling it, it sells readily at from £2. 6s. to £10. per ton; but when there are large quantities of it in the market while it is being carried to market, there is too much competition among boilers can be erected at no great expense, and in this case the liquid is easily carried in casks to which it is consumed, at less expense than the rough timber could be; of course it will pay much better. Small wood of this description is also used for charcoal; but in distilling it, there is part of it made into charcoal, and lime, &c, for the furnishing of stoves; so that it is not a bad article, for there is any great quantity disposed of, to erect boilers and distil it; unless where the local situation of the wood will admit of its being shipped at a small expense, and carried to where the works mentioned are; but a proportion of wood of this description is extracted for the making of pitch, tar, and chestnut, and birch, are the best." (Forester's Guide, 153.) When the oak grows slow, as in the highlands, the but-ends of the poles are used for spokes for chaise-wheels. "Long spokes are from thirty to thirty-two inches by three inches and a half broad, and one inch and a half thick, and the short ones for the same purpose, from twenty to twenty-four inches long, and the same sizes otherwise. Cart-
Preparating which but these because and these can the of
square these take separate the long ing other, branches, those are the thickness of a paling-stake, and have a forked end on each about six inches long, the other end sharpened to go into the ground; two of these horses are placed in a triangular form against one another, one end of the piece to be peeled being raised on the horses, the two barkers standing opposite to each other, and entering the peeling-iron into the incision made by the mallet, and pressing the iron downwards between the bark and the timber. In this way it will be found very easy to take the bark off in one whole piece round the tree; and, if possible, let these pieces be as long as the incisions made in the bark. In some cases, where there is not much sap, the bark may require a little beating with the square end of the mallet, to cause it to separate easily from the wood; but the less beating with the mallet the better, as it has a tendency to blacken the bark in the inside, or fleshy part of it, so that when the tanner sees it, he supposes it to be damaged, and undervalues it. The branches of the tree being previously all lopped off with the axe, the persons, in number according to the extent of the work, with the bill smooth all the branches, cutting them in lengths of from two feet six inches to three feet, down as small as one inch in circumference. The barkers, principally women, are each provided with a smooth hard stone of about six or eight pounds weight, beside which they sit down, and having collected a quantity of saplings, branches, or twigs, they hold it on the stone with one hand, and with the mallet in the other, they beat the piece till the bark be split from the wood, from the one end to the other, and taking it all the length of the piece, if possible, then lay it regularly aside, till a bundle of considerable size is formed.

6950. Drying the bark. "The point most particularly to be observed in this art is, putting the bark up to dry, which is done by putting them on the ground, or ranges or ranges. These are erected by tacking the pieces of the loppers, called horses, the one three feet long, the other two feet six inches, and driving each about four inches into the ground, opposite one another, about two feet asunder in the breadth, and as much betwixt them, lengthways, as will admit long small pieces of wood to be put upon them. The mallet must be laid on every day's peeling, and it ought to be erected in as dry and elevated a spot as can be found in the margin of the wood or better outside of it. The bark being carried and laid on this loft, with the thick ends of it all laid to the high side of the range, and the small bark laid with the thickness of it to the side; and the bark taken off the large bark, and wood laid in regularity on the top, which serves for a covering, and the lots or ranges having a declivity of about six inches, the rain will run off them readily, and if properly put up in this manner, they will take out a great deal of rain. After it has lain in this state for three days, if the weather is good and dry, it ought to be all turned over, and the small bark spread out, so as not to allow it to sit together, which, if much pressed, is apt to do, and if it does so with the natural sap in it, it has a chance of moulding, which is extremely hurtful to the bark, and both lessens it in weight and in value. After the bark has stood on the ranges about eight or ten days, if the weather be good, it may either be put into a house or a shed, or if intended to be put up into a stack, it may now be done." A stack of bark ought never to exceed eight feet in width, and twelve or fifteen feet in height, raised in the middle like a haystack. If it is to stand any length of time in the stack, it ought to be thatched, and in that state must remain in the same to be taken out. The greater part of the cork of the bark, because the color of it is generally looked to as a principal criterion of its value, and the merchant or tanner judges of its value chiefly by its color. Before being put into the stack, the natural sap ought to be dried out of it, in order to preserve it from fermenting, because if a ferment occurs, its influence passes through and spoils the whole. The same mode of treatment will do for all kinds of bark as well as the oak; but the birch has an outer or shrey skin upon it, that is of no use, and rejected by the tanner, and, as already observed, must be peeled off. "When the bark is ready for the tanner, it has to undergo the work of chopping, which is done by driving in two or more stakes into the ground, with a fork on the upper end of each, leaving them about two feet six inches from the ground, and laying a small piece of wood across between the two, where a number of people stand, and then the fork being laid down, a mallet put into the forks, which is carried in the hand from the cross-tree, and then, with a sharp whittle or bill in the other hand, they cut it into small pieces, about three inches in length; when this is done, it is trampled into bags, which hold about two hundred weight each, and in these bags it is weighed when sold by the ton, in tons, hundredweights, quarters, and pounds, and in the above manner delivered to the merchant or tanner." (Forester's Guide, 193.)

6952. Pollard-trees, which may be considered in most cases as injurious deformities, are lopped at stated periods like copses-woods, and the top, whether to be barked or otherwise, is to be treated in all respects like that of rope.

6953. The period at which trees are felled, for the sake of their timber, is determined by various causes. By maturity of growth, or where the annual increase is so trifling as
PRACTICE and the decay.

970. In trees, as in the human species, there are three stages, youth, manhood, and old age. In the period of youth, the growth is rapid; in manhood, that growth is matured; and in old age, it begins to decay. (Treat. on Countr. Reg. i. 277.)

954. The most profitable season for felling timber is at what may thus be termed the beginning of manhood. After that time, though the tree may appear sound and healthy, its annual increase is so little, that it would be more profitable to fell it and replace it, than to leave it at the period, must vary in different soils and situations; but the period itself may easily be ascertained — by the annual shoots — the state of the bark — and by taking the circumference of the tree at the same place for two or three successive seasons, and comparing the difference. In the view of profiting from timber produce, it is of great consequence to cut down plantations at maturity. Many trees will stand half, others a whole century, after they are full-grown, appear quite healthy, and, at the same time, make little or no increase of timber. But there are particular cases, arising from the nature and state of the markets, where it may even be more profitable to cut timber before it is arrived at a full growth. (Treat. on Countr. Reg. ii. 277.)

955. Preparations for felling. It has been strongly recommended to disband trees a year or more before they are taken down in consequence of the result of certain experiments commenced by Buffon in the year 1757. In May of that year, he disband three oak-trees, forty feet in height, forty feet in girth, and, on cutting them down, the outer wood was found hard and dry, and the barks and trunk were found to be much loose and easy to be separated from the internal wood moist and softer. After trying its strength, &c. he concludes, that "timber which has been disband and dried while standing, will weigh heavier, and prove stronger than timber cut in its bark." (Encyc. Brit. Suppl. art. Timb. &c. Comp. trans. in Cont. by Aubin, Bot. Paris.) As late as 1760, most authors, and most editors of the Encyclopaedia, recommend the practice, which is followed in some places on the continent, and in this country with the oak and larch; but not, as far as well known, with any other tree. Montateh finds it by far the most efficient way of seasoning larch-timber. He barked some trees in spring, and others stood in the peeled state for two years. After various and extensive trials, he decided, that the larch treated in this way at thirty years of age will be found equally durable with a tree cut down at the age of fifty years, and treated in the ordinary way." (Forester's Guide, 123.)

956. As the dry rot (Merulius destructus, Sow.) is found to arise in a great measure from want of seasoning, or at least to proceed with the greatest rapidity in timber not well seasoned, this practice seems to deserve adoption in that point of view. (Encyc. Brit. Suppl. art. Dry Rot.) In some parts of the north of Europe, the trees are uprooted, or cut down for one or two feet in height from the ground a year or more previous to staggering or felling them, on which they are to be felled. We saw this done in Poland and Lithuania; but though we made diligent enquiry in Sweden, we could not learn distinctly the extent to which it was practised in that country and Norway. It is occasionally practised in both for the ostensible purpose of hardening the soft wood; but also accomplished by decay induced for the purpose of extracting tar; a practice obviously injurious to the timber, and therefore generally in these countries kept out of view. When trees stand close together, a very obvious preparation to felling is lightening the tops of such branches as would do injury in falling to the trees that are to be cut, or to other adjoining objects.

957. The season of felling is commonly winter, for timber not to be disband; but some for the resinous tribe recommend summer as the season in which it is generally felled in the north of Europe and in the Alps. But the summer season is there adopted from necessity, as in winter the woods are so filled up with snow that felling is hardly practicable. As the timber of these countries is generally squared for the market; the soft wood is chiefly removed, so that the season of felling does not seem as to them to be of much consequence. Besides, the timber is never so full of sap in summer as it is in spring and autumn, and therefore, next to mid-winter, midsummer may be the next best time for felling all kinds of timber-trees. Where the trees are disband at the base a year or more before felling, the soft wood will be partially hardened; but this practice is by no means general in the north.

958. Knowles, in a recent work on preserving the British navy, the dry rot, &c. after collecting the opinions of all the ancient and modern authors who have written on felling timber, concludes, that the common notion that trees felled in winter contain less of sap or of the vegetable juices than those cut down at any other season of the year, is not true; and that the method of barking standing trees in spring, and not felling them till the following winter, has nothing in it. With regard to the preservation of all the different modes that have been adopted for seasoning timber, he concludes, that the best mode of seasoning is to "keep it in air, neither very dry nor very moist; and to protect it from the sun and rain by a roof raised sufficiently high over it so as to prevent by this and other means, a rapid rate of decay." (Inquiry into the Means of preserving the British Navy from Dry Rot, &c. by Knowles, &c. to the Com. of Surveyors, chap. iii.)

959. The operation of felling is performed either by digging an excavation round the stem, and cutting the roots at two or three feet distant from it, or by cutting over the stem at the surface. By the former mode the root is obtained for use, and the ground more effectually cleared and prepared for the roots of other adjoining trees, or whatever crop is to follow. Where the tree is intended to be stol, which can very seldom be advisable in the case of cutting full-grown timber, or there is some nicety in taking it down so as not to injure other trees or adjoining objects, it is cut or sawn over, and the root, if to be removed, dug out afterwards. "In cutting large trees, in order to make the tree fall the way required, enter the cross-cut saw on that side of the tree it is intended to fall, and cut it about a third part through; then enter the saw at the other side, and when it is cut so far as to admit a wedge, place the wedge exactly opposite the way you
want the tree to fall, and keep driving it slowly till the tree is nearly cut through.

(Montcath.)

6960. Disbranching. The tree being felled, is next directed of its branches, which are sorted into fence-wood, fuel, top-wood, &c., according to the kind of tree; and the trunk is generally preserved as entire as possible for the purchaser. Sometimes it is cut in two, and the root-cut, or but-end, being the most valuable, sold for one class of purposes at a higher price, and the top-cuts for others somewhat lower. Sometimes timber is purchased by private contract by the foot or load in a growing state, or after being cut down; in other cases portions are made annually, and the produce exposed for sale by auction. It is measured by the cubic foot, fifty of which are a load; and the calculated tables and Measure's Guide generally resorted to, are those of Hoppus.

6961. The roots of trees are the last product we shall mention. These should, in almost every case, be effectually eradicated; to aid in which, in the case of very large roots, splitting by wedges, reftting by gunpowder (1941.), tearing up by the hydrostatic press (fig. 211.), or by a common lever and triangle (fig. 666.), may be resorted to. Some compact ash or oak roots are occasion-
ally in demand by smiths, leather-cutters, and others; but in general roots should be reduced to pieces not exceeding three feet long, and six inches in diameter, and put up in stacks not less than three feet every way, but commonly containing two cubic yards. These, when dry, are sold for fuel, or reduced to charcoal on the spot. In eradicating and stacking up coppice-woods, it is common to allow a certain sum per sack, something for every acre of ground cleared; and if there are no trees to bark, the allowances are also made for the poles, faggots, &c. so that no part of the operation is performed by day-
work.

6962. The usual method of charring wood is as follows:

6963. The wood being collected near the place intended for the operation, and cut into billets, generally about three feet in length, the pits or stacks are usually formed in this manner: A spot, adapted to the purpose, of from about fifteen or twenty feet in diameter, of a conical form, is selected, and after being properly levelled, a large billet of wood split across at one end, and pointed at the other, is fixed in the centre of the area, with its pointed extremity in the earth, and two pieces of wood, inserted through the clefts of the other end, forming four right angles; against these cross-pieces, four other billets of wood are placed, one end on the ground, and the other leaning against the angles. A number of large and straight billets are afterwards laid on the ground, to form a floor, each being, as it were, the radius of the circular area; on this floor, a proper quantity of brush or small wood is strewn, to fill up the interstices, when the floor will be completed in order to keep the billets in the same position in which they were first arranged, pegs or stumps are driven into the ground, in the circumference of the circle, about a foot distant from one another; upon this floor a stage is built, with billets set upon one end, somewhat inclining towards the central billet, and on the tops of these another floor is laid, in a horizontal direction, but of smaller billets, and the whole is intended, when finished, to form a cone. The whole is then coated over with turf, and the surface generally plastered with a mixture of earth and charcoal-dust.

6964. Precious to the operation of setting fire to the pile, the central billet in the upper stage is drawn out, and pieces of dry combustible wood substituted in its place, to which the fire is applied. Great attention is necessary during the process. The proper management of the fire, and in immediately covering up the apertures through which the flame obtrudes itself, until the operation be concluded, which is generally effected in the space of two or three days according to circumstances. When the charcoal is thought to be burnt, which is presently known from the appearance of the smoke, and the flames no longer issuing with impetuosity through the vents; all the apertures are to be closed up very carefully, with a mixture of earth and charcoal-dust, which, by excluding all access of the external air, prevents the coal from being any further consumed, and the fire goes out of itself. In this condition it is suffered to remain, till the whole is sufficiently cooled; when the cover is removed, and the charcoal is taken away. If the whole process is skilfully managed, the coals will exactly retain the figure of the pieces of wood: some are said to have been so dexterous, as to char an arrow, without altering even the figure of the feather. (Kinngle Brit. Art. Charcoal.)

6965. The method of charring wood, for the making of gunpowder, according to an improved system, adopted not many years ago, is however a much more costly operation, though the expense attending it is amply compensated by the superior excellence of the article when manufactured. It is done in iron cylinders, and in so complete a manner, that every particle of the wood is charred. The oily or tarry matter is also preserved, and may, so far as the quantity goes, be made use of instead of foreign tar or pitch. This mode of charring wood for making gunpowder, is carried to the greatest perfection, near Pevensey in Sussex, and there is a manufacture of a similar nature near Chester. (Gen. Rep. for Scotland, vol. ii. p. 332.)

6966. The valuation of trees forms a distinct profession, and can only be acquired after much experience; like other valuations of property, it depends on a great variety of consider-
ations, some of a general, but the greater part of a local nature. All we shall here attempt, is to give a few general ideas which may be of use to the private cultivator or forester.

6967. In valuing any plantation, the first thing is to know its contents in acres; if this cannot be done, the number of plants must be counted. If a young plantation, the trees of which are unfit for present use as timber, is to be valued, then its value at any distant period, not exceeding twenty or twenty-five years, must be estimated; and whatever sum that estimate amounts to, the present value of that sum will give an idea of the value of the plantation, allowing liberally for accidents to the trees and other unforeseen circum-
stances. Thus, suppose a plantation of oaks, intended as copse, or actually established as
such, to have grown four years, its present value would be next to nothing; but if arrived at its twentieth year, it would fetch fifty pounds per acre. Then the question is, required the present value of fifty pounds, due sixteen years hence, the market price of money being five per cent. and this, according to any of the modern annuity tables (say Bailey's, 4to. 1808. tab. iv.) is 22f. 18s. This principle is applicable to all kinds of valuing by anticipation; and there is no other mode of valuing applicable to young plantations. The benefits derived from the trees in the way of shelter and ornament, are to be estimated in valuing the territory, and are foreign to the present purpose, which has for its object tree-produce only.

6998. In valuing salvable trees of any kind, their number per acre, or their total number by enumeration being ascertained, and the kinds and sizes classed, then each class is to be estimated according to its worth and utility. In timber, bark and charcoal are valuable. In a coppice-wood which cannot readily be measured, the readiest method of counting the stools is, to cause two men to take a line, say about a hundred feet long, or more, and passing the line round as many of the stools as it will enclose, the one man standing still while the other moves round a new number of stools, and count always the stools betwixt the two lines, causing the one man to move the one time with the line, whilst the other man stands still, and so on alternately. The valuator at the same time taking care to average every twenty stools as they go on, before losing sight of the counted stools. This way, too, is a very speedy and sure method of counting the number of trees in any plantation. Or, the stools of a coppice-wood may be counted and averaged by two men going parallel to each other, and the person valuing going betwixt them; the two men putting up marks with moss, or pieces of white paper, on a branch of the stools; the one man going always back by the last marked stools, and the valuator always counting and averaging the stools betwixt the newly-laid and the late-laid lines, by which averaging the stools always as the men go on, taking only twenty, or even ten stools at a time. To those who have been in the practice of doing this frequently, it will be found very easy, and will be done very speedily, and with a very considerable degree of accuracy. The proper method of learning to do this correctly is, when a person cuts an oak wood for the first time (or, even were the work new-come), he will find it, in order to make himself perfectly acquainted with ascertaining the average quantity of bark that a stool, or even a stem of a stool will produce, go before the peelers, and select a stool or stem: after having examined it narrowly, he supposes it to produce a certain quantity of bark, and marks this down in his memorandum-book. He then causes a person to peel it by itself, at every other stem, and carefully weigh the weight he supposed it to produce, and he will at once see how near his calculation comes to the truth. A stem of oak from a natural stool, suppose it to measure in girth two inches, by seven feet long, will contain two solid inches and one third of an inch, according to the measurement of Hoppus. This stem or shoot will produce two pounds two ounces of bark. Again, a stem or shoot of natural oak, measuring four inches in girth, by nine feet in length, will be found to contain one solid foot of wood, and will produce thirteen pounds and a half of bark.

(FORESTER'S GUIDE, 170.)

Hence growing trees are valued, an allowance is made from their cubic contents for the bark. The rule given by Montech is, when the girth or circumference is any thing from twelve inches up to twenty-four inches, then deduct two inches; from twenty-four to thirty-six, three inches; from thirty-six to forty-eight, four inches; from forty-eight to seventy-two, five inches; and above seventy-two, six inches. This is, the deductions he finds by experience, be found to answer in almost all trees; unless in such as are very old, and have rough and corky barks or barks covered with moss, when an extra allowance is to be made. (FORESTER'S GUIDE, 180.) Many persons, the same author observes, in valuing measurable oak trees process by another method. The stem of timber will produce a stone (sixteen pounds) of bark. This, he says, is not always correct; and he states the following facts from his own experience, with a view to assist beginners in ascertaining the quantity of bark from various trees. An oak-tree, about forty years old, measured down to four inches and a half side of the square, and weighing only the bark peeled off, is measurable without including any of the bark of the spray, i.e., every foot of measured timber will produce from nine to eleven pounds of bark. An oak-tree, of eighty years old, weighing only the bark peeled off the measurable timber, as above, every foot will produce from ten to thirteen pounds of bark. Every foot of large birch-timber, peeled as above, will produce fourteen pounds of bark. Every foot of larch-timber, peeled as above, will produce eleven pounds and a half of bark. Every foot of the willow, unless a very old tree, will produce from nine to eleven pounds. Every foot of larch fir, not exceeding thirty years old, will produce from seven to nine pounds of bark. The timber of trees, particularly the oak, is peeled out, every branch and shoot, down as small as an inch in circumference. (FORESTER'S GUIDE.) Hence the prices of trees to the different parts of the country, will vary as the demand and supply; and is easily ascertained from the timber-merchants at the different sea-ports; as that of bark, charcoal, and firewood from the tanners and coal-merchants.

6970. To facilitate the measuring of standing timber, Montech has invented a very ingenious machine. (fig. 667.) It consists of a wheel, or perambulator, about eight inches in diameter, with a bell (a) on the end of its axle; at the end of every foot gone over by the serrated circumference of the perambulator, this bell is struck by means of a spring (b); the sound of this bell will be heard from the top of the highest tree. A forked handle (c) works on the top of the main axle on each side of the wheel; one of a set of connecting rods (e, h) goes into it, and is fixed with a screws making a swivel joint, and by screwing the nut firm, the wheel can be set to any position, and it will work equally well any way. A small hand (d), in the circle of the triangular spring, points to the inches or quarters of an inch on the wheel, and tells what excess the inch after a lesser spring (e), which strikes at every inch, has struck the bell. The circumference of the wheel (f) measures two feet. The rods for working the measuring machine are each three feet long, and one inch in diameter, with connecting screws of brass on each end of them; so that as many as are
required for any length or height, can be easily screwed into each other. The other small rods for taking the length of the tree, as also of its branches, are only five eighths of an inch in diameter: each rod is three feet long, and goes together with connecting screws of brass. The rods are painted black, and divided into feet and inches, with white letters; so that by connecting any number of the rods together that may be required, and by applying them to the tree or branches (\( \ell \)), you can take the exact length in a speedy, accurate, and simple manner. (Forester's Guide, 207.)

6971. The value of the invention turns on the use of the wheel, in taking the girth of the tree. Thus "after having taken the length of the tree in feet and inches, which length may be taken by the rods as already described, the girth is most generally taken at half the length, which girth we are enabled to take with the measuring wheel: this is easily done, by putting up the wheel, with as many of the connecting rods together as will put it up to the height required; then, suppose there are no branches; in the way, and having before made a mark on the bark of the tree with the small rods, the uppermost one having a small marking-iron in its end for that purpose; this mark is made where the girth is to be taken, and from where you are to take your departure with the wheel, which being done, press the wheel round the tree, following it, and keeping it as level as possible, which will in great measure do of itself, by its having teeth like a saw in the hem of the wheel, unless carelessly attended to. As the wheel goes round the tree, be sure to count the number of times the bell strikes, which it does at every foot; and when you see you have not another twelve inches or one foot more to run, to arrive at the place where you took your departure from, count the number of inches that it strikes over and above the last foot, and thus you will at once have the feet and inches that the tree is in circumference; of which take the fourth, and this gives you the side of the square: but when there are branches in the way of getting round the tree, you must have a spare handle for the machine (c, b), about two feet, or two feet six inches in length, and by altering the swivel-joint at the top of the first rod to any position required, the person working the wheel by the rods can stand in the same place, and put the wheel, say half way round the tree, if it is very large, and by turning the swivel-joint, and reversing the wheel, at the same time sending it round the other side of the tree till it meet where it left off, and by counting the feet and inches as above, and adding the two together, you will at once have the extreme girth of the tree. When branches are to measure, or when branches are in the way of getting round the tree with the rods, the person with the small rods stands on the opposite side of the tree, and directs the person when to stop with the wheel. Thus, by a little practice in working the wheel, and paying attention to count the feet and inches as they strike, two men will measure growing or standing trees equally as accurately and expeditiously as if the trees were lying on the ground. In taking the girth with a line, you have first to put, it round the tree, then you double it, and apply it to a foot-rule; you then take the half for the side of the square, whereas this machine gives you the exact feet and inches from the top of the highest tree, without the help of any other rule" (Forester's Guide, 208.) Neither this machine, nor a mechanical dendrometer, invented about twenty years ago, though both of considerable merit, appear to us to be warranted for general use as the Niseometer of Broad. (fig. 154.)

6973. The books of accounts for trees and plantations have already been mentioned. (2340.) Some have proposed measuring the whole of, or at least all the detached and hedge-row trees on an estate periodically; numbering each tree, and keeping a corresponding register, by which the proprietor, when at a distance, might give directions for cutting down particular trees, &c.; but this appears rather too much in the mercantile style for the dignified enjoyment of landed property, and does not promise any very great advantages.

CHAP. VII.

Of the Formation of a Nursery-Garden for the Propagation and Rearing of Trees and Shrubs.

6973. Nurseries for rearing trees are commonly left to commercial gardeners, as the plantations of few private landowners are so extensive, or continued through a sufficient number of years to render it worth their while to originate and nurse up their own tree and hedge plants. Exceptions, however, occur in the case of remote situations, and where there are tracts so extensive as to require many years in planting. Besides, as Sang observes, "some are of opinion, that trees, in order to their being rendered sufficiently hardy, should be reared on the soil and situation where they are ultimately to be planted; and if the design be extensive, and such as may require many years for its completion; a conveniently situated nursery is, in that case, highly desirable, not only as saving the carriage of plants, and facilitating the business of transplanting, but as increasing the chance of success, on account of the plants remaining a much shorter time out of the ground than if brought from a distance. If the situation, however, ultimately destined for the trees be cold, high, and bleak, and the soil of course various, some good, and much of it bad, or of an indifferent quality, there it would by no means be advisable to attempt the establishment of a nursery, and especially a nursery to raise plants from seeds. The chief properties of nursery plants intended for transplanting, consist in their strength and clearness of stem, and in their roots having a multiplicity of healthy fibres; and in order to obtain plants possessing these qualities, it is necessary to sow, and plant out to nurse, if not in rich, at least in mellow earth, and in a moderately sheltered situation." (Plant. Kal. 20.) The following directions by Sang as to the soil, shelter, aspect, and fencing of a nursery-garden are equally applicable to such as are intended for private or commercial purposes: —

6974. In order to have a complete nursery, it should contain soils of various qualities, and not less than eighteen inches or two feet deep; the generality of it should be light friable earth; a part of it should be
of a clayey nature; and another part should be moosy. Each of these will be found peculiarly useful in the raising of the different kinds of young plants. The whole should be well drained, and trampled, and cropped with vegetables for one or even two years previously to sowing tree-seeds. For transplanting, it may be necessary to be over-heated, but this is likely to happen only in the case of its being very small; for, if it extend to several acres, unless it be surrounded by very tall trees, the area will be considerably exposed. No part should be either too much exposed, or too much sheltered. Any aspect from east to west, following the course of the sun, will answer. Ground of an unequal surface is most. But one or two shallow hollows and several slight rises in the ground will be beneficial. Other soils than those already described may also be used for nursery purposes, but, in general, rise from a level to a pretty smart acclivity; yet no part of it should be too steep, because it is in that case very troublesome to labor. The nursery-ground may be sufficiently fenced by a stone wall, or even a hedge six feet high; and if it be of small size, an acclt or a hedge-row, it will require no other shelter but provided for, i.e., raised or protected, for the purpose of water and shelter; and, to this end, the young trees of their fruit, and to cause them to be bare and stunted, by the nature of being planted in the forest. It would be very convenient to have a roll of water passing through the ground, or to have a small pond, fed by a spring or ditch, for the purpose of watering. [Pl. Nat. Kal. 52.]

675. In preparing the soil for the culture of trees it will be advisable to trench it to its full depth, and necessary, the same author continues, "to give it a good dressing of lime or marl and dung in compost. Rank manure, such as stable-litter, should not be applied to nursery-ground, as the same of compounding with nursery articles and, if it be necessary to enrich it, this should be done by a manured crop of onions, turnips, lettuces, or the like. Potatoes should never go before a crop of seedlings, even of the smaller sorts, as as, ok, or chestnuts; because potatoes never can be taken clean out of the ground; and it being indispensable to pull up those which rise among the tree-seedlings, two or three, to rot off their coverings, it will make the potatoes, turnips, lettuces, cabbages, or the like, should rather precede the crop of seedlings. The best kind of management in this particular case, is to interchange the crops of timber-trees and esculents occasionally; perhaps, with respect to most sorts of seedling-plants, alternately observing to sow all small seeds, in particular, if not in a rich, at least in a fine tilt." [Pl. Nat. Kal. 24.

676. For a private nursery, he continues, "no place, certainly, can be more eligible than a field, which may also be occupied as a kitchen-garden. If, for instance, three acres were required for the purposes of nursery, a field of five or six acres would also require for establishing a kitchen-garden, or for green crops, for cattle-feeding, it would be proper to enclose five or six acres, less or more, according to circumstances; by which means two important objects might be obtained, viz. land of a good quality, and fine tilt, for the raising of seedlings; and an opportunity of effectually changing crops at pleasure. Certain and improved measure for preserving young seedlings, which were very seldom found a good crop of trees following one of carrots; while we have found peas, beans, and especially lettuces, easy and enriching crops, well adapted as predecessors for succeeding crops of nursery articles."

677. In so far as respects public nurseries, "we have long remarked, that the choice, or as much as possible, of the nursery-ground, is what determines the best nurseries and young articles, for sale; provided that the soil not be anything more than of a middling quality. This fact, if one were wanting, is a sufficient proof of the utility of occupying the ground as above advised, in the double character of a kitchen-garden and nursery!"

678. As a cold climate, or bleak situation, "with a poor barren soil, we would by no means advise the raising of seedlings, either in public or private nurseries. It will be found a cheaper, as well as a more satisfactory method, to purchase seedlings, transplant them, and nurse them till fit for final planting; and, even, in this case, a piece of the best, and most sheltered land in the situation, will be necessary for the purpose." [Pl. Nat. Kal. 26.]

679. A rolling-ground will be required for the preparation of certain seeds, by mixing them with sand, ashes, or soil, and leaving them there for different periods, from six months to two years, to rot off their interior coverings. On a small scale, a portion of the compost-ground of the kitchen-garden may be used for this purpose. If the scale is large, an area of a few square poles should be set apart for bedding in plants taken up for replanting, or what is called laying in by the heels, or shoughing: this is generally called the bedding-ground or (in Scotland) the shoughing-ground. If the situation of the nursery be next to the kitchen-garden, and the latter have the proper office-buildings (1701), no other erection will be required for the nursery than a working-shed for ordinary purposes, occasional shelter, and protection to newly taken up plants; and for packing or tying them up properly before sending them out, according to their final situation, &c. From this shed they may be conveyed to the more tender seedlings and seedlings; and, on a large scale, a seed-loft and its appendages, as well as an office for writing, &c. may be erected from those belonging to the kitchen-garden.

680. Stacking with plants. The ground being arranged, and prepared by one or more vegetable crops, the next things to stock it with stooks, or stock plants, to propagate from by layers, and to procure stocks for grafting or budding, but especially in a private forest-tree nursery with tree-seeds. In the tables of ornamental trees and shrubs (5340. to 6571.), given in the preceding book, and in the general index at the end of the work will be found the particular mode of propagation and the requisite soil for each tree and shrub: by inspecting these sources it will be seen what plants must be procured for stocks. If the object is merely culture, few, excepting some of lime, poplars, and planes, will be required; but, if tender trees and shrubs are to be reared, by the number of the species, and the care to be taken in the sheltering house, it must be more hardy in the open compartments: the tree kinds may be placed from six to eight feet every way, and the more delicate shrubs from three to six feet apart in suitable soils. Stocks for grafting, whether for fruit or barren trees, are to be planted in nursery rows, according to their kinds; those for iarcing round the parent plant (5007.) or in pots.

Chap. VIII.

Of the Culture and Management of a Nursery for Trees and Shrubs.

682. The principal objects of culture in a private tree-nursery are the hardy trees and shrubs of the country, which produce seeds; and the great object of the private nursery-gardener must be to collect or procure these seeds, prepare them for sowing, sow them in their proper seasons, and transplant and nurse them till fit for final planting. We shall arrange the principal trees and shrubs which ripen their seeds in this country; as cones, nuts, berried stones, berries with small seeds, leguminous seeds, and small soft seeds.
Before treating of the gathering, storing, separating the seeds, sowing, and nursery culture, of each of these general divisions, it is essential to remark, that in collecting every kind of tree-seed, preference should be given to that produced by trees the largest and most perfect of their kind, and to the fullest and best-ripened seeds on these trees. The reasons have been too frequently given in this work to require repetition.

**SECTION I. Coniferous Trees and Shrubs, their Seeds, Sowing, and Rearing.**

6983. The principal coniferous trees and shrubs are as follow: —

<table>
<thead>
<tr>
<th>Coniferous Trees</th>
<th>Principal Coniferous Shrub</th>
</tr>
</thead>
<tbody>
<tr>
<td>Juniperus virginiana</td>
<td>Pinus strobus, October</td>
</tr>
<tr>
<td>Cupressus thumberiana, Jarium</td>
<td>pinuster, December</td>
</tr>
<tr>
<td>Cupressus sempervirens, January</td>
<td>cedrus, March.</td>
</tr>
<tr>
<td>Pinus sylvestris, November</td>
<td>Thuya occidentalis, November</td>
</tr>
<tr>
<td>- lirax, December</td>
<td>- montana, November</td>
</tr>
<tr>
<td>- cinerasia, November</td>
<td>- pines, December</td>
</tr>
</tbody>
</table>

6984. Cones may be gathered any time between the ripening season and the following April; but the sooner they are gathered the better, as they supply work for the regular hands of the establishment in bad weather during the winter months; or admit of giving industrious money-making persons work by the job in the winter evenings. The general mode of separating the seeds is by kiln-drying, in the same way as in drying malt, but applying more gentle heat.

6854. The cone-kiln is constructed after the manner of a common malt-kiln; the bearers should be about two feet distant from the front and two inches apart. A wire cloth is spread over them from side to side of the kiln, and the cones are laid on it to the thickness of twelve or fourteen inches. A gentle fire is then applied, and regularly kept up till the cones are opened. During the time of drying, the cones must be frequently turned upon the seat. When the cones are opened, they are removed to the seed-heap, and sifted till all the seeds which are loose fall out, and be taken from among the cones. The cones are afterwards to be thrashed severely with flails, or passed through a hand-threshing machine, and sifted as before, and so on, till the seeds are taken out as completely as possible. It is, however, a safer method of separating them in the kiln. This operation is performed by a small flat triangular spatula, sharpened at the point and cutting-angles, and helved like a shoemaker's awl. The cone is held by the fore-finger and thumb of the one hand, upon a flat piece of wood, while, with the other, by the splitter, it is laid open from the great end, and after each half split up the middle, while in parts the cone is cut into four divisions. This is by far the best and least destructive to the seeds of any method we know; because the cones so split, when exposed to the heat, are suddenly opened, and readily discharge the seeds; which, consequently, are less injured by the fire-heat. Besides the above method of splitting, there are others. Some people use a cone-mill, which has large apparatus in a conical cylinder, and others fixed in a corresponding roller. The mill is wrought by turning the roller by a handle resembling that of common fanners. The cones are let into the mill by a hopper. This instrument is very difficult to work, and bruises the seeds very much, and does not separate the seeds from the scales. We have several times made use of the common improved bark-mill, for separating the seeds from larch fir cones; but the cones are so compressed and bruised, that the seeds suffer exceedingly; and we would by no means advise it: indeed, among all the methods which we have known adopted, to produce the laborious and hazardous work of extracting the seeds of the larch, the plan of splitting them singly is much the best and safest for the seeds, and ought to be adopted by every one who has occasion to use only small quantities of seed. None of the other kinds of cones require so much labor as the larch, excepting, perhaps, those of the cedar of Lebanon, and black American spruce. Cones, which have given out all their seeds, are generally, and very properly, used as fuel for drying other cones. This sort of fuel requires the attention of a very steady feeder; indeed, the most careful and attentive are apt to set the full or drying cones on fire, from the resinous nature, and tendency to flame, of the empty cones used as fuel. Such kilns should, therefore, be erected in situations far removed from a dangerous neighborhood.

6856. The cones of Scots pine, the larch and the spruce. "are the principal kinds which are opened by kiln-heat. The cones of the silver fir, the balm of Gilead fir, and the Weymouth pine, give out their seeds with very little trouble: indeed, if they be not gathered soon in autumn, and kept from severe drought, they will fall to pieces of their own accord. Seeds of the white American spruce are only procured from warm situations, and from America, and are generally sold in a clean state, or separated from the cones. Cones of the black and red spruces are brought from America, and are in the state of cones. These should be split, and exposed in a sieve tilted before a gentle fire, with a sheet of paper below the sieve to receive the seeds as they fall out. The seeds should be removed every quarter of an hour; because they are small, and are very easily injured by the heat."

6987. The cones of cedar of Lebanon "should be kept for one year at least, after they are taken from the tree, before the seed be attempted to be taken out. This is necessary, on account of the soft nature of the seeds, and the great quantity of resinous matter which the cones contain when growing, and which is discharged by the keeping. They should be laid open by a sharp cone, and piece of iron through the heart of them. This work, as well as the taking out of the seeds is greatly facilitated, by steeping the cones in water for a day or two, previous to splitting them. The coats of the leaves should be opened with the hand, and the seeds carefully taken out. The cones of the cedar of Lebanon should be purchased with safety for seed, although it be several years since they were taken from the tree." (Plant. Kat. 392.)

6988. Sowing. April is the best season for all the species; the soil should be in excellent condition, well mollowed by the preceding winter's frost and snow, carefully dug and raked as fine as possible. All the sorts are sown in beds, excepting the cedar of Lebanon and some pines; and the manner of sowing is by cufing or bedding in, already described. (1857.)

6989. The soil for the Scotch pine, before being dug over in February, should be thickly coated with rotted cow-dung: the seed should be sown so as to rise at the distance of a quarter of an inch from one another; and the covering should be half an inch thick. The best preparation for larch-seeds is a previous crop of two-years' seedling Scotch pines, and next, a similar crop of the larch. The soil should be ploughed and prepared for sowing in March and April; and after this, the seed should be sown, and the covering removed, draw a light roller along the bed, to press the seeds firmly into the earth; then cover a quarter of an inch thick. The larch should rise at the same distance as the Scotch pine; but the seeds being generally more or less injured in separating, many do not come up, and they are therefore sown thinner than the other.

6990. The seeds of the spruce fir are to be treated like those of the Scotch pine; and the balm of Gilead
fir-seeds, like those of the larch, only the covering should not be less than half, nor more than three quarters of an inch.

6891. The seeds of the silver fir and pinaster require the same sort of treatment as those of the larch. "They must not be sown to rise nearer one another than in three in an inch. The covering should be a full inch thick, and performed with great accuracy: for if any of the seeds be left too lightly covered, or if any of them be too deeply covered, they will alike be destroyed." (Plant. Kal. 332.)

6892. The seed of the Weymouth and stone pines may be treated like those of the Scotch pine, but the former covered three quarters of an inch thick, and the latter an inch and a quarter. Sang states, that the only way to get stately trees of these, as of most of the pine tribe, is to sow them where they are to rise into timber.

6893. The white American spruce-seeds are smaller than those of any of the preceding kinds, and therefore require a lighter covering than of any of them. One fifth of an inch is quite sufficient. They should be sown on a piece of fine dry sandy loam, and be covered with earth of rotten leaves of trees to the above thickness, by siting it upon them. (Plant. Kal. 533.)

6894. The seeds of black and red American spruce fir are very small and tender. They are still smaller than the seeds of the white American spruce, and therefore require a covering still lighter than mentioned for it. The black and red American spruce should be sown on rich boggy earth, which has been manured by adding manure and lime, as possible. The seeds are chiefly a yellowish or brownish color, and a sprinkling of white sand answers best. This should be sifted over the seeds with a fine sieve. Neither of these American spruces will allow the roller to pass over them previous to sowing. The whole of them should be shaded from the mid-day sun in the time of coming up, and for some time after, by means of hoops and mats; the fir branches stuck in the opposite alleys, so as to form an arch over the beds." (Plant. Kalen. 332.)

6895. Cedar of Lebanon seeds should be sown in boxes of light sandy loam; or on a spot of properly prepared well sheltered soil, and covered half an inch; the red and white cedar-seeds may be similarly treated, covering a quarter of an inch thick. Arbor-vitae seeds will come up best under a frame or handglass; they should be sown on light sandy soil, and covered a quarter of an inch.

6896. The strictest attention should be paid to the foregoing directions, both in regard to quality of soil, and the proper interval between the covered seeds. The seeds vary in their mode of germinating, some emerging immediately, others slowly; but they are all very tender in infancy. The raising regular crops of this tribe is, therefore, justly reckoned the masterpiece of nursery culture in the open ground; and is supposed to be best understood in the northern counties.

6897. Transplanting. This tribe benefit less by transplanting than the non-resinous trees; and therefore where circumstances admit, the better plan is, after the seedlings have stood two years in the seed-bed, to remove them where they are finally to remain. The exceptions are those sorts which are transplanted into pots, as the cedars and cypress, and some of the more delicate pines, which may be kept in the nursing state, in pots, several years, as their roots can be turned out entire. About the middle of April is the proper time for transplanting all the resinous tribe, excepting the larch; for, as this tree pushes up earlier than the others, it should be transplanted in February and March. The first operation common to all seedlings is to loosen the roots of the plants in the seed-bed with a fork, so as, when drawn out by the hand, they may come up with all their fibres entire. The ground, which must be mellow, need not be so rich as for sowing the seeds; being previously prepared, they should be immediately planted in the trench manner. (2085.) The Scotch pine is generally planted in lines twelve inches apart, and the plants a foot distant in the lines; if intended to remain two years in the lines, they should be placed six inches apart in the line; but they always rise with the best roots, after being only one year transplanted. The spruce and balm of Gilead fir should generally be transplanted at two years; but, if weak in the seed-bed, may remain till the third year. They should be planted at the same distances as the Scotch pine, in humid rich earth. The silver fir may be treated in the same manner, but it requires rather more space. If to be nursed only one year, they may be planted in lines nine inches apart, and at six inches' distance in the lines; but if to remain two years, then fifteen inches between the lines, and eighteen inches in the line will be necessary. The Weymouth pine should be transplanted at two years into a well pulverised, rich, and sub-humid soil, where it should remain two years before final planting; distance between the lines twelve inches, and from plant to plant eight inches.

6898. The pinaster and stone pine generally rise to well sized plants the first season after sowing, and should then be transplanted into a rich well comminuted soil, rather sandy and dry, at nine inches between the plants, and seen sixteen inches apart in the lines. After remaining there one year, they should be removed to their final situation. Great care is requisite in moving these plants, especially the stone pine, which sends down very long roots.

6899. The white American spruce, after remaining two years in the seed-bed, should be nursed two years in the dibble-bed, in lines distant twelve inches, and the plants six inches apart in the lines. The black and red American spruce are much more delicate than the white. After being two years in the seed-bed, they should be planted out in beds of sandy or subpeaty soil, at six inches apart, to stand for one year; at the end of this period, they should be lifted and planted in rows at the same distances as the white American spruce.

7000. The cedar of Lebanon, when one year old, should be lifted and planted in pots of the finest soil; or in lines, at the same distance as the silver fir; after being two years nursed, it should be removed to its final situation. The spruce may be planted at a greater age, unless pots were used, which is the best method. The red and white cedars and cypress may remain two years in the seed-bed, and then be treated like the cedar of Lebanon.

7001. The larch may be moved from the seed-bed into the nursing lines, at one or two years. The soil to be used should be prepared by a cross ploughing, and very thoroughly dug in the preceding season; but they should never be planted in land newly manured with fresh dung. One year's seedlings, to be nursed one year, should be planted four inches apart in the lines; but if to stand for two years, five inches, and fifteen inches between the lines. The two years' seedlings should be sized, as in the seed-bed they never all rise to the same height; the larger size may be placed six inches apart in the lines, and twelve or fourteen inches between the lines, to stand one year; the smaller, at five inches, and a foot, for standing the same period: they should then be removed to their final situation.

7002. Care of the roots. No description of tree-plants receive so much injury from the loss of roots;
from the roots being exposed to the air by being kept long out of the soil; or from compression and exclusion of air and moisture by being kept in close bundles, or thick layers, as those of the resinous tribe; they should therefore be finally planted as soon as possible after removal from the nursery; and, indeed, whenever it is practicable, no more should be taken up in one day than can be planted that day or the next. Nor are any plants more easily deprived of the vital principle, by packing and carriage either by sea or land; though, being all evergreens, excepting the larch, they do not readily show it. This has been stated to us, by experienced planters in Wales and other parts of England, as the reason why so few trees are finally produced from the immense numbers of Scotch pine and larch fir annually sent there by the Scotch nursemens.

7003. Pruning is not required by any of the resinous tribe in the nursery, unless to pinch off a contending leader, or amputate a bruised part of the root or top.

Sect. II. Trees and Shrubs bearing Nuts, Acorns, Masts, Keys, &c. their Sowing and Rearing.

7004. The principal hardy trees bearing nuts, acorns, masts, &c. are the following:—

<table>

7005. Gathering and keeping. These being gathered, if circumstances permit, should be immediately sown; but where this cannot be done, or where they are to be sent to a distance, they should be thinly spread in an airy loft till thoroughly dried, when they may be preserved till spring in bags or barrels, or sent off to any distance in these or other packages. When the seeds of the ash, sycamore, platanus, and hornbeam, are only to be kept for the purpose of spring sowing, the best plan is to take them to the rotting-ground (6979.), mix them with their bulk of dry sand or ashes, spread them in a stratum of ten inches in thickness, in the form of beds, cover with sand to the same thickness, and leave them in that state till wanted for spring sowing.

7006. Sowing. The bedding-in manner (2091.), or by drills, may be adopted for all the kinds. Acorns, horse and Spanish chestnuts, almonds, and hazel-nuts, should be sown in February, in strong loam, in good heart and well comminuted: the seeds should be placed half an inch apart, and covered two inches thick. Walnuts require a similar soil and covering, but should be placed two inches nut from nut. Ash-seeds will come up in soil of middling quality, but it should be well dug; and in an open situation, that the plants may not be drawn. Place the seeds half an inch apart, and cover one inch. Sycamore-plants when young being liable to be killed by the frost, the seeds should not be sown till the end of March or beginning of April; they should be sown in exposed, dry, sandy soil, an inch apart, and covered one inch in thickness. On rich moist land they will rise so tall and soft, that the extremities of their shoots will not ripen in autumn, and the plants will in consequence be unfit for use. Beech-plants, when newly risen, are still more tender than those of the sycamore kind, and therefore should generally be sown in April, but not later than the middle of the month; for if very dry weather set in, they will not rise till the following spring, and so have a great chance of them perishing by the frost. The soil should be tender and rich, previously under a culinary crop with dung; and it should receive a small dressing of well rotted manure previously to digging for semination. The seeds should lie an inch apart, and be covered a full inch. The best time for sowing the hornbeam is in October; but it may also be sown in February: the soil should be light, but not very rich; the bed form answers best: the seeds should lie half an inch apart, and be covered half an inch in thickness. The plant is seldom raised from seeds; but when this is done, a soft peat-earth soil is the best, and the covering should not be more than a quarter of an inch. The seeds of the bladder-nut, if sown as soon as gathered, will come up the following spring; if not, a part will not rise till the second year: sow in light rich soil, and cover an inch and a half deep.

7007. Transplanting. The operation of loosening the plants, sorting them into sizes, and pruning their roots and tops, require to be first performed. As these plants have generally long and strong tap-roots, these require to be cut in the operation of loosening; which, for this purpose, must be performed with a sharp spade, and care taken in thrusting it down, that the root is not cut too high; care should also be taken to preserve uninjured all the lateral fibres. In sorting the plants into two or three sizes, the fractured tap-root of each must be cut smoothly off with a sharp knife, and any side shoots on the stem cut close off. If the plants cannot be immediately planted, they may be laid in by the heels, or shoughed; that is, thickly bedded in the bedding-ground (6979.) till wanted. Here they may remain in layers not more than three or four inches thick, for a month or two in the winter season; and for a week or two even in February and March. None of the kinds should remain in the seed-bed longer than two years; but in drills they may remain three years; and more especially if the operation of tapping be performed; that is, cutting through their tap-roots about eight inches below the surface. “This is most effectually and readily done by two men with 3 R.
sharp spades; *cutting* or cutting the ground obliquely with their spades, on each side the line at once, and exactly opposite to each other. After this operation has been performed, the plants should be made firm, by a person treading the rows with a foot on each side. These kinds, so tapped, will, in the course of the following season, in consequence of being thus root-pruned, push many more fibres on the upper part of their roots, than they otherwise would have done; and thus will the plants be better fitted for being transplanted into shallow soils, or indeed into any soil, than they would have been by being allowed to remain in the ground untapped till the time of lifting.”

(Plant. Ed. 135.)

7008. Trench-planting is decidedly the best for all plants to be placed in lines; but more especially for ligneous sorts. Dibbing in is an easier and more rapid mode; but by trench-planting the fibres are spread out and regularly disposed on each side of the main root; whereas, by dibbing, as Sang observes, they are “huddled together into a hole probably not more than an inch and half in diameter.” Dibbing, however, may be adopted in the case of such seedling trees as have been robbed of most of their fibrous roots, by being pulled out in thinning beds intended to stand for two years.

7009. *The age at which most of these sorts should be transplanted* is one year; and the soil most desirable for removing them to, is the same as recommended for the seed-bed. The distances between the lines and the plants in the line depend partly on their kinds, but principally on the length of time they are to stand before retransplanting or final removal. The larger-growing broad-leaved sorts, as the chestnuts and walnuts, to stand only one year, should not be nearer than eighteen inches by six inches; and the oak, ash, beech, &c. not nearer than fourteen inches by three inches; if to stand for three years, the interspaces may be two or three inches more; something depends on the openness of the situation, and a good deal on the soil. The judicious nursery-gardener will consider all the circumstances, and adopt such variations of the ordinary distances as shall produce plants with well ripened shoots, and numerous fibrous roots.

7010. **Pruning, culture, and taking up for final planting.** When the plants are to remain two or more years in the nursery lines without removal, dig the ground between the rows in winter. At midsummer cut close off the lower side shoots; some defer this work till winter; but, besides the loss of sap avoided by midsummer pruning, the wounds heal the same season. In taking up for final planting, such plants as have been trench-planted must be loosened on the side which was solid at planting; if they have been in training for several years they should be lifted by throwing out a trench on one side, fully to the depth of the roots, and then putting in the spade on the opposite side, so as to get below all the roots.

**Sect. III. Trees and Shrubs with berried Stones, their Sowing and Rearing.**

7011. The principal hardy trees with berried stones are the following:—

Sorbus aucuparia, August

— domestica, November

— aucupifolium, November

— aucuparia, November

Pyrus amygdalifolia, November

Prunus avium, November

P. domestica, November

P. avium, October

Rhamnus catharticus, October

R. frangula, September

— communis, November

Laurus nobilis, November

— ceratocarpa, October

Rhamnus catharticus, October

Prunus padus, August

— lusitanica, September

— nigra, September

— spinosa, October

— pseudoplatanus, August

— hypermedia, August

— aceraria, September

— rhamnus, November

— amelanchier, November

— helix, October

— japonica, November

— vitellina, May

— mespilus, October

— pyracantha, November

— amelanchier, November

— phillyrea, November

— juniperus communis, October.

7012. **Rotting.** The whole of these when gathered, require to be taken to the rotting-ground; mixed with their bulk of dry sand or ashes, laid in beds of ten inches in thickness, and then covered with ten inches of sand, light sandy earth, or ashes. Here some sorts, as the holly, will require to remain two years; the haw, mountain ash, and yew, one year; and the other sorts, one winter, or till the following February. During this time the beds of each kind should be uncovered, carefully turned over, and the covering replaced. The advantage of rotting off their exterior covering in heaps rather than in the soil, where they are to germinate, is the saving of ground; for though some of the holly and haw, for example, will come up the next or the second season after sowing, yet, by keeping them one or two years in the rot-heap, we are sure all the seeds will germinate the same spring in which they are committed to the soil.

To the above general remarks, the gean forms an exception; for if sown immediately after being gathered in July, it will come up the following spring; but it will keep in the rot-heap a year. When any of these seeds are to be sent to a distance, instead of being carried to the rot-heap, they are spread thin in lots, dried and packed in barrels; great care must be taken that they are sufficiently dried, otherwise putrescent fermentation will commence, and the vegetative principle will be destroyed by the heat evolved.

7013. **Sowing.** The season is generally February, and the manner by *bedding in*, as before. The haw, the most important of this class, should be sown in the lightest richest land in the nursery; and if not very rich, some dung may be added. Sow in beds three feet four, or three feet six inches apart; the seeds should lie within a fourth of an inch of each other, and be rolled with a roller of fifty or sixty pounds' weight, and exactly the breadth of the bed, previously to covering, which should be one inch deep. If the seeds are too moist to admit of drawing a roller over them, heat in the seeds with the back of the spade. This operation of rolling in seeds not only fixes them in their places, so as to admit of applying the covering with greater freedom, but by consolidation is calculated to retain moisture, exclude too much air, and thereby promote germination. Holly and yew seeds should be sown on rich friable soil, shaded by a wall or by wattled
hurdles, or other means, from the mid-day sun. The distance is the same as for laws; they should be rolled, or beat in, and covered not more than half an inch. If previously rotted for two years, they will all come up the following May; but if only one year in the rotting-bed, a part will not come up till the second year: in this case they should be sown thin, as the growing plants will impede the others in breaking through the soil. Mountain ash seeds require a fine and rather rich soil; the seeds should not lie nearer than an inch, and the covering should be only a quarter of an inch. The gean should be sown, as soon as gathered, in deep sandy loam, the pulp being previously bruised; it need not be very rich, but must be dug deep before sowing: place the seeds an inch apart, and cover three quarters of an inch thick. Gean-stones, which have been preserved in the rotting-ground for spring sowing, will not come up regularly the summer following, but a part will lie till the second spring. The advantage of sowing as soon as gathered, is therefore obvious. Great care should be taken not to sow the cherry for the gean, as the former is not nearly so well calculated for a timber-tree. The seeds of the common and Portugal laurel, laurel-bay, mezereon, spurge-laurel, phillyrea, and the like, should be sown as soon as gathered, in rich soft soil, on a dry bottom: the seeds should be an inch apart, and be covered an inch. During the severest weather of winter, it will be advisable to protect them by hoops and mats. The seeds of the service, buckthorn, bird-cherry, and other species of prunus, rhhamnus, and mespilus, may be treated like those of the laurel, but will not at all require so deep a covering, nor will any of them require protection in winter.

7014. Transplanting. What has been advanced on transplanting plants from nuts, keys, &c. will apply here. Most of these species being smaller, will not require so great distances between the rows and plants. All the deciduous sorts may be transplanted in February or early in March; and all the evergreen species from the middle of April to the middle of May, and during the month of August. The greatest care will be requisite in lifting evergreens from the seed-bed, where they have been already once moved, so as not to injure their fibres; and on no account should more be taken up at a time than what can be planted the same day. Select for them the soils most suitable to their natures (6974.), as far as the limits of the nursery will permit; and in general, rather prefer a shady situation, especially for the holly, yew, and all the laurales. Hollies having few fibrous roots should be frequently transplanted; but this is not necessary with the yew, which has fibres in greater quantity. In transplanting the deciduous sorts, prefer narrow spaces between the lines, and wider intervals in the rows, to wide rows, and plants crowded in the row. One year's seedling thorns, for instance, to be nursed one year, may stand nine or ten inches by two inches; if for two years, twelve or fourteen inches by three or three and a half inches.

7015. For pruning, culture, and lifting for final planting, see nut-bearing trees, &c. (7004.)

Sect. IV. Trees and Shrubs bearing Berries and Capsules with small Seeds.

7016. The principal hardy berry and capsule bearing trees are the following: —

| Tilia europaei, November | Cornus mascula, October |
| Pyrus communis, October | virginiana, October |
| Salix nigra, September | racemosa, September |
| Salix caroliniana, September | canadensis, September |
| Berberis vulgaris, September | Lonicera, various species, August |
| Buxus sempervirens, September | Jasminum fruticosum, October |
| Ligustrum vulgare, October | Lonicera japonica, November |
| Euonymus latifolius, November | Viburnum lantana, September |
| Viburnum opulus, October | Ribes grossularia, September |

7017. Gathering and keeping. As this class of seeds are only wanted in small quantities, the most convenient way of preserving them is in the seed-loft or root-cellar in dry sand. They should be frequently turned over to separate the seeds from the pulp and husks, and cleaned by sifting and fanning early in February. For sending to a distance, they are to be treated likeberried stones; or they may be separated and cleaned previously to deportation.

7018. Sowing. All of them require a soft and rather moist soil, with the exception of the box, which should have a soil rather sandy and dry. They may be sown in February, in beds, and covered not more than a quarter of an inch; and when the seeds first begin to vegetate, it will be an advantage to shade them from the sun, by wattled hurdles; place them across beds which lie north and south, and along those lying in a direction east and west.

7019. Their transplanting and future culture are the same as for the foreign division.

Sect. V. Trees and Shrubs bearing leguminous Seeds, their Sowing and Rearing.

7020. The principal hardy leguminous trees are as follow: —

| Cyttis alpinus, October | Colutea arborescens, October |
| Robinia pseudo-acacia, November | Cytisus nigricans, September |
| Robinia pseudo-acacia, November | Robinia pseudo-acacia, September |
| Robinia caragana, November | Robinia pseudo-acacia, September |
| Cornus emonis, October | Cytisus nigricans, September |
| Cornus emonis, October | Robinia pseudo-acacia, September |

7021. Gathering and keeping. These being collected are to be dried thoroughly in an
airy loft, and the pods being afterwards threshed or opened, the seeds may be preserved in bags or boxes till spring, or sent to any distance.

7022. Sowing. The season for sowing all of them is February; the soil should be light, deep, and sandy, and the seeds placed an inch apart, and covered three quarters of an inch thick. This should be particularly attended to in the case of the laburnum, the seeds of which, being generally sure growers, if they rise thick, they lose their leaves about midsummer, become mildewed, and die. Attention should be paid not to intermix the tree-laburnum (C. alpinus, W. &c.) with the shrubby sort.

Sect. VI. Trees and Shrubs bearing small soft Seeds, their Sowing and Rearing.

7023. The principal hardy trees with small seeds are as under:

| Ahinus glutinosa, November | Populus alba, May |
| Betulua alba, October | Salix alba, June. |
| Ulmus campestris, June | Salix fragilis, May. |
| glabra, June | Syringa vulgaris, October |

7024. Gathering and keeping. All these require to be gathered as soon as ripe, otherwise some are apt to drop out of their capsules, as the alder, birch, and lilac; and others to be blown away and lost, as the elm, poplar, willow, and sumach. They should be gathered perfectly dry, and spread thin in a airy loft, till fit to put up in bags or boxes, for keeping or deportation.

7025. Sowing. Most of the sorts may be sown immediately after being gathered, in which case they will be more certain of germinating; and a number of elms, poplars, and willows, will come up the same autumn. But as protection during winter will, in that case, become requisite, the better way, in general, is to defer sowing till March or April, when all the sorts may be sown in light rich earth, rather moist, and covered not more than half an inch. The principal tree of this class is the broad-leaved elm, which, where intended for two-year seedlings, which, in most cases, is the preferable age for transplanting, should be sown to rise at least two inches apart, as the plants grow with great vigor even the first year.

7026. Their transplanting and future culture are the same as directed for berried stones, keys, &c.

Sect. VII. Culture common to all the Classes of Tree-seeds.

7027. Insects and vermin. New-sown seeds of most kinds are greedily devoured by various descriptions of vermin. Mice attack "acorns, sweet chestnuts, hazel-nuts, walnuts, and holly-seeds. They not only eat them on the spot, but they carry to their retreats great numbers of the seeds of which they are most fond. The cheapest, and perhaps the most effectual trap for their destruction, is the well known but neglected fourth figure trap. (fig. 668.) The new-sown haws and mountain ash berries are prey to the chaffinches, green linnets, and other birds. If the quantity sown be not great, the beds may be hooped over and covered with small-meshed nets. But if a great breadth of ground be sown, it must be constantly watched after sowing. If the watching be vigilantly attended to, for a few days immediately after sowing, the seed will not need much more attention till they begin to break the ground; at which period the watching should be closely and regularly continued. As they are always the strongest and best-ripened seeds which rise first; it is therefore of much importance to prevent these from being picked up." (Plant. Kalend. 250.)

7028. Weeds. Before the tree-seeds come up a crop of weeds will probably have made their appearance; these are to be removed when young, otherwise drawing out their roots will materially disturb the vegetating seeds. "It not unfrequently happens, that the land in which fir and larch seeds have been sown, becomes battered by heavy rains. This will certainly happen if rain fall immediately after sowing before the surface become dry; but if it once be fully dried after sowing, and before the rain fall, it will seldom or never batter. Suppose, however, the seed-beds are battered, so that the tender seeds cannot rise with freedom, the best way to relieve them is to draw over them a wooden roller, stuck over with lath-nails at half an inch distance, and driven in so as to remain half an inch beyond the wood of the roller. The roller should not be more than thirty inches long and not more than thirty pounds weight. By drawing this roller along the one side of the battered bed, while walking in the alley, and returning with it over the other, an ordinary-sized bed will be completely relieved. Some people rake their battered beds, in order to enable the seeds to rise. This is a most dangerous and destructive method of relieving vegetating plants. From their tender state, the smallest twist breaks them over, and consequently destroys them. We have experienced much advantage from using
the light armed roller, here recommended. It is, however, much better when no such are required. The surest way to guard against the need of such means, is to work the land when it is in a proper condition, and to sow the seeds in such weather as that the surface after sowing will be fully dry before rain come on. There is no dispensing with this precaution, when it is wished to secure an equal and good crop of seedlings.” (Plant. Kal. 367.)

7029. Birds. In May the pines and firs will begin to pierce the ground with the husks of the seeds still on their tops, and then watching the birds becomes of the utmost importance; not one ought to be allowed to light on the beds; to prevent which will require unremitting attention from break of day till sunset, for five or six weeks, till the plants are all up, and have thrown off their husks. After the nuts, mast, and haws have come up, they are no longer in danger from mice, but they may be attacked by snails, and grubs of beetles and cockchaffers at their roots. These are to be hand-picked.

7030. Watering and shading. In June severe droughts very often set in, and these are very prejudicial to small seeds, especially those of the resinous tribe, when rising through the soil. At this time watering and shading may be applied with great advantage, provided the former is accompanied by the latter, and daily attended to from the time it is commenced till rain falls. The best mode of shading is by the wattled hurdle. By the end of July the seedling plants of most sorts will be out of danger, and excepting a few of the tender sorts specified as requiring protection in winter, or by a hand-glass or cold-frame, will require no other care but weeding till fit to be transplanted.

Sect. VIII. Of propagating Trees by Layers, Cuttings, Suckers, Grafting, &c.

7031. Layering is next to rearing from seeds the most general mode of propagating hardy trees and shrubs. The more common species of forest trees to which this mode is applicable, are the Acer Platanoides, pseudo-platanus, tartaricum, dascyarpum, opalus, negundo, and other species; Betula lenta, populifolia, and rubra; Fagus ferruginea; Platanus occidentalis and orientalis; Populus græca, monolifera, and canescens; Tilia alba, americana, europea, and pubescens; and Ulmus campestris, nemoralis, and suberosa. Some of these, as the populars and planes, are also propagated by cuttings; but layers make the strongest plants. Whenever seeds can be procured, however, it is best to propagate in that way, as likely to produce the largest trees. The other trees propagated by layers, will be found in our Encyclopaedia of Plants, and in the arboricultural catalogue; and also all the shrubs so propagated. The situations and distances for planting stools in the nursery have been already mentioned (6981.); and, as there is nothing peculiar in the operation of layering timber-trees or shrubs, we have merely to refer to the general directions as to layers and stools. (1993.) The young or preceding year’s shoots of all the sorts above enumerated, if layered in autumn or winter, will be fit for being detached and planted in nursery lines by that time twelve months. They should be transplanted into well comminuted soil, as far as practicable, suitable to the nature of each; the distances should be regulated by the size of the layers and the time they are to be nursed. For ordinary purposes layers need not be nursed more than two years; but for single trees and ornamental plantations, they should be several times removed, and close pruned, till they have attained six or eight feet in height. Evergreen trees and shrubs, as being more tender than the others, should be layered in March and April, and from August to October. Some sorts root most freely when the wood is in a succulent state; and of such the current year’s shoots are laid about midsummer. This is practised with Stuaria, Arbutus, Andromeda, Kalmia, Azalea, Magnolia, Alaternus, Phillyrea, Laurus nobilis and sassafras, Zanthoxylum, Pyrus japonica, &c. The same practice is adopted with other free-growing sorts that it is wished to multiply as rapidly as possible; as the Rosa (6546.), Hibiscus, Loniceræ, Aristotelia, Mespilus, &c. Layers of the last sorts made during summer from the same year’s shoots, will be fitted to detach by the winter or the following spring; of the other sorts seldom sooner than the second August or autumn; but even then a season is gained, as the layers of those plants made in autumn, generally require to remain two years before they have made sufficient roots. The layers of all evergreens should be removed at the proper seasons for pruning, laying, or transplanting that tribe; that is, in April and May, and in August and September.

7032. By cutting is the next most general mode of propagating trees and shrubs, and the common forest trees generally so multiplied are as follow: Platanus occidentalis and orientalis; Populus angulata, balsamifera, dilatata, græca, monolifera, nigra, pendula, and trepida; Salix all the tree species; and Sambucus nigra. These are also propagated by layers, and a few of them by seeds; which last, it should never be forgotten, is by far the best mode where timber-trees is the object. The numerous tribe of shrubs propagated by cuttings, will be found in the Encyclopaedia of Plants already referred to.

7033. The manner of forming and planting cuttings has been already described. (2063.) The season for deciduous and evergreen woody plants are the same as for layering; and as in the latter mode of
propagation, so in multiplying by cuttings, some sorts succeed best when the current year's wood is taken at midsummer; as for example, Laurus estivalis, benzoin, and sassafras, Bignonia, Euphorbia, Phleomis, Rosa, Santolina, &c. Cuttings of some of these sorts, made of year-old wood in spring or autumn, require to stand two seasons before they have made sufficient roots to admit of their removal; by midsummer cuttings one year is gained. The same practice may be applied to deciduous sorts; but the plants produced are not so strong as by cuttings of ripened wood. All cuttings require to be planted in a shady situation, and sandy soil, dry at bottom; but kept somewhat moist by occasional watering in dry weather; their lengths are generally made in proportion to the length of the year-old wood, but seldom exceeding six or eight inches. The shoots of some sorts, as poplar, willow, honeysuckle, &c., are divided into several cuttings of this length. An inch of the former year's wood is often preserved in autumn-made cuttings; but this is not essential; as more important points are, making a smooth horizontal section at a bud, and in planting, pressing the earth very firmly to the lower extremity of the cutting. Midsummer cuttings should in almost all cases be covered with hand or bell glasses. The elder, most willows, the Lombardy, and some other poplars, will grow from cuttings or truncheons of several feet long, and of several inches in diameter. This method is occasionally adopted, when it is requisite to form extensive some rough plantation, to serve as a hedge or screen along an outward boundary. Cuttings for this purpose may consist of long slender rods of one or two years' growth, or as well of large truncheons or stakes from three to six feet in length. Further, the willow, in particular, will increase from large pole-cuttings of from six to ten feet, planted out at once to form either pollard-stems, or be trained into full standards. (Abercrombie.)

7034. The season for transplanting struck cuttings into nursery lines, are those already mentioned as the most fit for moving deciduous and evergreen trees, originated by other modes. (6983. to 7025.)

7035. By suckers. A few common trees, and a number of shrubs are propagated by suckers. The timber-trees are the Alnus glandulosa, Robinia pseud-acacia, Populus canescens, alba, and tremula, and Ulmus campestris. Of hedge plants, the common sloe and other wild plums, crabs, and pears, are, or may be so propagated. Various shrubs are propagated by suckers. Suckers make better trees than plants raised from cuttings, and also very good hedge plants. To induce a tree to send up suckers, the horizontal roots may be laid bare, notched in different places, and the earth mixed with sand and replaced; a powerful co-operative would be to cut the tree over by the surface, by which means all the sap would be employed in root-shoots. At the end of one, but sometimes not till the end of the second season, the suckers will be fit to slip off, or to separate by the knife with a part of the parent root attached; they may then be pruned as required, and planted in nursery lines.

7036. Grafting, budding, and inarching, are modes applicable to a few hardy trees and shrubs. The common forest trees are the Fraxinus americana, Populus candicans, heterophylla, and lavigata, Pyrus Aria, Quercus exoniensis, and Ulmus campestris and suberosa. These, and the ornamental trees and shrubs so propagated, are worked on stocks of the more hardy species of the same or of the next allied genus; and, probably, may be as durable plants for timber-trees as layers; by which mode the above enumerated sorts are also propagated. The stocks should be at least one year established, previously either to grafting or inarching; the operation for deciduous sorts is performed in spring at the rise of the sap. (2010.) Evergreens are almost always inarched either in April, or May, or August. Budding is performed in June and July, and is chiefly used in propagating the rose. (6533.) Some inarched sorts require two seasons before the scion can be detached from the parent plant.

7037. General culture and management of a private nursery. There is nothing material to be advanced on this head, but what has been already recurred to in this chapter, or in treating of the general management of the kitchen-garden. The first grand point is so to arrange the rotation of crops, that a crop of culinary vegetables shall intervene between every crop of trees, where that crop remains on the same soil two or more years; and between every two or three crops, where the crop of trees is lifted annually or the second year. The next thing is changing the surface of the soil, as in horticulture (2557.), weeding, stirring the surface, watering, shading, pruning, training, staking, and protecting. The important points of management are to procure the proper quantities of seeds or stools requisite to produce the quantity of trees to be annually furnished; to proportion the number of plants taken up daily to the number replanted in the nursery or forest the same day, and to attend to general order and neatness.

**Chap. IX.**

** Arboricultural Catalogue.**

7038. In our arboricultural catalogue we mean to enumerate, and shortly describe, the principal timber-trees which may be cultivated with advantage as such, in the climate of Britain, and also the most useful plants for hedges. We shall arrange the whole as resinous, hard-wooded, and soft-wooded trees; including in each section the hedge plants belonging to it, and in the last, the willows proper for osier-plantations; the general culture of the trees contained in each of these sections, has been given in chapters III. IV. VII. and VIII.
Sect. 1. Resinous or Coniferous Trees.

7039. The resinous forest trees are comprised in three genera belonging to the natural order of Coniferae, J.; viz. Pinus and Cupressus, Monoc, Monad. L., and Juniperus, Diec. Monad. L. The trees which are valuable as timber are comprehended under the genus Pinus, which comprises the three subdivisions of pines, larches, and firs. The first is distinguished by fasciculated leaves in different sheaths, but proceeding from the same sheathing base; the second by fasciculated leaves from solitary sheaths; and the third by solitary leaves. The branches of the whole genus are frondose or spreading, and caducous: those of the pine tribe spread the least; those of the larch tribe rather droop; and those of the firs are thin and much spread, and are peculiarly frondlike.

7040. The wild or Scotch pine, erroneously denominated Scots fir, is the Pinus sylvestris, L. (Lan. pin. l. t. 1.) Pin, Fr.; Keiffer or Führer, Ger.; and Pino, Ital. (fig. 669. a) It is an evergreen sub-conical tree; the foliage inclining to dark-blue or grey; shorter and broader than those of the stone pine (b); it is common in most parts of Europe, particularly the northern countries, and is the only species of the genus indigenous to Britain, being a native of Scotland, and naturalised in England and Wales. Under favorable circumstances it attains the height of seventy or eighty feet; it flowers in May, and the cones are fit to gather in December. The finest pine-woods in Britain are at Invercauld, in Invernesshire, and Gordon Castle, in Aberdeen shire.

7041. Uv. The timber of this tree is the red or yellow deal of the north of Europe, and is the most durable and valuable of any of the genus, unless we except the common larch. The universality of its application is known to every one. The Highland pine, Sang states to be not inferior to any imported, either in cleanness or durability, when it has been grown on a proper soil, and to a sufficient age. "But the pine is useless," he adds, "if bound to offices higher than that of roofing sheds, huts, lining of cars, lathing, or making of packing-boxes; while the natural or self-sown is fit for the finest purposes." Pontey considers the English-grown wild pine, if properly pruned and grown to a sufficient age, as likely to equal that of foreign growth. The tree is of great value as a nurse-plant; being propagated in Scotland, it is the birth of mountain ash, or mountain scrub (Pyrus hybrids), the most hardy timber-tree. Among its minor uses we shall only mention the production of tar by incision.

7042. Varieties. Of these, several have been noticed by botanists, and some consider the P. maritima (ep. Wild.) as nothing more. According to Sang, the variety commonly cultivated is least worth the trouble. "The P. sylvestris, var. montana," he says, "is the variety which yields the red wood: even young trees of this sort are said to become red in their wood, and full of resin very soon. The late distinguished Don, of Forfar, exhibited specimens of cones of each variety to the Highland Society of Science and Agriculture, and the Caledonian Horticultural Society. The variety preferred by Don, is distinguished by the disposition of its branches, which are remarkable for their horizontal direction, and for a tendency to bend downwards close to the trunk. The leaves are broader and shorter than in the other. They are distinguishable by their much lighter and beautiful glaucous appearance. The bark of the trunk is smoother than in the common kind. The cones are thicker, and not so much pointed. The plant is more hardy than the common sort, grows freely in almost any soil or situation, and quickly arrives at a considerable size." Sang says, he has seen trees of this variety at Cambuskenneth: and to be wished that he or some other competent nurseryman, in that quarter, would collect the seeds, and propagate it extensively. Thouin (Notes sur la Culture de Pinus, 8vo. 1819,) mentions a variety, which he calls P. syl. var. pin de Vigo, as affording the best timber. Whether the pine which forms the extensive plantations along the sea-coast at Bordescaux, and is called by foreign authors, Pinus maritima, be a variety of P. sylvestris or a distinct species, does not appear to be ascertained. The plant is tender, and easily killed by frost when young; but its timber is said to be of excellent quality. (Radcliff's Flanders, 250.)

7043. Soil and native site. This tree is naturally the inhabitant of mountainous districts, and of rocky, gravelly, or poor sandy soils. On the sides of mountains, in defiles and hollows, among stones and rocks, beside rapid rivulets or mountain torrents, it is found in high perfection; and if it stands in a place of great beauty. In many parts of the Scottish Highlands, where the soils are extremely various, and much mixed, the Scots pine has arrived at a good size, and often attained remarkable dimensions. In any kind of soil from a sandy to a clay, provided the substratum be rubble or rock, it will grow and flourish; but in wet tilly soils, it ought never to be planted; because whenever the roots have exhausted the turf or upper soil, and begin to perforate the sub-soil, the tree languishes and dies." (Plant. Kel. 65.)

7044. Inocili. The larva of Noctua Pineastra, L. (Xyleena, Hüb.) are deposited in the leading buds, and often perforate the young shoots, and leave the tree without a leader. The aphis pinei infests the tender shoots; and various dermestes live in the bark, and perforate the soft wood.

7045. The Corsican pine (P. laricio, P. S.) is a native of the mountains of Corsica and is nearly allied to the Scotch pine. This is a species in the Paris gardens, planted in 1784 and 56 feet high in 1821, thus described by David Don. "P. laricio is much handsome and finer tree than P. sylvestris with which however it stands in some respects agrees. It is of a more pyramidal habit, and its branches are shorter and more regularly verticillated. Its leaves are a third longer, and of a lively green, with their sheaths narrower and more acute. In its branches are quite straight, with depressed scales: and its bark is finer and much more entire. The enlightened Professor of Agriculture informed us, that it is equally hardy with P. sylvestris, and that its wood is much more weighty and resinosus, and consequently more compact, stronger, and more flexible. It grows wild on the summits of the highest mountains in Corsica. It seems to bear cones very freely, which ripen nearly about the same time as those of P. sylvestris.

7046. The pitch or red Canadian pine (P. resinosa) (Lan. pin. 20. t. 4,) is an Ameri-
can tree, introduced in 1756, not unlike the Scotch pine, and "receives its name from the color of the bark. From the high geographical range of this pine, it is well adapted to associate with the P. sylvestris. It has been imported in the form of masts into this country. Like the P. sylvestris, it affords an inferior timber on a damp and unsuitable soil." (Caled. Hort. Mem. ii. 367.)

7047. The pinaster or cluster-pine (P. pinaster, L.) (Lam. pin. 9. t. 5.) (fig. 669. b) grows to the height of fifty or sixty feet, with broader, thicker, and longer leaves than the common pine (a): the branches are also farther apart, and grow more horizontal than in that tree. As the tree advances in age it becomes naked and unsightly below; but the top grows highly picturesque, and may readily be distinguished in the landscapes of the Roman and Florentine painters. It grows naturally on the mountains of Italy and the south of France; in Switzerland it is cut into shingles for covering their houses, and also for making pitch. It flowers in April and May, and the cones are fit to be gathered in December. It was introduced in 1596, but never much cultivated, being less hardy and much less valuable as a timber-tree than the common pine. It is very picturesque, and well merits culture in that point of view. There are some large specimens at Culzean Castle, on the sea-coast of Ayrshire.

7048. The stone pine (P. pino) (Lam. pin. 11. t. 6, 7, 8.) (fig. 669. c) grows to a considerable height, with a straight stem and rough bark. The leaves are not quite so long as those of the pinaster, and are of a greyish or sea-green color. The cones are five inches in length, round, thick, and obtuse; the kernels are large, and frequently served up in desserts during the winter season in Italy and the south of France, and they are also much relished by the Chinese, for the same purpose. It is a native of the south of Europe; very common about Ravenna, and forming a distinguishing ornament of the villas of Rome and Florence. It was introduced here in 1570; but as the wood is not so resinous as most of the other sorts, it has been only cultivated for ornament.

7049. The swamp, Georgia, pitch, or long-leaved pine (P. palustris) (Lam. pin. 27. t. 50.) (fig. 669, d) is a valuable and a lofty tree in America, affording planks, which, imported in this country, are valued 20 per cent. higher than any other American timber excepting the black larch. The leaves are a foot or more in length, produced in tufts at the ends of the branches, and having a singular appearance. It grows in a warmer climate than most other pines; and if it were found to produce equally valuable timber in the low warm situations of England, which it does in America, it would be a most valuable tree. It was introduced in 1730, but has been very little cultivated.

7050. The Weymouth or New England larch, commonly called Weymouth pine, (P. Strobos) (Lam. pin. 31. t. 22,) (fig. 670.) forms the connecting link between the pine and larch tribe. It is one of the tallest of the genus, attaining in America the height of 100 feet and upwards. The bark is smooth and delicate, and the leaves soft and of a bluish green. Vast quantities of the timber, under the name of the white pine, are imported from America; but the tree seems to be of so delicate a habit, as to prevent our expecting it ever to become a large or valuable tree with us, especially in exposed situations. It was introduced in 1705, and has been a good deal cultivated, having formerly been supposed the most valuable tree of the genus, next to the common pine. The largest specimens are at Mersham-hatch, Sir E. Knatchbull's seat in Kent, and at Whitten Park in Middlesex.

7051. The cedar-larch, or cedar of Lebanon, is the P. cedrus, L. (Lam. pin. 59. t. 37.) Cèdre, Fr.; Cederbbaum, Ger.; and Cedro, Ital. It is distinguished from all other trees of the genus by its strong ramose branches, which, in some cases, deviate from the common character, and become irregular in shape, and permanent in duration. The general character of the shoot, even when the tree is young, is singularly bold and picturesque, and quite peculiar to the species. The tree is a native of the coldest part of the mountains of Libanus, Amanus and Taurus; but it is not now to be found in those places in great numbers. Maundrell, in his journey from Aleppo to Jerusalem in 1696, could reckon only sixteen large trees, though many small ones: one of the largest was twelve yards six inches in girth, and yet sound; and thirty seven yards in the spread of its boughs. The forest of Libanus never seems to have recovered the havoc made by Solomon's forty score thousand hewers: so that we have now, as Professor Martyn observes, probably more cedars in England than there are in Palestine. The tree is supposed to have been introduced here in 1693. The oldest specimens are
two in Chelsea-garden; but there are more magnificent ones at Whitton Park, Zion House, Pains-hill, Warwick Castle, and other places.

7052. Use. The tree has been very generally planted for ornament, and from its branchy head, and its aversion to pruning, it is not likely ever to become a valuable timber-tree in this country. When planted for ornament, it should, as Sang recommends, be seen in groves, and thus by proximity drawn up with few branches. Much has been said of the timber which begins its growth in the middle of November; as far as experience has gone, it is greatly inferior to that of the common larch, or the wild pine. Its great use is as a single tree in lawns, where it combines beauty and singularity in a degree not to be found in any other tree. It has also an excellent effect in the more perfect plantations, and one or two plantations will give force and character to the dullest front of round-headed trees, and effect a great deal even in the fronts and sky outlines of plantations with spiry tops. (fig. 560.)

7053. The common larch is the P. larix, L. (Lam. pin. 53. 35.) Larix or Méteze, Fr.; Lerchenbaum, Ger.; and Laricio, Ital. It is the only species of the genus, the leaves of which are deciduous; it rises to eighty or a hundred feet high, forming a narrow cone of small white-barked caduous, pendulous branches, with delicate drooping spray. It is a native of the Alpine mountains, on the north sides of which, in hollows and chasms, it attains to its greatest height and thickness, and most durable timber. In returning from Italy, by the Simplon, the silver fir will be found in great perfection in the hollows on the south side, the common Scotch pine on the summit, and the larch in descending to the Vallais. It appears to have been cultivated by Parkinson in 1629; and Evelyn, in 1664, speaks of a tree of good stature, “not long since to be seen at Chelmsford, in Essex, (also mentioned by Harte,) which sufficiently reproaches our not cultivating so useful a material for many purposes.” Harte, in his excellent essays, published in 1715, gives a figure of the larch, and strongly recommends its culture. It was first introduced into Scotland by Lord Kames in 1734 (Lam. pin. t. 35.), and afterwards in 1741, planted by the Duke of Athol at Dunkeld, and these last trees have prospered so astonishingly, and the timber produced from such as have been cut down, has so fully answered all the eulogiums that have been bestowed on it, that the larch is now considered on the whole, as decidedly the most valuable timber-tree, not even excepting the oak. Some of the first-planted larches in the low grounds, near Dunkeld, have grown to the height of one hundred and twenty feet in fifty years, which gives an average of two feet four and a quarter inches a-year. It is stated by the Duke of Athol, in a communication to the Horticultural Society, made in June, 1820, that on mountainous tracts, at an elevation of fifteen or sixteen hundred feet, the larch, at eighty years of age, has arrived at a size to produce six loads (300 cubic feet) of timber, appearing in durability and every other quality, to be likely to answer every purpose, both by sea and land. (Hort. Trans. iv. 416.) Professor Martyn (Miller’s Dict. in loco) has brought together a mass of valuable information respecting the history of the larch in this country, and its uses in others. That singularly accomplished agricultural writer, Dr. Anderson, did much to promote its increase by his essays and other works from 1750 to 1790; and subsequently the Bishop of Llandaff, Marshall, Nicol, Pontey, and Sang, have each, in practice, and by their popular publications, contributed to spread the tree; and now several millions are annually planted in the mountainous districts of the empire. The larch, Sang observes, passes all other timber-trees, for the first ten or twenty years after planting, and will arrive at a timber size in almost any situation or soil. It bears, he says, “the ascendency over the Scots pine in the following important circumstances: that it brings double the price, at least, per measurable foot; that it will arrive at a useful timber size in one half or a third part of the time, in general, which the fir requires; and, above all, that the timber of the larch, at thirty or forty years old, when placed in soil and climate adapted to the production of perfect timber, is in every respect superior in quality to that of the fir at a hundred years old. In short, it is probable that the larch will supersede the Scots pine in most situations in this island, at no very distant period.” The finest specimens of this tree are at Dunkeld, Blair, and Monzie, in Perthshire.

7054. Use. Much has been said of the durability of larch-timber in Italy: its resistance to fire, according to some (Matthioli,) and its great combustibility, according to others (Du Hame!) ; its durability under water (at Venice), and its not being liable to warp (Harte.) We shall confine ourselves to its uses as experimentally proved in Britain; and perhaps we shall do this with more effect by stating that it may be used for all the purposes for which the best foreign deal is applied; for many of those of the oak; and that it is more durable than any other timber when placed in a situation between wet and dry, especially if the bark be not removed, it being still more incorruptible than the wood. The bark is also of considerable value, having circumstances of great importance, since it is found that discharging a spar or more properly to felling is the best mode of seasoning the timber (595a), and preventing it from warping, or being attacked by the dry or wet rot. (5927. and 6953.) One property almost peculiar to the larch is, that the timber is exceedingly valuable at every period of its growth; so that a dead hedge of larch-houghs, or a hurdle wattled with larch-spray, will last longer than dead hedges or wattled hedges of any other species of tree. Planted in rows in exposed gardens it forms a useful hedge plant in point of shelter; but in this respect is deficient as a fence, and gets soon naked below. Rots, stakes, piles, rails, posts, and especially gate-posts, of this tree, are therefore more valuable than of any other; the spruce fir approaching the nearest to it in these respects. Turpentine is extracted from it in the Tyrol; but that being always injurious to the timber, can never be recommended for adoption in this country: it is also peculiarly valuable as a nursing-tree.

7055. Varieties or species. Of the P. larix, there is a variety with red and another with white flowers, one with cinnabar bark, called the Russian larch, and one with pendulous branches. There are also the
black larch (P. pendula) and red larch (P. micronurus), natives of America, by some considered distinct species; the timber of both of which is said to be harder than that of the common white larch. As these trees are only to be met with in the nurseries, originated by layers, they cannot be recommended to be planted in exposures to a great deal of wind. There are a few large colonies at Dagenham, however, and from these the trees will probably soon be propagated by seed, and a practical estimate be formed of their merits. There are some tree larches on the Athol estates, but they do not contain one third as many cubic feet of timber as the white larch at the same age. The wood is so ponderous that it will scarcely float on water.

7055. Soil and site. The larch will grow and attain a large size in every soil and situation, excepting in standing water; but a certain elevation of surface, or coldness of climate and inferiority of soil, is absolutely necessary to produce the timber in perfection. The quality of the timber of all trees is more or less affected by climate and soil, and the readers of the treatises on natural instances in 1806. (Treatise on Country Residences, ii.) Sang mentions a number as having occurred since 1812 (Plant. Kid. 98), and observes generally that he has "known it in many places make the most rapid progress and there is not an external sign of disorder, yet, for upwards of 50 years, the wood had begun to rot in the hearts of the trees; so that there was scarcely a sound tree over a large extent of ground; yet here, the oak, the chestnut, the elm, and the ash, amongst which the larch had been used as a nurse, are not only in the utmost vigor, but their wood is perfectly sound. Some larches in a similar soil and situation had attained seven feet each, and were quite hollow a good way upwars."

7057. Insects. The Coccus laricen, and the others mentioned as inhabiting the common pine.

7058. The Norway fir, or common spruce fir, (P. Abies, L. (Lam. pin. 73. t. 25.) Sapin, Fr.; Fichte, or Tanne, Ger.; Abiete, Ital.) is the first species of that section of pines in which the leaves are solitary. It is one of the tallest of European trees, attains from 100 to 150 feet in height, with a very straight but not thick trunk, and throwing out its spreading frond-like branches so as to form an elegant narrow cone of vivid green. It is a native of the north of Europe, and particularly abundant, as the name imports, in Norway; its timber being the white deal received from that country and the Baltic. It is supposed to have been introduced about 1548, and is still, and is more cultivated than any of the species of the genus, excepting the common pine and the larch. Some of the finest specimens are in Harefield Park, at Blenheim, and at Temple Newsam.

7059. Use. The timber is inferior to that of the common pine in durability and bulk; and being often knotty, is not strongly used for building purposes, excepting in the doubtful bearing of buildings where little weight is to be expected. Norway deal, however, is used for a great variety of purposes in building; and the entire trees are more prized than any other for masts for small crafts, for spars both for marine purposes and on land. What constitutes the value of this fir is, that its timber is equally durable at all ages, like that of the larch; and what renders it peculiarly adapted for masts, spars, scaffolding, poles, &c. is its habit of almost being perfectly straight, in every case, whether standing single or detached, growing perfectly erect and straight. The tree may be cut for rods, stakes, and scythe or other implement handles, when the trunk at the base is not more than two inches in diameter, and the bark being kept on, it will prove almost as durable as the larch. Pontey says, that poles of spuce are so far inferior to those of the larch, that they are more apt to crack when exposed whole to the influence of the sun and air; but in all other respects it is nearly equal to it, and in straightness surpasses it. The tree is peculiarly valuable as a nurse, from being evergreen, and closely covered with branches, by which radiating heat is retained; from its conical shape and rigid stem, by which it does not rot or split or crack at whatever age it is cut down; and from its being an excellent shelter for the most valuable timber. But, it will not, however, grow in situations where the common pine and larch will flourish. It is also an excellent hedge plant for shelter, where it is not in any degree exposed to the wind. In making turpentine, from which, by various preparations, turpentine and Burragundy pitch are formed. The tops or sprouts (sprutzten, Ger.) give the flavor to what is called spruce beer.

7060. Varieties and species. Linnaeus has five varieties of P. abies, but the principal are, the white (P. Abies alba), the red (P. robur) (Lam. pin. 43. t. 58.), and the black (P. Abies nigra, Lam. pin. 41. t. 27.) These are all natives of N. America, and their timber, which is white, possesses nearly the same properties as that of the European species. The white spruce rises only to 40 or 45 feet, with pale blue, leaf-like green. The black spruce is reckoned the most durable of the tribe. In America, the black spruce is used for heads in ship-building, where neither oak nor black larch can be easily obtained; these heads are not prepared from two diverging branches, as in the oak; but from a portion of the base of the trunk connected with one of the largest diverging roots. The timber of the red is universally preferred throughout the United States, excepting some parts of Canada, and indeed, extending from the banks of Nova Scotia, where it is also used for constructing casks for salted fish. It is chiefly formed from the decocation in water of young shoots of the black, and not exclusively from those of the white spruce, as supposed by Lambert, that the celebrated beer is prepared by fermentation, with a due proportion of sugar or molasses. The essence of spruce of the dealors is prepared by evaporating this decocotion to the consistency of honey.

7061. Soil and site. Pontey says it grows rapidly on every description of soil, from a very stilly loam, and better grown than any other, for every considerable degree of humidity, to a very dry sand, provided the situation be not very much exposed. Sang says, it grows in dry situations, but unless it is planted on protected places it never succeeds. It "should never be planted for the sake of its wood, excepting in masses or groves by itself; otherwise its timber is so coarse and knotty that it is hardly worth working; but in the massy way, if planted thick, and properly pruned and thinned afterwards, it may be trained to tall clean timber.

7062. Insects. The Coccus abietes, and occasionally the others which infest the common pine.

7063. The silver fir (P. Picea) (Lam. pin. 46. t. 30.) (fig. 671. a) is a lofty evergreen tree, forming a cone broader at the base, in proportion to its height, than the spruce, and displaying a more stable and majestic figure than any of the other firs. It is more thinly covered with frond-like branches than the spruce, and differs from it also in regard to the frondlets, which, when they grow old, and begin to decay, do not drop down as in that tree, but remain rigid till the last. The upper surface of the leaves is of a fine vivid green, and their under surface has two white lines running lengthwise on each side of the midrib, giving the leaves that silvery look, whence arises the name. It flowers in May, and the cones are ripe in December. It is a native of the Alps and Germany, was known here in 1603, and has been a good deal planted
as an ornamental tree. It grows faster for the first twenty or thirty years of its growth than any other tree of the genus, excepting the larch. Some of the finest specimens in England are at Woburn, in the evergreen-drive, planted by Miller. The tree called the grand silver fir there, measured, in 1810, nine feet ten inches in diameter, at four feet from the ground; it has a clean-pruned stem of seventy-five feet, and the estimated height is upwards of 110 feet.

7064. *Usk.* The timber is reckoned inferior to that of the common pine, and is not of much value till of forty or fifty years' growth. According to Sang, though till of late years planted only as an ornamental tree, yet there is, perhaps, none of the genus more worthy of cultivation for the sake of its timber. It is more prolific in resinous matter than any other fir kind.

7065. *Its soil and site* are nearly similar to those most desirable for the common spruce; but it requires a climate rather milder, and a more loamy earth. On poor sands, where the common pine and larch will thrive, it dies off in a year or two after planting. None of the genus are more majestic on a lawn; but its characteristic or natural situation, is in dells, and on the sides of sheltered rocky steeps.

7066. *The balm of Gilead fir* (P. Balsamea) (Lam. *pin.* 48. t. 31.) (*fig.* 671. b) is an American tree of much smaller stature, and more delicate habits than the silver fir. Its timber is of little value; nor can the tree be reckoned very ornamental, though frequently planted for the sake of variety. The balm or resin procured from it possesses no medical properties superior to those of common turpentine; but the tree during summer sends out a pleasing terebinthinate odor.

7067. *The hemlock-spruce*, or *hemlock-fir* (P. Canadensis) (Lam. *pin.* 50. t. 32.) (*fig.* 671. c) is a drooping, low, evergreen tree, which may be considered as entirely ornamental.

**Sect. II.** *Hard-wooded non-resinous Trees.*

7068. Of *hard-wooded trees* we shall give a few descriptive traits of the principal species; the most important of which are the oak, ash, elm, chestnut, and beech.

7070. *The common oak* (Q. robur) (Eng. *Bot.* 1845.) is a native of Britain. It grows to the height of fifty or sixty feet when in a heavy loam; flowers in April, and ripens its acorns in October and November. The most valuable variety of the common oak is said (Caled. *Hort. Mon.* iii. 376.) to be the pedunculata (Eng. *Bot.* 1845.), or the stalk-fruitied; by some considered a distinct species. It is distinguished from Q. robur by the marked circumstance of the acorns being placed on long fruit-stalks, whilst those of the robur are nearly sessile. Besides, the superior utility and hardness of the timber, the pedunculata oak is, in fact, the more magnificent of the two British sorts. Miller says, this variety of the Q. robur (and which he calls the *farnitio*) is more rare than the sessile-fruitied; but Professor Martyn says, this is not the case, and that the pedunculata is equally general as the other. It is observed by Du Hamel, that oaks in forests being propagated from the acorn, there are so many varieties that it is difficult to find two resembling each other. But, according to Prof. Martyn, the acorn of the sessile-fruitied is whitish and hard. From these and various accounts as well as our own observation, we consider ourselves justified in recommending to nurserymen and others, who gather acorns for seeds, to take effectual precautions that only the stalked sort be gathered.

7071. *The Turkey oak* (Q. cerris) (Du Roi, 2 t. 5 f. 1.), a native of the south of Europe, introduced in 1725. This species is distinguished by oblong, pointed, and frequently lunate leaves, jagged, and a little hoary on the under side. The acorns are small, and have rough prickly cups. The tree grows from forty to sixty feet high. There are several varieties, but the best is that called the Devonshire or Luccombe, from the county wherein it was raised. It is a tree of the Turkey oak grown in Devonshire.

7072. *Other oaks.* There are about forty species of exotic oaks introduced in this country, which may be considered as timber-trees, and are such in effect, in their native countries. Of these the greater part are natives of America; and it has been recommended (Caled. *Mem.* iii. 376.) to cultivate the Q. tinctoria or Ochre-iron on account of its bark, which affords a valuable yellow dye; all these species, however, are either too tender, or too scarce, or too dwarfish, and slow-growing, to warrant us in considering any other than the common and Luccombe oaks, as fit for the purposes of profitable planting.

7073. *Usk.* The oak cannot be considered so valuable a tree for general purposes as the common pine and larch; but its great strength and durability will probably long maintain its superiority in Europe, and in the other temperate regions of the globe, as a material for naval architecture. The timber is useful at every age, and more durable when of small diameter than that of any other of the hard woods; the value of the bark of young trees is greater than that of such as are old.

7074. *Soil and site.* It grows best in a deep clayey loam, not beyond a moderate elevation above the sea; but it will grow in any soil not marshy, not attaining, however, a large size in poor sands or at a considerable elevation.
7075. Insects. The egg-nest moth (Phalaena Quercus, L.; Lasiocampa, Leach) (fig. 672.) inhabits all the species, and its larvae sometimes denude entire branches. The small gnat (Cynips Quercus fodi, L. Diplopetes, Leach) (fig. 673.) pierces the leaves with its sting, and deposits its eggs in the exudated juices; the rise round it, and form a gall, which becomes hard, and in this the larva lives and feeds, and changes to a pupa. The oak-galls of commerce are so formed: the best are imported from Turkey and Greece.

7076. The ash is the Fraxinus, L. Polygami. Dioec. L. and Oleina, B. P. Fréne, Fr.; Ascho, Ger.; and Frassino, Ital. There are two species which may be considered as forest trees.

7077. The common ash (F. excelsior, L.) (Eng. Bot. 1862.) is a native of Britain, and grows from sixty to eighty feet in height, with a straight stem. It has pinnate leaves, which come out late in spring, generally from April 25th to May the 15th, and fall early in autumn; it flowers in April and May, and the female and hermaphrodite plants ripen their seeds or keys in November. Of this there is a variety, the simple-leaved (simplicifolia), and another, as a winter, and rather to be avoided by the profitable planter, as generally propagated in the nurseries by layers. Raised from seeds it produces pinnate-leaves.

7078. The white or American ash, F. Americana, W. (Mich. Arch.) This is a lofty tree like the other, distinguished by the whiteness of its bark, narrow leaves, and smaller seeds. It is found in Jersey and Pennsylvania, where it attains the height of eighty feet, with about three feet in diameter at the base. It is patient of cold, thrives in deep fresh soil, by the banks of rivers, and unites all the good properties of the common ash. There are two varieties, the red and blue: by some accounted distinct species. They are smaller trees, and present no advantages to the profitable planter over the two species mentioned.

7079. Use. The ash is unquestionably the most valuable indigenous timber next to the oak; and in some places, as copse, is more valuable than that tree. It is more especially used by the coachmaker and agricultural carpenter. The wood is useful when the stem is only three inches in diameter. Toughness and elan, together with the purity of its characteristics, and the tree grows the better. Timber from a tree of slow growth, and considerable age, is uniformly found to be more or less brittle, and therefore more or less unfitted for the purposes to which this tree is applied, especially shafts or poles of carriages. As underwood, it is fit to cut every seven years for crate-ware for the potteries, hoops, and hopper poles for making wood for firing or culture, but merely peripetric cutting forms excellent fuel, burning when green or new better than any other tree. "A few ash-pollards," Professor Martyn observes, "will produce many loads of lop, which makes the sweetest of all fires." The ashes afford more potash than those of most trees; and the bark is used occasionally for tanning, and will dye yellow.

7080. Soil and site. It will not thrive on thin soils, where the bottom is wet, nor in mossy earth or gravel; but in most others it will do well: and above all, in a hollow, where a friable loam has accumulated from the horizon of surrounding bleak hills and is drained by a rivulet. Such rocky dells and dikes abound in Derbyshire and Fifeshire, and in them the ash is to be found in great perfection. It will not thrive at a great height above the sea, nor in bleak situations anywhere.

7081. The elm is the Ulmus, L. Pentand. Dig. L. and Amencacca, J. Orme, Fr.; Ulmebaum, Ger.; and Olmo, Ital. There are two species which may be regarded as timber-trees.

7082. The English or narrow-leaved elm, U. Caprestris. (Eng. Bot. 1866.) (fig. 674. a) It is considered a native, or naturalised in England, by Sir J. E. Smith and others, but Dr. Walker considers it as brought originally from the Holy Land. It would be difficult to point out any situation in which it has the appearance of having sprung up from seeds; though it is said to be found in the woods of the north of England. It is certainly the loveliest of the deciduous trees of this country, being often found upwards of eighty feet high. It flowers in April and May, and ripens its seed in a fortnight or three weeks after the flowering. This species requires a dry soil, rather good than indifferent, and also a good climate. It does not thrive in the north of England or in Scotland, unless in good soils and moderately sheltered places. Professor Martyn says it is not found north of Newark on Trent. It grows to a great size in a short time. Evelyn says, in little more than forty years it will arrive to a load of timber. Of its specimens, the largest narrow-leaved elms he has seen, are in the Vale of Gloucester, and of these, the best is Pifé's elm, near the Baddington Oak. At five feet high it girls sixteen feet; at ten feet it throws out large arms, which rise seventy or eighty feet. Some of the elms in the old of St. James's Park are upwards of 200 years old. Boucher says, that he sold a line of elms, above sixty in number, which at twenty-four year's growth were seven feet in diameter, a foot above ground, and forty feet high.

7083. The Dutch elm (introduced by King William), U. Major (E. B. 2161.), U. suberosa, W. It is chiefly remarkable for its fungous rough bark, large rugose leaves, and rapid growth. The timber is of little use. U. Arborescens (U. globosa) (E. B. 2558.) (fig. 674. b) is easily distinguished by its smooth dark-colored bark, and by its leaves, which are nearly smooth on the upper surface. It is the most useful timber-tree of the genus, and is almost the only tree of the elm kind planted in Scotland, where it also forms stocks for grafting the Dutch and English elm. A new variety of this species has attestations. It is found north of Devon (Hart, Trees, vi. 146.) proposes calling the Downam elm. A very rapid-growing variety, called the Scaptamon elm, is in vogue in Durham and Northumberland. (Ag. Surv. of Durham, ch. x.)

7084. Species. The genus ulmus, like salix, is one of those whose species are so nearly related as to be often confounded. Linnaeus considered all the European elms as forming only one species. At present botanists make five British species, besides an equal number from America. The U. campestris and glabra, however, are the only sorts worth cultivating for their timber. (Don, in Hort. Tour, 538.) The elm is used in buildings where it may be continually dry or wet, as, in levees, piles, water-pipes, water-wheels, &c. It is also very generally used for weather-boarding, and for common cabinet-work. The knotty parts like those of the ash, are used for naves and hubs. The top and top make good fuel and charcoal.

7085. Soil and site. The narrow-leaved elm requires a light dry soil and warm situation, and will do little good in sand or gravel, in exposed places; but the smooth-barked sort is a very hardy tree, and will grow in thin clayey soil on retentive substrata better than most others. It will also thrive in situations elevated and exposed on all sides.
The beech is the Fagus sylvatica, L. (Eng. Bot. 1846.) Monoc. Polygan. L. and Amenataceae, J. Héret, Fr.; Büche, Ger.; and Faggio, Ital. It is a native of England, and grows in its natural soil and situation to sixty or eighty feet high. It is found congregated in forests, in chalky flinty soils, thrives well in sheltered bottoms; but not where it is exposed to the west. There are fine specimens of this tree at Castle Howard, Woburn, Newbottle, and Dalkeith Park. It is not so long-lived as the elm, nor will it grow in situations so much elevated as will the Scotch elms.

7089. Use. The timber is brittle, and decays soon in the air; but under water it is more durable. It is used by the millwright, turner, carver, last and wheel maker, chair and cabinet maker, and more or less in other branches. It is much used by bakers and in glass-houses as billet-wood; and the stack-wood forms an excellent charcoal.

7090. Soil and site. Dryness and some degree of calcareous matter are the characteristics of the soil in which the beech delights; and the declivities of hills facing the east or south are its favorite situations.

7091. The common hornbeam is the Carpinus Betulus, L. (Eng. Bot. 2032.) Monoc. Polygan. L. and Amenataceae, J. It is a native tree, nearly allied in habits and appearance to the beech, but is less lofty, and thrives in colder stiffer soils, and in rather more elevated situations. It flowers in April, and ripens its seeds in November. "Although Evelyn is perhaps too partial to the hornbeam, yet, raised from seed, it forms a tree of the first rate, equaling the common beech in magnificence; but unfortunately the hornbeam, like several of our best forest trees, may with ease, almost at any period of the year, be propagated from layers, and the usual consequences of this practice, follow,—a stinted, bushy, dwarf-like progeny. This tree, however, retaining its decayed, shrivelled, pale-russet leaves during winter, like the common beech, forms most valuable shelter planted in hedges." (Cul. Mem. ii. 397.)

7092. Use. Chiefly in turnery, being white and tough as the name imports. It is frequently used as a substitute for the beech.

7093. Soil and situation. A dry soil is essential, whether cold or chalky. It is a social tree, and found in natural copse-woods, as in Hertfordshire; but never at any great height above the level of the sea.

7094. The Spanish chestnut is the Castanea vesca, W.; Fagus Castanen, L. (Eng. Bot. 886.) Monoc. Polygan. L. and Amenataceae, J. It is the Chataignier of the French; Castanienbaum of the Germans; and Castagno of the Italians. It is one of the most magnificent of European trees, exceeding the oak in height, and equaling it in bulk and extent. It is doubtful whether it be a native of Britain, though it ripens its fruit in sheltered valleys even in Scotland. It seems a very long-lived tree, of which the best proof is the specimen on Mount Etna, two hundred and four feet in circumference. Boccher says, the shade of the chestnut, like that of the ash, is injurious to other plants. The leaves which continue late in autumn are not liable to be eaten by insects like those of the oak. The Spanish chestnut has been already described as a fruit-tree. (4745.) As a timber-tree it is used for the same purposes as the oak; though by some considered as more brittle when old. The roof of Westminster Abbey, and that of the Parliament House in Edinburgh, with many other antient works, are said to be constructed of it; but considering that it is not a native tree, this is extremely improbable; and it is much more rational to suppose, with Professor Martyn and Daines Barrington, that what is by many taken for chestnut, is only oak of a different grain. It is used by the cabinet-maker and cooper; makes an excellent coppice-tree for poles and hoops; the bark is equal in astrigency to that of the larch and mountain-ash for tanning; and the leaves and nuts afford food both for men and deer.

7095. Soil and situation. The soil in which it thrives best is a deep sandy loam, and the situation one somewhat sheltered. In Calabria, and on the Apennines between Florence and Bologna, where we have seen it in abundance, it does not attain a great size on the higher and more exposed parts of those mountains, but is, as Sang observes, a surprisingly magnificent tree in the hollows. Ponney says, "on sandy soils, where the oak would make but slow progress, I have seen the chestnut grow extremely quick, and therefore, in such cases, the latter should be used instead of the former."

7096. The walnut (Juglans regia) has been already treated of as a fruit-tree. (473.) Its timber, when of mature age, is valuable as a cabinet wood, and for gun-stocks, being light, hard, and durable.

7097. The common sycamore is the Acer Pseudo-platanus, L. (Eng. Bot. 303.) Polyg. Monoc. L. and Aereceae, J. It is one of our hardest native trees, and equal in magnitude with, though more tame in its outline and form than, the oak. It flowers in April and May, and ripens its keys or seeds in November. Its foliage is earlier than that of most trees, and its decadence is next to that of the ash. It is a quick grower, will endure the sea-breeze better than most trees, and is not liable to grow to one side when exposed to winds that blow chiefly in one direction.

7098. Use. The timber is chiefly used by the turner and millwright, and formerly, when earthenware was less common, it was in great request for trenchers and other table and household utensils. It affords a saccharine juice, like the sugar and other American maples, from which a wine may be made.

7099. The Norway maple (A. platanoides) is a tree common in the native woods of Lithuania; and in Norway it clothes the hills from the sea-shore to their summits. It grows to a large size, and its leaves die to a golden color. Its timber does not differ materially from that of the sycamore.
7100. Soil and situation. Both thrive best in a soil similar to that preferred by the ash, but will grow in all inferior soils, and exposed to the sea-breeze as well as at a great height above the level of the sea.

7101. The mountain ash is the Pyrus aucuparia, E. B. (Eng. Bot. 337.) Icos. Di-Pentag. L. and Rosaceae, J. It is a low and very hardy native tree, attaining the height of twenty or thirty feet, with a straight, clean, erect stem, and globular compact head. It flowers abundantly in April and May, and ripens its berries in August or October, according to the situation.

7102. Use. In profitable planting it is chiefly valuable as a nurse-tree, growing very fast when young, and enduring the most severe exposures. The timber is used by wheelwrights, and for other common country purposes: the bark is used by tanners; and the berries afford a dye. As an undergrowth it affords tolerable poles and hoops.

7103. Soil and site. It will grow in any soil, dry or wet; and as to situation, it is found on the seashore, and near the tops of the highest mountains. It seems to thrive best on the sides of most rocky dells and dingles.

7104. The whitebeam-tree (Pyrus aria) (Eng. Bot. 1858.) is a very hardy native tree, growing to the height of thirty or forty feet, with an erect stem. Its uses and culture are the same as those of the mountain-ash. Its white leaves, and coral berries mealy to the taste like those of Pyrus toriminalis (4768.), have a fine effect in autumn.

7105. The acacia, or locust-tree. — Robinia pseud-acacia, L. (Schmidt. Arb. 1. t. 32.) Diadelph. Decan. L., and Leguminose, J. This is a thorny fast-growing tree, of middling stature, a native of America, of no great beauty as a tree, but ornamental when young, and very well adapted for copse-wood and rough timber. It flowers in June and July, and ripens its seeds in September. The leaves come out late in spring, and fall off early in autumn like those of the ash.

7106. Use. The timber is much valued in North America, and said to be superior to that of the laburnum; "being close-grained, hard, and finely veined; and in America more valued by the cabinet-makers than their native orch, as ash, for timber whatever. Pursh, in his late valuable Flora, asserts, that being nearly incorruptible, it is equally useful for posts and gates. We are informed by a friend, that gate-posts of this timber, on a property near Baltimore, have remained fresh for nearly a century. The finely pin-nated leaves, and pendulous white odoriferous flowers, add greatly to its beauty. Its value is scarcely known in this country." (Caled. Mem. ii. 414.)

7107. Soil and site. It prefers a deep sandy soil, and rather sheltered situation; being very apt to throw up suckers from the running roots, and as it stoles freely, it seems particularly calculated for copice-woods. Beaton (Com. to Board of Agr.) has cultivated it in this way to great advantage.

7108. The birch is the Betula, L. Monoc. Poly. L. and Amentaceae, J. Bouleau, Fr.; Birkenbaum, Ger.; and Betulla, Ital. There are two species which may be considered valuable as timber-trees. The common birch (B. alba, var. pendula) (Eng. Bot. 2198.) is a middle-sized native-forest tree, distinguished by its white bark, fragrant leaves, and graceful penisle form. It grows in the coldest regions of the north, and farther up the sides of the British mountains than any other timber-tree. In the swampy grounds of Sweden and Russia it grows to a much greater size than in the more temperate climate of this country. It is of importance to cultivate the pendulous variety as a taller and more rapid-growing tree independently of its variety.

7109. The American birch, mahogany-birch, mountain mahogany, or cherry-birch of Canada, is the B. penta. (Mich. agr. 1820. p. 75.) This is a more lofty tree than the common birch, with a brown-colored bark spotted with white. "It abounds most in the middle states of Pennsylvania, New York, and the Jerseys, where it attains a height of seventy feet; but disappears altogether in the higher latitudes of the northern states, and is scarcely to be found in Nova Scotia. It is therefore likely to succeed with us in the moist and deeper soils of our Highland valleys, especially when closely associated with other trees. The probability of this is heightened by various facts already ascertained. The value of the timber, is well known to our cabinet-makers; and we have seen tables, bed-posts, and other articles of furniture made of it, equaling in beauty those of mahogany, which it resembles, when some time exposed to the light, the newly wrought boards being of a rose-color. Although of an exceeding quick growth, the grain being naturally close; it takes a fine polish in cabinet-work. We add to this, that the leaves, which appear early in spring, are said to possess a peculiar fragrance, which they retain when dried by means of a stove, affording, on infusion of boiling water, an agreeable dilute, superior to some of the common teas of commerce." (Caled. Mem. ii. 380.)

7110. The poplar-leaved birch (B. poplifolia) (fig. 676. a) and Hudson's birch (P. Hudsonii) (fig. 676. b) are elegant rapid-growing trees, and when once they are so common as to be propagated from seed, will deserve culture as timber-trees.

7111. Use. The timber of the common birch in England is chiefly used as fence-wood, fuel, and occasionally for hurdles. Sang observes, that being most frequently employed as a nurse for others of copice or variety. This tree, like the mountain ash, will grow in almost every kind of soil and situation.

7112. The wild cherry is the Prunus arium, L. (Blackw. t. 425.) Icos. Di-Pentag. L. and Rosaceae, J. Guigne, Fr.; Wild Kirschen, Ger.; and Ciriegio Silvatico, Ital. It is a native tree above the middle size, the timber of which is of considerable value. It thrives best in dry sandy loams; and in such situations, Sang observes, its timber becomes of most value. It is of peculiar beauty in spring when in flower, in August
when in fruit, and in autumn when its leaves change to a beautiful red and yellow. Its timber is chiefly used by the cabinet-maker and chairmaker.

7113. The tree-laburnum. — *Cytisus alpinus*, W. en. *Bot. Mag.* 176.) Diadelph. Decan. L. and Leguminose, J. It is a low tree, a native of Switzerland, cultivated chiefly for ornament, but affording also a valuable timber. For this purpose the variety or species (*C. alpinus*), with broad leaves and long racemes, is decidedly to be preferred, as being much more of a tree than the other. Sang says, it has a full claim to the characters of useful and ornamental; is beautiful when in flower, and may, in a grove, be trained to a fine stem of very considerable size.

7114. Use. The timber (the false ebony of the French) is much prized by cabinet-makers and turners, for its hardness, beauty of grain, and durability. The tree is frequently sown in plantations infested with hares and rabbits, who will touch no other tree as long as a twig of laburnum remains. "Though eaten to the ground in winter," as Bouchter observes, "it will spring again next season, and thus afford a constant supply for these animals, so as to save the other trees till of a size to resist their attacks. The timber has been sold for upwards of half a sovereign per foot." It becomes most valuable in light loams and sandy soils.

7115. The holly is the *Ilex aquifolium*, L. *Eng. Bot.* 496.) Pent. Monog. L. and Rhamn, J. Houx, Fr.; Steebbaum, Ger.; Agrifoglio, Ital. It is an elegant, shining, evergreen tree, rising from twenty to thirty feet high, affording a timber of considerable value, and much in use as an ornamental hedge plant. It is a native of Britain, of great longevity, and found growing in woods and forests, as an undergrowth to the oak, beech, ash, and fir. It thrives best in a free deep loam, rather light, as in Needwood Forest, in Staffordshire, and the fir-forest of Blackhall, near Aberdeen. It is a cheerful-looking tree from its shining leaves and coral berries, and peculiarly fit for ornament.

7116. Use. The timber, which is as white as ivory, is chiefly used in inlaying and veneering, and by turners and mathematical-instrument-makers. The straight shoots, of five and six feet in length, make excellent coachmen's whips. Birdlime is made from the bark by washing and separation of the woody fibre. Sheep and deer eat the croppings. It is the best of all hedge plants. It thrives best in cold loamy soils, and rather sheltered situations.

7117. The hazel (*Corylus avellana*), already treated of as a fruit-shrub (4752.), forms a hardy useful undergrowth in most situations, supplying hoops, crate-ware, basket-stuff, walking-sticks, rods, poles, withies, fence-wood, fuel, &c.; besides the fruit, where the soil is tolerable, is worth something, and an excellent charcoal is made from the stack-wood.

7118. The box-tree (*Buxus sempervirens*), L. *Eng. Bot.* 1341.) Monoc. Tetran. L. and Euphorbiaceae, J. Buix, Fr.; Buchbaum, Ger.; and Bosolo, Ital.) has some claims to attention as a valuable timber, being in considerable demand for inlaying, turnery, mathematical-instrumental, and wood-engravers' blocks. It thrives in any light soil and under the drip of trees. Raised from the seed it will attain the height of twenty or twenty-five feet, and be fit to cut down in thirty years. (Miller's *Dict.* in loco.) As an ornamental undergrowth and edging plant, it is of the greatest value.

7119. The elder-tree (*Sambucus nigra*), already treated of as a fruit-tree (4627.), forms an excellent nurse-plant in exposed situations, and a rapid hedge in most places. The wood is very hard, and used by the toy-makers and turners. When grown as a nurse, or for timber, it should always be raised from the seed.

7120. The hawthorn. — *Mespilus oxyacantha*, E. B. *Eng. Bot.* c. ic.) Ios. Di-Pentag. L. and Rosaceae, J. Aubépine, Fr.; Hagedorn, Ger.; Branco spina, Ital. It is a native shrub, of great importance as a hedge plant, and is also frequently introduced into narrow plantations as an undergrowth. It will not grow, however, under the drip of trees, and therefore, in a profitable point of view, is only to be considered as affording the impermeable, close, durable, and easily raised fences, called quickest-hedges. The timber of such plants as grow singly, and attain a tolerable size, is valued by the millwright and turner, and the roots by the cabinet-maker. It is often spoiled, Sang observes, through inattention after cutting; if it be allowed to lie in entire logs or trunks, it soon heats, and becomes quite brittle and worthless; it therefore ought to be instantly cut up into planks, and laid to dry. The haws and foliage afford excellent food for deer.

7121. Soil and site. It will not thrive in a wet soil, nor one very dry and poor, much elevated or much shaded; a free deep loam in an airy situation suits it best. For hedges it may be raised from cuttings of the roots, planted where they are finally to remain. Such cuttings are only to be procured in quantities
PRACTICE and Tilleid, If, and Marronier, so Eihenbaum, or or most a formed, various the nosegay,) speedily bleak elegantployed the growth, of aornament the timber. It flowers in April and May, and its berries are ripe in November. It is found in a wild state in bleak situations, and on a variety of soils, dry and moist. It is very common in ancient churchyards, in many of which it has attained a great size and age. Evelyn, and after him, Professor Martyn, have referred to a great number of examples of notable trees of this species.

7123. Use. The timber is used by the cabinet-maker for inlaying, and by the mathematical-instrument-maker, and whipmaker. It is sometimes used as a substitute for box and other hard woods, and every one knows it was formerly used for bows, and the spray as palm-leaves by the ancient Christians. It forms one of the best hedge plants for gardens, topiary work, &c. and for this purpose was much employed when the geometric style of gardening prevailed.

7124. Soil and situation. Almost any soil, not over-wet, will suit the yew, and it will grow on the bleak sides of mountains, and under the drip of trees.

Sect. III. Soft-wooded Trees.

7125. The soft-wooded timber-trees may be considered as characterised by great rapidity of growth, comparatively limited duration, and timber of inferior value.

7126. The horse-chestnut (Aesculus hippocastanum, L. (Schmidt. arb. 1. t. 38.) Hipp-tand. Monag. L. and Acerceæ, J. Marronier, Fr.; Marronienbaum, Ger.; and Marrone, Ital.) is a magnificent and beautiful tree, when in May it is covered with its digitate foliage, and fine large spikes of white flowers. It is of rapid growth, and speedily produces a considerable bulk of timber, which, however, is of no great value. Being highly ornamental as a single tree, and in the outskirts of plantations, it need never be planted in masses for timber. It was brought from the northern parts of Asia into Europe, about the year 1550, and was cultivated by Gerrard and Tradescant. As Gilpin observes, it is far from being a picturesque tree, its outline being that of a parabola: but all beauty is not picturesque beauty, and the foliage and flowers will ever advocate the cause of this tree, (which the Hon. D. Barrington compares to a giant's nosegay,) though “its leaves begin to drop early in summer, and make a litter around the trees during the remainder of the season.”

7127. Soil and situation. It requires a good, rather dry soil, and suffers materially from storms of every kind when planted in exposed situations. It used formerly to be much used as an avenue tree, especially by the French, and is particularly adapted for this purpose, and the margins of plantations.

7128. The lime. — Tilia Europea, L. (Eng. Bot. 610.) Polyand. Monag. L. and Tiliaceæ, J. Tilleul, Fr.; Lindenbaum, Ger.; and Tigli, Ital. This is one of the most beautiful, graceful, and fragrant of our native trees, rising to the height of seventy or eighty feet, and finely clothed with pendulous recurved branches, from the ground or the browsing line formed by cattle upwards. It is found wild in woods and grassy declivities, sends out its leaves in April, flowers in May, and ripens its seeds, though sparingly, unless under favorable circumstances, in October.

7129. Use. It was much valued by the Romans for its shade, and the multiplicity of purposes to which the timber was applied. It is now more a tree of ornament than of profit, but the timber is still used for various common purposes in general economy, and by the carver, turner, and musical-instrument-maker. It forms an excellent charcoal for gunpowder; and of its inner bark, macerated in water, is formed, in the north of Europe, the bass mats of commerce. This bark is called in Sweden and Russia, bast, whence, by corruption, bass. It is the fittest of all trees for avenues, and forms good tree-hedges. The famous Kowmo honey is made exclusively from the blossom of this tree.

7130. Varieties and species. There are several sorts noticed in our Encyclopaedia of Plants, but the best, both for effect and timber, is the red-twigged (T. Eu. var. corallina), and the broad-leaved American (T. Americana), which is a distinct species, distinguished by the larger size of the leaves, and elegy pendulous flowers.

7131. Seed and situation. All the sorts prefer a deep loam, and rather sheltered situation, for though patient of cold, they are much injured by storms. In Sweden, the common species abound among the debris of granite and trap rocks; and in Russia it covers extensive tracts of deep, soft, black earth. In bleak situations, where it is not covered by snow in winter at the roots, or sheltered by other trees, it will not thrive.

7132. The elder (Alnus glutinosa, W. (Eng. Bot. 1505.) Monace. Tetrand. L. and Amentaceæ, J.) is a middle-sized native aquatic tree of no great value, either as timber or ornament farther than that it will grow where few other trees will thrive, excepting the birch, poplar, and willow. It flowers in May, and ripens its seeds in September and October.

7133. Use. The timber is used in water-works, and by the turner, millwright, lastmakers, and others, as well as for common country purposes, and charcoal.

7134. The poplar. — Populus, W. Dodec. Dodec. L. and Amentaceæ, J. Peuplier, Fr.; Poppelbaum, Ger.; and Poppio, Ital. There are several species which may be reckoned timber-trees.
The varied earthly or woody poplar is distinguished from the common wild willow by its larger leaves, four, or five, oval leaves, dark above and downy under, and by the young shoots having a purple bark covered with white down. It is a rapid-growing tree, speedily attaining great bulk of timber, a height of 30 or 50 feet, and great extent of branches. The P. vitifolia seems a variety of this tree; and on the banks of the Vistula, particularly at Villeneuve, near Warsaw, grows to upwards of 100 feet high, with a clean trunk and small head.

The common black poplar (P. nigra) (fig. 677 b) is a native tree, of lofty growth, distinguished by its light-green leaves, slightly notched on the edges, and ash-colored bark. It is, by some, considered a mere variety of the alma, and for the purposes of profit may be so considered.

The trembling poplar (P. tremula) (fig. 677 c) and the common poplar (P. canescens) (d) are hardy natives; but being of less rapid growth than the species mentioned, are little cultivated as timber-trees. The common poplar in the northern counties may be frequently seen in the pollard stage, in hedges, where it furnishes lot for fuel, and sometimes for handles to hay-rakes, &c.

The Lombardy poplar (P. diltata) grows to a lofty tree, occupies little space, and is not very injurious by its shade. It will not thrive, however, in exposed situations, or in very indifferent soils. Some of the largest trees of this species are at Blenheim. Sang and Nicol say it seldom thrives in Scotland. The tall poplar (P. alba var. superba) (e) of the northern nurserymen, so strongly recommended by Pontey, is thus described by him, by comparison with a Lombardy poplar. "The leaves of both are very much alike in color, shape, and turn, the only difference being in the latter producing them somewhat larger than the former, though not near so large as the other poplars, whose leaves are of similar shape. They produce growth much more, and likewise much thinner upon the stem. The only other distinction necessary is the bark, which, on a stem or branch of from two to four or five years' growth, is always found smoother, and of a much darker color than any of the poplars that are at all like it in other respects. For this reason, it was brought from America, and disseminated by Dickenson and of Haaseaeanburn. Sang says, "many have ventured to assert, that it is merely a play on the vanity of possessing new sorts, and that it is not really distinct from those formerly cultivated." Pontey says, he measured, in December, 1813, a tree growing in the garden of Richard Atkinson, of Huddersfield, which, having been planted twenty-five years, being then about six feet high; the height is now about sixty feet, and contains forty-six feet of good timber. It grows on the side of a garden where the soil is light, and about a foot deep, upon a very coarse gravel, having been formerly a water-course." We could never find any poplar in general cultivation, or wild, in Italy, but the Lombardy and alba, and occasionally in the cultivated nursery-plant, in the Alpes, but Pontey, the tremula, the black poplar.

The black Athenian (P. grceca), black American or birch-leaved (P. betulifolia), the Canadian (P. monilbeta), and Carolina poplars (P. angustata), are all rapid-growing lofty trees, which, in favorable soils and situations, will produce a good bulk of heads and timber; but the hoary and the black Italian appear the best for the general purposes of the profitable planter. They are all short-lived trees; flower in March and April, and ripen their seeds from a fortnight to a month afterwards.

Use. The wood being soft is used by the sculptor, tanner, and toymaker, and also occasionally by the cabinet and musical-instrument maker, as a substitute for that of the lime. But no limited application of poplar-timber, like the above, can be depended on by the profitable planter, and, therefore, the safest way is to consider as it use for the common purposes of domestic and rural economy, and more likely to afford profit from bulk than quality. The bark of the black is so astringent, Sang states, as to be used far astrin. Alluding to the black Italian sort, Pontey says, "in that sort of planting which perhaps may be considered as most of all profitable, namely, that which adds to the comfort and consequence, and, of course, the value of a place, previously scantily furnished with that important appendage, a roof and blinds; this tree will proportionately be made to produce very considerable effects, while many others (highly esteemed) would produce them in prospect only. In short, for distant scenery, where wood, not species, is the immediate object, this plant, hitherto in many places a stranger, is clearly superior to all others. Of the hoary poplar, he says, Lord Sheffield "has lately made some floors, which, in appearance, are superior to any floor I have seen, whether of deal or oak; and, as to durability, I see no reason to doubt of that, if the density and weight of the article be considered, in connection with such testimonies as books afford relative to the point. Floors, however, are not the best of the many inferior purposes for which it is applicable; as it is certainly proper for almost every article of furniture usually made of mahogany. For the lighter descriptions of it, now so fashionable, it may be made a very good substitute, without any other addition to the natural color of its heart than the means canalizeurs generally resort to in their treatment of much wood; and with respect to the sap, and where more of color is required, the aquafortis stain will instantaneously produce it, so far as that it would be difficult to distinguish it from real mahogany. Indeed, it is equal to the best in color and smoothness of surface, and much superior to the plain or inferior sorts in those respects, as well in transparency and whiteness, and it has the further advantage over mahogany, and most other woods, that it takes but little either oil or rubbing, to produce upon it the sort of mellow shining surface so much admired in furniture that has been many years subject to proper attention." Of poplars and willows in general, he observes, "were we half as well apprised of the various purposes of which their timber might be properly applied, as we are of the quickness of their growth, I am persuaded they would then be considered as subjects worthy of the planter's attention.

Natural soil and situation. None of the sorts mentioned are ever found wild in very poor soils, but generally in such as are deep and moist, but not springy; by rivers and in bottoms, where the soil has accumulated from the surrounding heights, or alluvial deposits have taken place, for ages, poplars are found in the greatest perfection.

The willow. — Salix, L. Dice. Monan. L. and Amentaceae, J. Saule, Fr.; Weidenbaum, Ger.; Salici, Ital. There are two species which seem more immediately to merit cultivation as timber-trees, and several as fit for cultivating in osier-grounds.
7144. The Huntington or common white Lincolnshire swallow-tailed willow (S. alba) (Eng. Bot. 2430.) (fig. 678.) grows to a lofty tree, with a branchy stem, and tapering flame-shaped head. It seems common to Europe, being found pollarded by way-sides in Sweden, the south of Russia, and Italy. As a timber-tree it produces a great bulk in a short time; and as a pollard or coppice wood, on suitable soils, it is prolific in fuel, poles, and bark for the tanner.

7145. The Upland, or red-twigged willow of Pontey (Profit. Plant. 75.) appears to be a variety of the S. alba, being distinguished from it by its hoary or silver-like leaves, and deep red shoots. The timber and mode of growth appear to be the same as those of the Huntington willow, but being of slower growth, the former is to be preferred. Of the red-twigged willow of Sang, there are large trees near Dunfermline, upwards of 60 feet high.

7146. The Bedford willow (S. Rusceliana) (Eng. Bot. 1808.) (fig. 679.) is also a lofty bulky-headed tree, in general appearance and habits very much resembling the S. alba.

7147. Use. The timber may be used generally in rural economy, and the poles form a light and convenient hurdle. Pontey says, the timber is "considerably durable; a property which, it appears, may be much augmented by steeping some months in water, as is frequently done with osiers." The bark of all the sorts mentioned is found to be sufficiently astringent to be now generally used by tanners.

7148. The best willows for osier-grounds are the following:

7149. The common osier, Salix Pimpinelle. (Eng. Bot. 1808.) (fig. 680.) The leaves are long, waved at the edges, but not serrated; shining green above, and silvery underneath. The shoots grow long, straight, and tough, and are well adapted for the larger sorts of baskets, hampers, crates, and hamps.

7150. The avirced osier, S. stipularis. (Eng. Bot. 1214.) "The two-year-old shoots make excellent rods for baskets, cradles, bird-cages, and such articles; and the one-year shoots are used as fillings. The shoots are long, and nearly equal in thickness throughout their extent, and somewhat downy, or hoary, particularly at the tops or extremities. The leaves are alternate, with foot-stalks, long and narrow, somewhat nested on the edges, green and smooth above, and remarkable, resembling a pair of ears."

7151. The green osier (S. rubra) (Eng. Bot. 1145.) is an excellent basket willow. "The shoots are very long, tough, smooth, and of a grey color, occasionally inclining to purplish. The leaves are narrow and very long, from three to four inches, bright green on both sides, and serrated."

7152. The basket-osier, S. Forbignana. (Eng. Bot. 1344.) "The best willow for the finer sorts of basket-work. The shoots are of a yellowish ash-color, sometimes purplish; smooth, very flexible and tough. The leaves are alternate, on foot-stalks, from two to three inches long, somewhat serrated, chiefly towards the tops; dark-green above, and glaucous or pale-blush beneath."

7153. The long-leaved triamtrous willow (S. triandra) (Eng. Bot. 1454.) 4' is common in osier-beds, and its stools afford most excellent shoots for basket-work, long, slender, pliable and tough; they are smooth, of a brownish color, and towards the top they are fluted or grooved. The leaves are long, and closely and strongly serrated."

7154. The velvet osier, S. mollissima. (Eng. Bot. 1509.) "Its leaves are very smooth and green above, and very silky and soft beneath. Shoots long and very numerous but not tough; when allowed, however, to remain for two years, they make most capital rods."

7155. The yellow willow, or golden osier (S. vitellina), (Eng. Bot. 1329) produces "handsome shoots, of a yellow color and shining, and well adapted for basket-work."

---

**BOOK IV.**

**LANDSCAPE-GARDENING.**

7156. In landscape-gardening, the art of the gardener is directed to different objects, and some of them of a higher kind than any belonging to gardening as an art of culture. In the three branches hitherto considered, art is chiefly employed in the cultivation of plants, with a view of obtaining their products; but in the branch now under consideration, art is exercised in disposing of ground, buildings, and water, as well as the vegetating materials which enter into the composition of verdant landscape. This is, in a strict sense, what is called landscape-gardening, or the art of creating or improving landscapes; but as landscapes are seldom required to be created for their own sakes, landscape-gardening, as actually practised, may be defined, "the art of arranging the different parts which compose the external scenery of a country-residence, so as to produce the different beauties and conveniences of which that scene of domestic life is susceptible."

7157. What these beauties and conveniences are, must, in different ages and countries, depend on the state of society and climate; and, in the same age and country, on the
wealth and taste of individuals. This art would be a very simple one in rude ages and mild climates, when man had few wants, and scarcely any desires; but, like other arts, would become more intricate as mankind betook to more variable climates, and became more refined in habits and manners. Taking a view, as far as history permits (see Part I.), of the past and present state of landscape-gardening in all countries, the objects desired in the country-residence of a wealthy man, wishing to display his riches, are fundamentally the same. These were and are, adaptation to the habits of genteel life for the time being, as to matters of use and convenience; and distinction from the common scenery of the country, as to matters of taste or beauty in landscape. The first object would principally affect the mansion and accompanying erections for men or cattle; and these would, at first, be merely of greater dimension than those of the common mass of rustics; but, as society improved, they would be distinguished by more perfect execution, and appendages indicative of the habits of genteel life. The second object, distinction in the surrounding scenery, was and is effected by such dispositions of the common materials of landscape, as ground, water, trees, &c. as indicate the employment of art and expense. In early times, this would produce regularly level or sloping surfaces of ground, and water and trees bounded by straight or geometrical lines, which would distinguish the country-residence from the natural or open unclosed scenery around. In late or modern times, when the general face of the country was disposed in artificial forms, a contrary practice would be pursued, and natural-like scenery would be created for precisely the same object as in the other case; the display of wealth and taste, and the attainment of distinction.

7158. Hence the origin of what are called the geometric and natural styles in landscape-gardening, both evidently founded on the same principle, the love of applause and distinction. The first has been generally condemned as unnatural and absurd; and so it is, if we look upon it as an imitation of nature; but as it never pretended to this, but, on the contrary, was avowedly a display of the power of art over nature, it ought to be judged, like every other work of man, by the end in view; and if, as we have already observed (596.), it be considered as designed to distinguish the garden-scenery of the man of wealth from the common fortuitous scenery of the country in rude or less cultivated times and places, it will be found admirably calculated for that purpose, and just as natural to man as any other part of his habits or manners. But we will even go farther, and maintain that the geometrical disposition of landscape-scenery has powerful beauties, both of the inherent kind, as that of a long broad avenue, or of general or particular associations, as its suitableness to Gothic architecture, very ancient residences, &c. Disapproving, therefore, of that absolute preference of the modern or natural style, which totally excludes the other, we have, in treating of planting (Book III. Chap. IV.), not lost sight of the geometrical dispositions of trees; and we shall, in considering the present branch of our subject, notice also the dispositions of ground, water, roads, &c. peculiar to the geometric style. A knowledge of both will be desired by the liberal-minded practical designer; and the occasional adoption, in part, at least, of the ancient style, will be dictated by general good taste, as well as by the particular tastes of individuals, and the circumstances of peculiar situations. We shall consider, in succession, the principles of composing landscape; the treatment of the materials of verdant scenery; the union of these materials in forming landscapes; and the union of landscapes in connection with scenes of use and convenience in forming country-residences.

CHAP. I.

Of the Principles of Landscape-Gardening.

7159. The principles of landscape-gardening, like those of every other art, are founded on the end in view. "Gardens and buildings," Lord Kames observes, "may be destined for use solely, for beauty solely, or for both. Such variety of destination bestows upon these arts a great command of beauties, complex not less than various. Hence the difficulty of forming an accurate taste in gardening, and architecture; and hence, that difference or want of taste in these arts, greater than in any art that has but a single destination." (Elements of Criticism, 4th edit. vol. ii. 431.) Not to consider landscape-gardening with a view to these different beauties, but to treat it merely as "the art of creating landscapes," would thus embrace only a small part of the art of laying out grounds, and leave incomplete a subject which contributes to the immediate comfort and happiness of a great body of the enlightened and opulent in this and in every country; — an art, as the poet Mason observes,
7160. The ancient authors on architecture and gardening have rarely attempted to lay down any general principle of composition. Vitruvius hints obscurely, that the different parts of buildings, should bear some proportion among themselves, like that which subsists between the different members of the human body; that the quantities constituting the magnitudes of temples, should have certain ratios to one another, and he lays down canons for the individual proportions, and collective arrangement of the columns of the different orders. These, however, are not principles, but mechanical rules, formed on very limited associations. The same remarks will apply to the directions respecting the walks, walls, hedges, and borders of the ancient style, laid down by D'Argenville, Clarici, Le Blond, and Switzer. It is in the writings of modern authors, therefore, and chiefly from the enlightened investigations of the Rev. A. Alison, that we are to draw our information as to the principles by which the artists of the ancient style were instinctively guided in their productions.

7161. With respect to the modern style, considered as including what belongs to the conveniences of a country-residence, as well as the art of creating landscapes, Pope has included the principles under, 1st, The study and display of natural beauties; 2d, The concealment of defects; and 3d, Never to lose sight of common sense. Wheatley concurs in these principles, stating the business of a gardener to be "to select and to apply whatever is great, elegant, or characteristic" in the scenery of nature or art; "to discover and to show all the advantages of the place upon which he is employed; to supply its defects, to correct its faults, and to improve its beauties." Repton, whose observations on landscape-gardening bear on the title-page, to be "written with a view to establish fixed principles in these arts," enumerates congruity, utility, order, symmetry, scale, proportion, and appropriation, as principles, "if," as he observes, in one place, "there are any principles." Mason places the secret of the art in the "nice distinction between contrast and incongruity;" Mason, the poet, invokes "simplicity," probably intending that this beauty should distinguish the English from the Chinese style; simplicity is also the ruling principle of Lord Kames; Girardin includes every beauty under "truth and nature," and every rule "under the unity of the whole, and the connection of the parts;" and Shenstone states, "landscape or picturesque gardening" to "consist in pleasing the imagination," by scenes of grandeur, beauty, and variety. Convenience merely has no share there, any farther than as it pleases the imagination. Congruity and the principles of painting are those of Price and Knight; and nature, utility, and taste, those of Marshall. From these different theories, as well as from the general objects or end of gardening, there appear to be two principles which enter into its composition; those which regard it as a mixed art, or an art of design, and which are called the principles of relative beauty; and those which regard it as an imitative art, and are called the principles of natural or universal beauty. The ancient or geometric gardening is guided wholly by the former principles; landscape-gardening, as an imitative art, wholly by the latter; but as the art of forming a country-residence, its arrangements are influenced by both principles. In conformity with these ideas, and with our plan of treating of both styles, we shall first consider its principles as an inventive or mixed, and secondly as an imitative art.

Sect. I. Of the Beauties of Landscape-Gardening, as an inventive and mixed Art, and of the Principles of their Production.

7162. Works of art, Alison observes, may be considered, either in relation to their design or intention — to the nature of their construction for the intended purpose — or to the nature of the end they are destined to serve; and their beauty accordingly will depend, either upon the excellence or wisdom of the design, the fitness or propriety of the construction, or the utility of the end. The considerations of design, of fitness, and of utility, therefore, may be considered as the three great sources of the beauties of works of inventive art. They have been called relative beauties, in opposition to those of nature and imitative art, which are hence denominated natural or independent beauties. There is a third source of beauty common both to arts of invention and imitation, which is that of accidental beauty, such as is produced by local, arbitrary, or temporary associations. The beauties of objects, whether natural, relative, or accidental, are conveyed to the senses by the different qualities of matter, forms, sounds, colors, smells, and motion; but form is the grand characteristic of matter, and constitutes in a great degree its essence to our senses. In our remarks, therefore, on the beauties of inventive art, we shall chiefly consider design, fitness, and utility, in regard to form.

7163. The expression of design is displayed by such forms and dispositions, as shall at once point out that they are works of art. Thus regularity and uniformity are recognised in the rudest works of man, and point out his employment of art and expense in their construction. Hence the lines, surfaces, and forms of geometric gardening should be different, and in some degree opposed to those of general nature. Irregular surfaces, lines, or forms, may be equally useful, alike works of art, and, considered with reference to other beauties, may be more agreeable than such as are regular; but, if too prevalent,
they might be mistaken for the production of nature, in which case they would lose the beauty of design; but forms perfectly regular, and divisions completely uniform, immediately excite the belief of design, and with this belief, all the admiration which follows the employment of skill and expense. Ground in level or regular slopes, or in hills or hollows of symmetrical shapes; woods of right-lined boundaries; trees, and especially such as are foreign to the soil, planted equidistantly in masses, in quincunx, or in straight rows; water in architectural basins, regular canals, or fountains; walks and woods, of uniform width and perfectly straight; straight walls and hedges are easily distinguished from nature's management of these materials, and are highly expressive of the hand of man.

7164. Regular forms are satisfactory, Stewart observes (Philosophical Essays, 238.), "from the principle of a sufficient reason, adopted by Leibnitz. What is it, that in any thing which is merely ornamental, and which at the same time does not profess to be an imitation of nature, renders irregular forms displeasing? Is it not, at least, in part, that irregularities are infinite; and that no circumstance can be imagined which should have decided the choice of the artist in favor of that particular figure which he has selected? The variety of regular figures, it must be acknowledged, is infinite also; but supposing the choice to be once fixed about the number of sides, no apparent caprice of the artist in adjusting their relative proportions, presents a disagreeable and inexplicable puzzle to the spectator."

7165. Wherever symmetry "is useful to the soul, and may assist her functions, it is agreeable to her; but wherever it is useless, it becomes distasteful, because it takes away variety: therefore, things that we see in succession ought to have variety, for our soul has no difficulty in seeing them: those, on the contrary, that we see at one glance, ought to have symmetry; thus at one glance we see the front of a building, a parterre, a temple; in such things there is always a symmetry which pleases the soul, by the facility it gives her of taking the whole object at once. (Montesquieu.)

7166. The expression of design, in the progress of the arts, though at first difficult, becomes afterwards easy, and renders regularity and uniformity only expressive of common design. Hence, to confer a character of superiority in works of design, variety would be introduced; and as uniformity was the sign of design, so uniformity and variety would become the sign of improved or embellished design. "Considering, therefore, forms in this light as beautiful, merely from their expression of design, the observation of Dr. Hutcheson may perhaps be considered as an axiom with regard to their beauty, viz. that where the uniformity is equal, the beauty of forms is in proportion to their variety; and when their variety is equal, their beauty is in proportion to their uniformity." (Alison's Essays, p. 106.) To this stage, in the progress of design, may be referred the architectural ornaments introduced in garden-scenery, such as seats, buildings, statues, urns; and in the later stages of the art, serpentine walks, labyrinths, verdant sculpture, and many other improvements. The variety and embellishment thus conferred on gardens produced in time many absurdities, that we would not wish to see resorted to with a revival of the ancient style, unless in examples considered solely with a view to imitation. The sculpture of trees, however, might, when first introduced, be greatly admired, even by men of sense, for its novelty, and the discovery of a certain degree of skill in the artist; but as, in our times, they would neither be new nor meritorious, they could scarcely be consistently introduced with a view to embellish design.

7167. To present variety from degenerating into confusion, and as Professor Stewart characteristically expresses it, "puzzling the spectator," unity of intention must never be lost sight of. This, indeed, is necessarily implied in every work of art, since, without it, the slightest attempt at design would only end in a chaos of materials.

7168. Fitness, or the proper adaptation of means to an end, is the second source of the relative beauty of forms. Considered in relation to the parts of a building, it is generally denominated proportion, and refers to the adequate strength of certain parts to bear certain weights, &c. In the detail of the ancient, and in scenes of relative beauty in the modern style of gardening, it relates to the magnitude and situations of buildings, and other artificial objects, relative to natural ones,—to the extent of the different scenes or constituent parts of a residence, compared to the whole,—to the propriety and congruity of certain objects as ornaments,—and, in general, to the adequacy of means to an end, whatever these means or that end may be.

7169. Utility is the third source of the relative beauty of forms. None of the other beauties will compensate for the entire want of utility in any scene of architecture or gardening. Objects at first thought beautiful, soon lose this expression when they are found to be of no use; and others, with first impressions the most disagreeable, are felt to become beautiful as they are known to be useful. "This species of beauty," Alison observes, "is in itself productive of a much weaker emotion than that which arises from the different sources of ornamental beauty; but it is of a more constant and permanent kind, and much more uniformly fitted to excite the admiration of mankind." (Essays on
Taste, vol. ii. p. 201.) "To unite these different kinds of beauty; to dignify ornamental forms by use; and to raise merely useful forms into beauty, is the great object of ambition among every class of artists. Wherever both these objects can be obtained, the greatest possible beauty that form can receive will be produced. But as this can very seldom be the case, the following rules seem immediately to present themselves for the direction of the artist: — 1. That where the utility of forms is equal, that will be the most beautiful to which the most pleasing expression of form is given. 2. That where those expressions are at variance; when the beauty of the form cannot be produced without sacrificing its utility; that form will be most universally and most permanently beautiful, in which the expression of utility is most fully preserved." (Essays, vol. ii. p. 202.) Some of the various modifications of utility, as applied to country-residences, may be here enumerated.

7170. *For the purpose of habitation,* for example, good air and water, a genial climate, fertile soil, cheerful prospect, and suitable neighborhood, &c. are known requisites. Convenience must be joined to use, comforts to conveniences, and luxuries to comforts. Exercise, whether in the shape of walking, riding, or driving, requires to be provided for; and recreation, whether in the common field sports, athletic games, or in botanical, agricultural, and other useful, elegant, or scientific pursuits, must be kept in view: rural fêtes and amusements might also be enumerated.

7171. Accidental associations form the next class of relative beauties, and are "such associations as, instead of being common to all mankind, are peculiar to the individual. They take their rise from education, from peculiar habits of thought, from situation, from profession; and the beauty they produce is felt only by those whom similar causes have led to the formation of similar associations." (Stewart's Essays.) Among these may be reckoned —

7172. Classical and historical associations. The influence of the former in architecture is well known; the latter often adds charms to a spot, in no respect remarkable to those who are unacquainted with its history. Classical associations," Stewart observes, "have added immensely to our natural resources, but at the same time, warped our taste in various instances;" acquiring, as Alison adds, "a superiority over the more permanent principles of habituation, and determining for a time the taste of nations."

7175. National associations are also frequently at variance with such as are universal, and have, perhaps, greater influence than any other associations whatever. (Stewart's Essays.) They derive from the accidental associations, or such arrangements of natural beauties, to which we have been accustomed in our youth. Many particulars come under this head, which it would be tedious to enumerate; but one mode of vanity and selfish feeling deserves particular notice, as intimately connected with the business of the landscape-gardener. It is that which attaches to the spots on which our national heroes or famous men were born or raised, in men's minds, "rendering them alive to every trifling recommendation belonging to what is their own, while it blinds them to the most prominent beauties in the property of their neighbors." (Stewart's Essays, p. 408.)

7175. Appropriation, or such an arrangement as shall, either in reality or appearance, render all, or the greater part of what we see from a country-seat our own, is a consequence of personal associations. The simplest way of effecting this, is by shutting out all objects which do not correspond with the idea, by means of walls or plantations. A more refined mode is, by harmonising the scenery; by adopting some of the more remote situations (situations which are a part of our own territory and enjoy our neighbors, as seen from the house, or some particular points of view. According to Wheatley, "one property of a riding is to extend the idea of a seat, and appropriate a whole country to the mansion." For this purpose, he requires the road of the riding to be different from common roads in form and preservation, and distinguished by accompaniments borrowed from a park or garden, &c. Knight strongly objects to appropriation, and ridicules certain attempts of this sort, made by placing the family arms on the inns and public-houses of the neighborhood, and on "stones with distances," as, he says, was recommended by Addison, fourscore and ten years since. Instead of his idea, or the principle; but as a man with other objects, and we believe, almost every professional man, finds it a very principal object of attention. Repton defines appropriation to be, "that command over the landscape visible from the windows, which denotes it to be private property belonging to the place. A view from a London house into a square or into the parks may be cheerful and beautiful, but wants appropriating; it wants that charm which only belongs to ownership — the exclusive right of enjoyment, with the power of refusing others that should share our pleasure. The most romantic spot, the most picturesque situations, and the most delightful assemblage of nature's choicest materials, will not long engage our interest without some appropriation; something we can call our own; and, if not our own property, at least that may be endeavored to us by calling it our own home." (Fragment of Landscape-Gardening, p. 206.) This envie de s'arrondir seems to have existed, and the proximity and intermixtured of property to have been felt as an evil among landed proprietors from the earliest ages. Ahab desired the field of Naboth, that he might convert it into a garden of herbs (or flower-garden), because it was near to his house; and MarVel, the attorney, says to his patron, —

What course take you
(With your good patience,) to hedge in the manor
Of your neighbor, Master Frugal? As he said,
He will not sell, nor borrow; nor exchange;
And his land lying in the midst of yours,
Is a Maim-bond. Is that a New Way to pay Old Debts, Act 2. Scene 1.

"I stick still in the inn of a hired house," writes the amiable Cowley to Evelyn, "without that pleasantest work of human industry, the improvement of something which we can call our own."

Sect. II. Of the Beauties of Landscape-Gardening, considered as an imitative Art, and of the Principles of their Production.

7176. The chief object of all the imitative arts is the production of natural or universal beauty. Music, poetry, and painting, are the principal imitative arts; to these has been lately added landscape-gardening, an art which has for its object the production of landscapes by combinations of the actual materials of nature, as landscape-painting has for its object their imitation by combinations of colors. Landscape-gardening has been said "to realise whatever the fancy of the painter has imagined" (Girardin); and, "to create a scenery more pure, more harmonious, and more expressive, than any that is to be found in nature herself." (Alison.) Such are Alison's ideas of the powers of this art; and such appear, in some degree, to have been those of Wheatley and Girardin. A more correct idea of its capacities, in our opinion, is suggested by the remark of Lord Wal-
pole, when he represents it as "proud of no other art than that of softening nature's harshness, and copying her graceful touch." It has also been said, that it is "to poetry and painting, what the reality is to the representation." (Girardin.) But experience proves, that the former (the reality) is always exceeded by the latter, both in respect to natural and picturesque beauty. Suppose, for example, any given variety of ground, rocks, and distance, as the basis to be furnished with wood, water, and buildings; the rocks shown, or concealed, as the gardener may wish, or as the genius of the place may require, and every other purpose effected, which is in the power of gardening to perform. When all this is done, it will be a scene greatly inferior in beauty to the imitative creation of a painter from the same groundwork and materials; or, let there be a natural landscape, either of mediocrity or of any given beauty, with every circumstance so arranged, as to be alike suitable for both arts; and let a painter and a gardener, each attempt to copy it according to their art, with or without permission, to improve its beauties. Which of the two imitations would be most beautiful, considered in the abstract, and without reference to any selfish or arbitrary association? Decidedly, in our opinion, the production of the painter. In short, no comparison between the powers of landscape-painting and those of landscape-gardening can be instituted, that will not evince the superior powers of the former art. The great source of the beauty of every verdant landscape is wood; and so much of the beauty of all woods depends on accidental circumstances, in their progress from the time of planting, till they attain a considerable age, and which circumstances cannot be said practically to be under the control of the gardener, that however high our aim, however we may study the natural effects of time, and however correctly we may imitate them, at the end of all our labors, any wood of art will always be far inferior to a wood of nature under the same circumstances. For further illustrations, we have only to appeal to such painters as have made landscape their particular study, and who certainly must be considered in this case as the best judges with regard to scenic truth or picturesque beauty.

7177. To what kind or degree, of beauty then, can landscape-gardening aspire? To this we answer, that, abstracted from all relations of utility and design, it can seldom succeed in producing any thing higher than picturesque beauty, or such a harmonious mixture of forms, colors, lights, and shades, as will be grateful to the sight of men in general; and to such, more particularly, as have made this beauty in some degree their study. This harmonious assemblage of objects may be grateful and agreeable, without being accompanied by any, or at all events, by much general expression; for example, of gaiety, melancholy, grandeur, simplicity, or elegance; but it may also combine one or more of these poetic or general beauties in a high degree, and this, too, with or without being picturesque. It may recall many other pleasurable emotions, if we admit the considerations of fitness, novelty, or its contrast to surrounding scenery, and utility or its adaptation to man. Such is our opinion of the capacities of landscape-gardening. If it is lower than that of some authors and artists, we can only say, that it has been formed from the observation and experience of what actually takes place. The artist may and ought to aim at the highest degree of beauty, which his own imagination, the genius of the place, and the views of the owner, will admit of; but let him not proceed with, or hold out to the world, mistaken views of what his art can and cannot perform.

7178. The principles of imitative landscape-gardening, in that view of this term which limits it to "the art of creating landscapes of picturesque beauty," we consider with Girardin, Price, Knight, and other authors, to be those of painting; and in viewing it as adding to picturesque beauty some other natural expression, as of grandeur, decay, melancholy, &c. we consider it, with Pope, Warton, Gray, and Eustace, as requiring, both in the designer and observer, the aid of poetic mind; that is, of a mind conversant in all these different emotions, or pleasures of imagination, which are called up by certain signs of affecting or interesting qualities, furnished by sounds, motion, buildings, and other objects.

7179. If taking a third view of imitative landscape-gardening, as "the art of laying out the grounds of a country-residence," then, with popular opinion, we comprehend under the term all the above beauties, with those of relative beauty, the principles of which have been the subject of the preceding section. The principles of landscape-gardening then, as an imitative art, we conclude to be derived from nature, as developed by the principles of landscape-painting; and, as recognised by poetic mind, or a mind alive to those general beauties or associations universally felt in civilised society. We consider this, perhaps to many a tedious development of the principles of landscape-gardening, called for by the vague and indefinite manner in which they are spoken of by authors, no less than by artists; and, as a proof of this, we refer our readers to the volumes of the late Repton, who, whatever may be the merits of his practical taste, has certainly, whenever he has touched on the subject of principles, written in a very unsatisfactory manner. To those who are conversant with the literature of landscape-gardening, it must appear a very gratuitous task to write a book "with a view of establishing fixed principles" in the
art, and to find in such a book, after the publication of the works of Wheatley, the two Masons, De Lille, Price, and Knight, such a passage as the following: "If any general principles could be established in this art, I think they might be deduced from the joint considerations of relative fitness or utility, and comparative proportion or scale; the former may be referred to the mind, the latter to the eye." (Obs. on L. Gardening by H. Repton, Esq., Introduction, p. 2) While we disapprove of this disingenuous mode of writing, the frequency of which we must regret in this artist's works, we willingly pay tribute to his practical good taste, and more especially in architecture.

7180. As an illustration of the theory of landscape-gardening, which we have adopted, we subjoin a slight analysis of the principles of a composition, expressive of picturesque and natural beauty. For this purpose, it is a matter of indifference, as far as respects picturesque beauty, whether we choose a real or painted landscape; but, as we mean also to investigate its poetic or general beauty, we shall prefer a reality. We choose then a perfect flat, varied by wood, say elms, with a piece of water, and a high wall, forming the angle of a ruined building; it is animated by cows and sheep; its expression is that of melancholy grandeur; and, independently of this beauty, it is picturesque in expression; that is, if painted it would form a tolerable picture.

7181. Unity is the first obvious principle which pervades this picture. No ideas of gaiety or prettiness are excited by such a scene. All the parts unite in forming a whole, which the eye can comprehend at once, and examine without distraction. "La vue," says Girardin, "le plus vagabond de tous les sens, a besoin d'un ordre forcé pour former un concept. While the eye with its vision is limited to the surface of objects, the lake, the building, would only please when considered separately, and the result would be as poor a production as a machine, the wheels of which are accurately, finished and nicely polished, but which do not act in concert so as to effect the intended movement.

7182. True to nature; that is, the materials or materials which appear to be. The trees, which are neither very old nor very young, though in the distance diminished by their remote situation, we discover by their trunks and contour, to be still trees. They are not shrub placed near the eye, with a view to produce a false perspective; nor is the fragment of building merely a disguised wall, because it has opening which have once been windows, and is crowned in one part by battlements. The water is truly natural, its surface being below the level of the adjoining ground, not raised above it, as is often the case in artificial waters. This completes the truth or reality of the scene. The necessity of adhering to truth is still greater in a picture in which all objects are meant to be natural, not only in form and size, but also relative to the forms and colors around them. Objects, especially those whose forms and dimensions are familiar to us, as men or horses, painted of different heights in the same plane; as, for example, in the distance, of the same magnitude as that in which they appear in the foreground, would, from the acquired habit of measuring a man or an animal, twist the eye and appear as false objects, or species, or monsters. It seems to be from the same principles of being true to nature, that a gradation of scene, or what is called distance, is required, or at least is so satisfactory in landscape. The mind, after being impressed with the effect of a whole, delights in examining its parts in succession; the more simple and less important, first; after that, the more consequent of the whole, and therefore the more does the mind acquiesce in its effect. The eye of the artist, seizing on the nearest and most remote parts of a scene, readily marks an intermediate or middle distance; no given extent seems necessary for this purpose:

"To make the landscape grateful to the sight, Three points of distance always should unite; And howsoever the view may be confined, Three marked divisions we shall always find."  

The Landscape, by Knight.

7183. The disposition of the parts is the next object of analysis, and the enquiry is how in this respect they concur in forming a whole. As to forms, we find that their disposition is in groups or masses. The picture contains one side of a hill, which projects in the foreground towards the opposite side of the middle distance, including the building and adjoining lake; and, the remote, or third distance, consists of a low line of wood, with projecting groups or masses. As to colors, we find only different shades of yellow and green on the trees and ground. As to the light, we find one large and principal light nearer the water, as it approaches the side; the other, the most distant part is the water, and the next closest the building, and the third light spreads over a broad space of ground, near the water. The groups in the foreground are all in a deep shadow. One of these, near the water, projects of the principal light, and in the third distance are distinguished by a sort of neutralisation of light, color, and shade. Such is the disposition of the groups or parts, in order to form a complex view of the whole, to fix the eye, and prevent it from being distracted by scattered lights, confusion of forms, and inharmonious color.

7184. The connection which subsists between these different parts is a subordinate but important consideration. 1. They are connected in each distance by a real nearness of situation; and, 2. In the view as a whole, from the one group coming in part before the other, so as to produce connection by apparent proximity. Suppose the reverse to be the case, and that the groups were unconnected either by real or apparent connection, the building would become a distinct object. The eye would have no resting place, and the assemblage would not compose a whole.

7185. The relation which subsists between the parts, composing each individual group, is next to be examined. 1. In regard to the form of the parts of each group, as they are all groups of the same sort of tree, we find one elementary form prevalent, but differing in magnitude, and in combination, by their contrasted disposition, to such a degree, that each group differs in form from the others, without at the same time being of opposite forms.

7186. In regard to color, the same kind of color prevails in each and in all of the groups, but is varied in degree by the same contrasted disposition. In some parts a yellowish-green prevails, in others a russet or red-green, and occasionally a bright green, as on that part of the turf where the light is less with the greatest brilliancy.

7187. In regard to light and shade, those parts of the groups which rise above the horizon, and are backed by the sky, are dark, and generally darker than such as are backed by the ground, or by other adjoining groups; the latter being more regular than the former, and in the extreme shadows, more dense than the intervening lights. These prominent and retiring parts, in the near groups, are very numerous; in the distance they are lost in the general aerial shade of the group. It may be observed, as a general principle, that trees, from their rough surface, and consequent imperfect reflection of light, are always comparatively darker and more shaded than other objects. In creating a real landscape, they serve in some measure as shades, as the other materials mentioned serve as lights.

7188. The sky, the cows, and the sheep, must be noticed in order to complete the sketch. Suppose, then, that the sky is merely grey and cloudy, and the cattle and sheep grouped in the middle distance,
what will be the expression of the view? We think it would express very little to general observers; but there being nothing glaringly offensive in the arrangement, it would be expressive of some beauty to him who had bestowed some attention to the subject of landscapes; for though it exhibits but little harmony of forms and colors, light or shade, it still possesses enough of these ingredients to render it worth looking at as a picturesque view.

7189. The general or natural expression of melancholy and grandeur remains to be accounted for. For this purpose, let the building be the ruins of an ancient castle, whose lofty quadrangular form may be readily imagined from the walls we mentioned, as composing a part of the scenery. The character of grandeur, then, is not in this instance communicated to the picture, by the picturesque effect of the walls, which have no variety of form, light, or shade, in themselves, but by the mental associations to which they give rise in a cultivated mind.

7190. As another example of picturesque, and poetical, or sentimental expression, imagine the cattle and sheep removed, the surface of the ground covered by smoothly mown turf, and the luxuriant branches of some of the foreground trees nearly reclining on the ground. The first expression would be that of beautiful, or elegant picturesque; the next that of stillness, and consecration to man,—stillness, as being without animals or moving objects; and consecration to man, from the mown surface, greatly heightened by the circumstance of the branches of trees reclining on the ground, which never can happen where sheep or cattle are admitted, and which forms the leading visible distinction between a group of trees in a park, and a group on a mown lawn. It is not from the smoothness of the turf, or any particular mixture of light and shade in the reclining branches, that this expression is produced, but from reflecting on the cause of this appearance.

7191. As a third example, imagine, instead of the smooth turf, an uncouth rough ground, covered in some places with furze, briars, brambles, and tangled thickets; the water fringed with rushes, and partially concealed by aquatic shrubs; and wild horses and deer forming the animated part of the scene. The expression would be eminently picturesque; but there would also be an expression of wildness, not resulting from the picturesque qualities as such, but from mental reflection on the difference between this scene and one of cultivation.

7192. As a fourth example, imagine the view deprived of the lake and the building, and consisting only of the wood and ground, with the heads of a straggling row of willow-trees appearing in the middle distance, and the sound of a distant waterfall heard through the trees. Here, to picturesque beauty we have an idea of water—of an immense body of it in the lake or river which supplies the waterfall—and of the rocks, which compose their powerful obstruction to a body of water. The reader will here remark, how much of the sublime beauty of this scene depends on sound, which can never be included under picturesque beauty. The leading expression is that of sublimity, accompanied by various associations of dignity produced by the rocks, and of grandeur suggested by the stream, after the waters have reviewed their tranquil course, and rolling, as we may imagine, majestically along under the shade of the line of willow-trees.

7193. Other examples, of a more striking nature, might be adduced; but these instances we consider as better adapted to show the difference between a composition merely picturesque, and one expressive of general or natural beauty, and to prove our position, that both poetry and painting enter into the principles of imitative landscape-gardening. They will also show, how very little the production of natural beauty is within the power of the landscape-gardener. He may display it to more advantage. In the first example of expression, for instance, the building, or such parts of it as more obviously show its real character, might be displayed by the removal of some over-obtruding branches; and in the second, a garden-seat, and some garden-trees, as the lime, cedar, &c. might add to the idea of consecration to man. In the third, a corn-field or a barn in the distance, would aid the effect by contrast; and in the last, a bridge would determine the situation and reality of the river. But to attempt effecting these expressions by building a ruin, placing a garden-seat in a paddock, or erecting a bridge where there was no water, would, however common in the infancy of the art, be now justly considered ridiculous. Much more, it is true, might be done in improving the picturesque beauty of each of these scenes, provided the trees were already grown to maturity, and too numerous rather than too few; but if the trees are yet to plant, it is evident that only the ground-plans of the masses and groups of trees, and of the breadth of the lawn, could be formed by the artist.

7194. A very common error, since the introduction of the modern style, has been to suppose that picturesque beauty is the only beauty to be aimed at in laying out grounds; but so far from this being the case, it will often happen that the alterations required for
the purposes of convenience and character, will lessen that beauty, whilst it increases that of dignity, refinement, and appropriation to man. As an example, we may refer to Rivenhall Place, in its state before being improved by Repton (fig. 681.), and the

same residence subsequently to improvement, or as intended to be improved. (fig. 682.) Every one will allow that its unimproved state (fig. 681.) presents the most picturesque landscape; while its dressed state is the more dignified and desirable as the landscape of a considerable country-residence.

Chap. II.

Of the Materials of Landscape-Gardening.

7195. The materials of landscape-gardening with which we work in order to obtain the desired effect, are the same whatever style we adopt. Those of nature, are ground, wood, water, and rocks; to these, art has added buildings, roads, walks, fences; and animated or moving objects, sounds, &c. may be considered as accompaniments only partially under our control.

Sect. I. Of operating on Ground.

7196. The operations of art on this ponderous material are necessarily of a very limited description. The most extensive and costly operations, to restore or create natural surfaces, even when attended with the desired effect, afford less permanent gratification to personal feeling than most other improvements. If a deformed space has been restored to natural beauty, we are delighted with the effect, whilst we recollect the difference between the present and the former surface; but when this is forgotten, though the beauty remains, the credit for having produced it is lost. In this respect, the operations on ground under the ancient style, have a great and striking advantage; for an absolute perfection is to be attained in the formation of geometrical forms, and the beauty created is so entirely artificial (fig. 683.) as never to admit a doubt of its origin. Long, therefore, after the improvement is finished, the credit and the beauty remain to gratify and charm the owner. Improvements on surfaces, whatever be their object, ought to be made in scenes which are near the eye, or intended to be frequently seen; at a distance they are lost if the effect be on a small scale, and often better effected by wood, if on one of considerable magnitude. Attempts to remove distant inequalities, by lowering heights and
filling up hollows, very seldom are attended by results sufficient to justify the expense incurred; but when art is employed to heighten distant eminences the success is greater: in the last case art may be said to act positively, in the former negatively—to produce or increase a beauty, instead of only removing or lessening a deformity. All operations on ground may be included under, 1. Those which have for their object the beauty of art or design; and, 2. Those where natural beauty is intended to be produced.

7197. Operations with a view to relative or artificial beauty. The forms in use for this purpose are few and simple. They originate in, and are influenced by, those of the house; and are, for the greater part, bounded by right lines; and the surfaces are levels or slopes of different degrees of abruptness. The magnitude as well as form of each of the figures in the ground immediately adjoining a house, or in a detached walled enclosure, should be regulated chiefly by the magnitude of the mansion, or extent and grandeur of the whole place, though they are often obliged to conform, in some degree, to the natural surface. When the ground slopes from the house in all directions, narrow parallelograms will be the prevailing forms both of the levels and slopes. The broadest level, and greatest perpendicular depth of slope, will generally be placed next the house, and the next broadest level, &c. in succession, till, after three or four levels, and as many slopes are obtained, the artificial surface shall finally blend with the natural; unless, as is frequently the case in the geometric style, a kitchen-garden wall, or some similar work of art, forms the termination. In this case, separation by some architectural or other accompaniment, will, by forming a break in the order of forms, admit of adopting, in continuation of the artificial surface, such levels and slopes as the character of the scene may require, or a due regard to economy dictate. When the mansion, or scene of operations, is on a surface naturally flat, the levels will be of greater dimensions, the slopes smaller, and both fewer in number. But though parallelograms are the common figures employed, sections of polygons, trapeziums, circles, and curvilinear figures, are frequently admitted. They are used in architectural elevations, and in fortifications, which are the prototypes of this part of ancient gardening; and, therefore, when apparent in the mansion, should be reflected, as it were, by the grounds. (fig. 684.) The forms to be used, however, is a matter easy to determine. The principal difficulty is to arrange them together, so that they may concur in producing a whole, or a good effect. In disposing, connecting, relating, and contrasting them for this purpose, the artist will preserve regularity and uniformity in the complex view of the whole, varying and harmonising the detail according to the degree of beauty and variety he intends to produce. If he has duly prepared his mind by theoretical studies, and practised architectural and landscape drawing, his own feeling of their impression will suggest when he has attained the desired effect; for the models of artificial surfaces which remain of ancient gardens are poor productions compared to what might be created in this way, through the judicious application of the principles of relative beauty. A good deal depends on adjusting the extent of geometrical or architectural surface to the size of the house and surrounding grounds; and in this matter much depends on the regularity or irregularity of the ground plan of the former, and on the evenness or variation of the surface of the latter. A square house on a level, or on a gentle swell, will require least extent of architectural platform around it, and a straggling gothic castle on an irregular declivity the greatest extent of terraces, angles, ramps, and slopes.

7198. Natural beauty of ground. As the right lines and geometrical forms of the architect, take the lead in grounds of artificial beauty, so the flowing and broken lines, and undefined forms of the landscape-painter, take the lead in those of natural beauty. To create them in ground, is generally impracticable and unadvisable; but where they exist concealed by accidental deformities, or incomplete in expression, through dulness in their leading features, art may relieve from the impediments to beauty, even though the situation is at some distance from the eye. In recluse scenes immediately under view, art may aspire to create beauty even from a tame flat, but especially from its opposite, a flat abounding with deformities. In effecting all those purposes, the same principles apply. The first thing to fix in the mind is the desired surface, or that style of natural ground which is best to be imitated. The next thing is to examine on what parts, forms, and lines, the natural beauty of this ground chiefly depends; if undulating, whether the concave or the convex prevails; if broken ground, whether horizontal and perpendicular, or curved and inclined lines prevail. These are then to be imitated in the improvement, ever keeping in view the important principle of a whole as the end of the connection, and harmony of the parts of which it is composed.
7199. The removal of accidental deformities forms one of the commonest operations on ground. Old quarries and other pits, useless cattle-ponds, open drains, mounds of earth, marks of ridges, are to be considered of this description. As they have been raised by art, so in dispersing them, the best general rule is to restore the natural surface; but sometimes the remains of fences are so numerous, that advantage may be taken of the earth to be removed, and some variety given to a surface otherwise dull and featureless. If the fence consists of a great number of turns of different lengths, by removing both the mound and part of the surface on each side of the drain, a small winding hollow or vale may be formed: the effect of which may be heightened, by placing the earth removed on adjoining indications of natural eminences; not so as to form knolls, but so as to connect and harmonise with the prevailing idea of expression. The most simple and obvious improvement of exhausted quarries and dry pits, is to plant them (fig. 685.); this, though it will form a series of pleasing scenes, is not always consistent with the general expression to be created, and such groups as would arise from these spots, might destroy breadth of light and connection, independently of excluding distant objects. In this case, they must be filled up by under-growths, or by lowering the adjoining surface in such a way as not to interfere with general effect, or a sufficient descent for the surface water. Where broken ground enters into the idea of the composition to be effected, open drains, or hollow pits, afford fine sources of picturesque beauty, especially if the ground is dry, or can be readily under-drained. This character, however, can seldom be introduced as an original feature; but in ground naturally leading to abrupt and broken lines, it may be more desirable to improve this expression, than attempt creating a more polished surface. In cases of this sort, almost every thing depends on the introduction of wood, copse, and verdant roughnesses, to harmonise the broken surface; for mere broken ground, without a character of luxuriance and wildness communicated by wood, is seldom better on a smaller scale than a surface deformed by scars.

7200. Natural bumps or excrescences (fig. 686. a), as well as pits (b), are not uncommon in many grounds which have not been subjected to agricultural improvement.

When these are not large, the process of fallowing with the plough will remove them; when they are of some magnitude, they may often become sources both of polished and picturesque beauty. If they are numerous and favorably distributed, by the removal of some, and the enlargement through that means of others, they may give an impression of undulation, especially if situated on a naturally irregular surface. If on a declivity, and covering rocks or huge stones, a mixture of flowing lines with abruptnesses may be happily introduced.

7201. A varied but yet dull surface may often be improved by a skilful artist. By studying the character indicated by nature, it will generally be found, that the deficiency of expression is owing to the hollows being in part clogged up, either naturally or by long continuation under the plough; and the swells lowered in a corresponding degree by the same process. In this case, the obvious improvement is to remove earth from the hollows, and place it on the eminences, ever keeping in view the natural expression, and avoiding to end the improvement, by leaving the hollows gutters, and the eminences pointed ridges. This sort of improvement is not a very obvious one, though often attended with surprising effects, for every foot of depth taken from a hollow, and laid on an adjoining hill, adds two feet to the height of the latter. All these observations will be understood as referring to grounds near the house.

7202. Distant scenes of a park, as hills, or mountains (fig. 687.), are only to be improved by wood; and these remarks, in so far as they extend, will suggest not what is to be removed, but what must be concealed. Many excellent hints on this part of the subject are to be found in the picturesque tours of Gilpin, referring to ranges of
hilly scenery in different parts of the country, of much of which he has given views. With respect to ground, as respects garden-scenery, almost the only writer who has treated of it at length is Wheatley, whose excellent book, so frequently referred to by all succeeding writers on gardening, ought to be in the hands of every man of taste. In the chapter on ground in that work, the author concludes with a salutary caution, which ought ever be taken in connection with the wisest rules; "a caution which has more than once been alluded to, must always be had in remembrance; never to suffer general considerations to interfere in extraordinary great effects, which rise superior to all regulations, and perhaps owe part of their force to their deviation from them. Singularity causes at least surprise, and surprise is allied to astonishment. These effects are not, however, attached merely to objects of enormous size; they frequently are produced by a greatness of style and character, within such an extent as ordinary labor may modify, and the compass of a garden include. The caution, therefore, may not be useless within these narrow bounds; but nature proceeds still farther, beyond the utmost verge to which art can follow, and, in scenes licentiously wild, not content with contrast, forces even contradictions to unite. The grotesque, discordant shapes which are often there confusedly tumbled together, might sufficiently justify the remark. But the caprice does not stop here; to mix with such shapes a form perfectly regular, is still more extravagant; and yet the effect is sometimes so wonderful, that we cannot wish the extravagance corrected." (Obs. on Mod. Gard. p. 23.)

Sect. II. Of operating with Wood.

7203. Wood produces almost all the grand effects in both styles of improvement; for trees, whether in scattered forests, thickets, or groups, or in compact geometric squares, avenues, or rows, constitute the greatest charm of every country. Trees improve the most varied outlines of buildings (fig. 688.), and without them the grounds

of a residence (fig. 689.) would often be nothing more than an unmeaning profusion of winding roads or walks. A tree in itself is, indeed, the noblest object of inanimate nature; combines every species of beauty, from its sublime effect as a whole, to the individual beauty of its leaves; exhibits that majestic uniformity and infinite variety which constitute the essence of relative beauty; and the natural expressions of individual species are as various as are their forms and magnitude, their utility to man, and the situations, soils, climates, and other general and accidental circumstances of which they are indications.

7204. The effect or expression of trees, individually and in masses, has been entered on at length in the preceding book; we shall here, therefore, confine ourselves to a few general observations on the effect of planting in the geometric and modern manners.

7205. In planting in the geometric style, the first consideration is the nature of the whole or general design; and here, as in the ground, geometric forms will still prevail, and while the masses reflect forms from the house, or represent squares,
triangles, or trapeziums, the more minute parts, characterised by lines rather than forms, such as avenues, rows, clumps, and stars, &c. are contained in parallelograms, squares, or circles. In regard to the parts, masses and avenues should extend from the house in all directions, so far as to diffuse around the character of design; and as much farther in particular directions as the nature of the surface admits of, the distant beauties suggest, and the character of the mansion requires. In disposing these masses, whether on a flat or irregular surface, regard will be had to leave uncovered such a quantity of lawn or turf as shall, at all events, admit a free circulation of air, give breadth of light, and display the form of the large masses of wood. Uniformity and variety as a whole, and use as well as beauty in the parts, must be kept constantly in view. Avenues, alleys, and vistas, should serve as much as possible as roads, walks, lines of fences, or screens of shelter or shade; but where this is not the case, they should point to some distant beauties, or near artificial objects, to be seen at or beyond their termination. The outer extremities of artificial plantations may either join natural woods, other artificial scenes, cultivated lands, or barren heaths or commons.

7206. When artificial plantations join natural woods, the avenues, alleys, and circular glades of the former may be continued a certain length in the latter, so that the point where the natural wood begins, and the artificial plantation ends, may not be discoverable. In aid of this effect, the sort of tree which prevails in the natural scenes, should also prevail in the adjoining parts of the artificial wood. When artificial scenes join other artificial scenes, nothing can be easier than by the reciprocal continuation of avenues, strips, or masses, so far to unite the two seats, as to conceal the boundaries of each, while the two mansions will thus each borrow a splendor from the other. There are still existing proofs of the attention paid to this subject in former times, an instance of which occurs in the apparent connection by avenues between Blenheim, Ditchley, and Heythrop, though the last mansion is nearly ten miles distant from the first.

7207. When artificial scenes join cultivated lands, if those lands are enclosed, broad strips, hedge-rows, square or round clumps in the angles of the fields, with such reciprocal disposition of lines or forms as the case may suggest, will continue the character of artificial plantation; and where roads are necessary, if utility does not forbid, they should be formed in part as avenues, in continuation of those within the artificial scene.

7208. When artificial plantations are bounded by barren heaths or commons, all that can be done is to advance beyond the boundary of the place portions of avenues, and rows of trees of different lengths. Sometimes an inequality, crowned by a clump or thicket,
may promote the idea. On other occasions, where the heath or waste may be so bleak as to convey no agreeable expression, and therefore is, of course, struck out entirely from the improved scene, a sort of connection may be given, by advancing strips or rows from the boundary plantation into the heath. Even single or scattered trees, if they can be protected in that situation, will have a tendency to produce that sort of connection required; and, while it gratifies the proprietor's love of appropriation, will please the eye of the traveller, who views the country as a whole, and delights to observe the harmony and beauty of its principal features. Having disposed of the whole, and of the parts, as far as respects their general effect and connection, what remains to be considered is, the sort of tree, manner of disposing the plants, fences, and future management.

7209. When the object in view is the expression of art and design, the propriety of employing species of trees different from those which are natural to, or most abound in the surrounding country, is obvious. In a country of common pine, the spruce and silver firs and cedar afford a choice. In a country of oaks or elms, chestnuts, limes, and planes, form suitable contrasts. Where the plantations are extensive, the value of the timber must always be a principal object; and, therefore, the contrasted trees should be chosen accordingly. Some species, however, are so happily adapted for this style, and as ornamental trees in both styles, that they ought seldom to be omitted excepting near the house: such for example, as the horse-chestnut, lime, Spanish-chestnut, plane, lucombe oak, cedar, stone pine, &c. As the four last species mentioned are, in exposed situations, liable to injury from extraordinary severe winters, a few hardier sorts, resembling them in general appearance, should be intermingled in the plantation, to preserve the larger masses in case of accident, but to conform with the general effect in color and style of foliage, as well as in form. Different species ought not in general to be mixed together in the masses; one, or at most two, conforming varieties are sufficient; more would destroy the breadth of color of the mass, and the character of its surface. Different masses, avenues, and more minute parts, may, however, be planted with different species of trees; rare sorts may be also introduced in lines, along the front of many of the masses, ranged along stars, crosses, &c. The snowdrop-tree, from its beautiful blossoms, and the birch and hazel, for the display of their catkins during winter, are well calculated for walks adapted to that season of the year, and should be planted in front of pines, or other evergreens. Such also is the principal situation for flowering shrubs, and no plants can be more showy than the horse-chestnut, common lilac, acacia, guelder-rose, Portugal laurel, holly, bird-cherry, pyrus, mespilus, and laburnum, in similar situations, and for general purposes. In distributing the species of tree in extensive masses, the same general principles of composition must be attended to, which we have pointed out, as far as respects form. The colors and character of the heads of the trees must be connected, and, at the same time, to a certain degree contrasted, in order to produce an artificial and yet harmonious effect.

7210. Whether the new varieties of American and other trees, obtained since the introduction of landscape-gardening, are to be admitted under this style of improvement may be questioned by some. We answer, certainly, unless where the object is the imitation of an ancient residence (fig. 690); and there can be no doubt that where such is the object, exotic trees will destroy part of the allusion; but we do not contend for the revival of the ancient style solely as producing imitations and allusive characters, or on account of its antiquity, but as a distinct mode of gardening. We would therefore not copy its faults or study its defects, but add to its beauties from all the resources furnished by the present improved state of the arts of design, as well as by the continued accession to our stock of trees and shrubs. If however a positive imitation of an ancient residence is intended, then the species of tree should be limited to those used in ancient times, as well as the forms and lines of their disposition.

7211. The manner of disposing the plants is influenced by the same principle of avowed
art; in rows, equidistant masses, in squares, or in quinconx, and in every case so as never to be mistaken for trees or shrubs sprung up accidentally.

7212. *Fences.* Here the ancient style has a grand advantage over the modern, in which, as far as respects the imitation of nature, all fences are to be considered as temporary, and, therefore, to a certain degree, looked on as nuisances to be afterwards removed. Besides, their irregular and circuitous line is displeasing to many who do not understand ground-plans, with a view to picturesque beauty, when the trees are grown up. But in geometric gardening, fences are to be considered in many cases as objects, and when not regarded in this light, their directions and limits are so minutely pointed out by the determined outline of the plantations, that the eye acquiesces in their situation and use. Fences of any common and economical description are employed to protect the trees of open avenues, open groves, and single open rows. But the more common kind are walls, which in the prominent parts ought to be well built of shaped stone, and substantially finished by raised or flat copings, bearing some relation to the copings of the simpler parapets of the house. The gates necessary in these walls, as well as in some sorts of permanent verdant fences, supply occasion for such architectural forms and lines, as are advantageous in reflecting those of the mansion, and strengthening the prevailing idea of dignity, art, and design. Every sort of fence belonging to the modern style, may be occasionally employed in the ancient; and besides walls, half-sunk walls, and raised mounds with a walk at top, we may enumerate hedges of holly, yew, laurel, and other shrubs, either simple or chequered, by alternate deciduous or evergreen species, varied by arcades and standards, shorn into shapes, or in their natural growth. Hedges of flowering shrubs may also be introduced; of creepers on open palisades; and various others of great beauty may be invented, or are to be found in books on this style of gardening.

7213. *Management.* In this respect also, the advantage is greatly in favor of the ancient style; for as all operations of pruning and thinning in the other should be done under the eye of the landscape-gardener, so all these operations here may be performed by any laborer; the object being simply to produce a straight, upright, smooth stem, to a certain height according to circumstances, and allow each particular tree to attain its full size. Shearing or clipping is always a mere mechanical operation; plain hedges and close alleys require only a line for a guide; and in the case of arcades or verdant sculpture, there is, or always should be, a frame of trellis-work of correct design to guide the operator. From the comparative brevity of this view which we have taken of planting under the ancient style, the reader will perceive, that we are far from supposing it to take the lead of the natural method to which we now proceed, referring for more particular information to Le Blond, and other French authors; and to Switzer’s *Ichnographia Rustica.*

7214. *In planting with a view to natural beauty,* the effect of the whole is here also the first and the grand consideration. Country-residence, must necessarily be materially influenced by the character and situation of the house, as the capital feature in the composition. To this feature, the leading masses of wood and lawn, answering the end of light and shade in painting, must invite and direct the eye in the general view of the place. (fig. 691.) Each must embrace it on one or on more sides, and diverge from it in masses suitable to its magnitude and the extent of the grounds, and in forms and characters of woody surface, suitable to the natural situation and the expression to be created. If the mansion is on a declivity, the principal light should embrace the front which looks down, rather than those which look up, or on either side. The views from the windows suggest this arrangement, and will point out in every other situation, whether a flat, a hill, or an irregular surface, on which side or sides the leading masses are to have their origin. To determine their magnitude, form, and number, would be impossible, without
a particular case to refer to. To point out their style is sufficient, which must always be irregular like nature; generally stretch along such rising ground as the situation affords; and, like her, always combine a certain degree of uniformity or recognisable shape, even amidst the greatest seeming deviations from this quality of figures. As the house indicates the commencement of the masses, the character of country surrounding the scene of improvement must determine the limits and style of their termination. If the lands are laid out in regular enclosures, bounded by hedges and hedge-rows, fragments of these (fig. 692.) must prevail in the margin of the park; at least in as many places, and to such a degree, as will produce connection; and, if possible, as much farther as will harmonise the scene within, with the country without. If it is entirely or in part surrounded by forest scenery, the termination is easily and completely effected, by attending to the style of wood and species of tree prevailing without, for a moderate distance within the boundary. If bounded by the sea, or a large lake, an abrupt termination will be as natural as it would be formal on the margin of a cultivated surface. Abrupt terminations, however, are often unavoidable, as in examples of villas, where the owner having no demesne, has no control beyond his boundary fence. All that can be done, therefore, in such cases, is, to create as much beauty and interest as possible within the given limits. Where one villa joins another, this sort of isolated abruptness is avoided or lessened; and, in the case of suburban villas (fig. 693.), it is seldom felt as any deformity, though, even here, connection and general harmony with what is exterior, will add beauty to what is within.

7215. The details of planting in this style have already been given at length in the preceding book.

Sect. III. Of operating with Water.

7216. Water is a material of so captivating and interesting a description in the different characters in which it occurs in nature, that no view can be reckoned complete in which it does not compose a feature. It forms a part of every garden in the ancient style, in the various artificial characters which it there assumes of oblong canals, ponds, basins, cascades, and jeux-d'eau (fig. 694.); and in modern improvement, such is the
value attached to its effect, that no place is deemed perfect without a river or lake; and such the indiscriminate desire of obtaining them, that nature has been too frequently disregard ed in their form and situation. Of the characters which water assumed under the geometric style, we can only observe, that their names convey, in a great degree, an idea of the forms. Their situations were near the mansion; and their marginal accom paniments of masonry, turf walks, and hedges, were determined by the architectural forms and lines of the capital feature in the scene. The choice, from the most intricate and curious fountains to the plain oblong canal, depended on the splendor of the general design; very little on natural situation. The supply was generally obtained from some concealed reservoir.

7217. To imitate lakes, rivers, or rills, and their accompaniments, is the object of landscape-gardening; and of each of these natural characters we shall remark the leading circumstances in the originals and the imitations. All water is either running or stagnant. Lakes, ponds, and pools, are of the latter class; rivers, rivulets, and rills, of the former description. In certain situations, lakes may be created where their supply is moderate; rivers and rills only when it is abundant. Both characters, when they exist in nature, may be improved by studying the natural characteristics of each species.

7218. Situation, relatively to the character of the ground's surface, is the first consideration respecting water, in whatever form it may appear. No situation in which this material may be supposed to exist and expand itself into a body, can be truly natural, that is not a vale, plain, or hollow. Mountain streams are out of the question; and small lakes or pools, in hollows or elevated grounds, are more to be considered as accidental than as general nature. Even artificial lakes or rivers on a considerable scale, to be natural must either be, or seem to be, situated in the lowest part of the landscape then under the eye. If otherwise, if placed on the side of a declivity over which the eye can range at the same time, it may be attractive to a stranger at first view; but the want of truth or fidelity to the thing to be imitated, will soon bring on an increasing aversion in the mind of genuine taste.

7219. Ponds in different levels, seen in the same view, are very objectionable on this principle. The little beauty they display as spots, ill compensates for the want of propriety; and the leading idea which they suggest, is a question between their present situation and their non-existence. The choice, therefore, as to the situation of water, must ever depend more on natural circumstances than proximity to the mansion. Is then all water to be excluded that is not in the lower grounds? We have no hesitation in answering this question in the affirmative, so far as respects the principal views, and when a lower level than that in which the water is proposed to be placed is seen in the same view. But in respect to recluse scenes, which Addison compares to episodes to the general design, we would admit, and even copy the ponds on the sides or even tops of hills, which may be designated accidental beauties of nature. In confined spots they are often a very great ornament (fig. 695); as a proof of which, we have only to observe some of the suburban villas round the metropolis, where a small piece of water often comes in between the house and the public road with the happiest effect.

7220. A beautiful lake, or part of a circuitous body of water, considered as a whole, will be found to exhibit a form, characterised by breadth rather than length; by that degree of regularity in its outline as a whole, which confers that, which, in common language, is called shape; and by that irregularity in the parts of this outline, which produces variety and intricacy. Supposing the situation to be fixed on for the imitation of a lake (fig. 696.), the artist is to consider the broadest and most circuitous hollow as his principal mass or breadth of water, and which he will extend or diminish according to the extent of aquatic views the place may require. From this he
may continue a chain of connected masses of water, or lakes of different magnitudes and shapes, in part suggested by the character of the ground, in part by the facilities of planting near them, and in part by his own views of propriety and beauty. The outline of the plan of the lake is to be varied by the contrasted position of bays, inlets, and smaller indentations, on the same principles which we suggested for varying a mass of wood. To the irregularity of outlines so produced, islands and 697 (fig. 697.) may be added on the same principle, and for the same objects as thicket and groups. This will complete the character and beauty of the plan of the water.

7221. But the grand effect of water in landscape, depends on wood as its accompaniment. The variety and intricacy of outline, the reflection of forms and colors, the shady recesses and flickering lines of light, all depend on trees. These are not to be sparingly or indiscriminately scattered around the margin, but liberally in some places, for the sake of a contrasted mass of grateful color or shade, to relieve the brilliancy of the water; and with discrimination everywhere to mark the beauties, and heighten the variety of the outline, without destroying breadth of effect, or a whole, either as respects the water alone, or the entire residence.

7222. The marginal banks of water in nature, are tame or bold, gravelly or sedgy, stony or rocky, according to the character of the surrounding ground. Art, therefore, must imitate each in its proper place, not always by a studious picturesque arrangement of the marginal accompaniments in each case, but by excavating the ground-work, planting the trees and shrubs, and leaving the rest to the motion of the waves of the water. After the effects of one winter, stones or gravel may be deposited in spots suitable for stony or gravelly shores. But to enter into this, and many other circumstances in the imitation of lakes, would exceed the proper limits. We add two cautions: the first is, in all cases of the beautiful picturesque, so to arrange by puddling and under-draining, that a marshy appearance may not surround the lake; and that rushes, and such aquatic plants, may not extend farther than a few feet or yards from the margin of the water. The other respects islands, which are the greatest ornaments to lakes. But that island which is placed in the centre, or in any situation where it does not connect with other islands, or with the shore, so as to form part of a prominence or recess, is injurious to the effect of the whole inversely as its beauty, when properly placed.

7223. Rivers and rills, we have said, are rather to be improved than created; for we cannot sympathise with that taste which directs the mimicry of so noble a character as a river, or is satisfied with a nearly stagnated rill. We do not consider the river at Blenheim as an exception, because that piece of water was formed by widening a considerable brook. We allude to those wavy serpentine canals, which are never mistaken for natural scenes, and, in almost every case, might be advantageously exchanged for a lake. A rill, however, may have its course rendered more varied, may be expanded at proper places into regular shapes, and all the alterations accounted for and harmonised by planting. (fig. 698.)

7224. Progress and impetuosity are the two leading ideas which belong to running waters. The first expression may be heightened by counteracting any tendency to expansion; by removing some of the circuitous and oblong projections of earth or stone in the banks; and sometimes by deepening its bed, or by substituting a more direct line for a circuitous course. The idea of impetuosity is indicated by its effects, in reverberating against high banks, or common banks, on which trees are situated, and may be increased by augmenting the cause or the effect, and thus either digging and undermining the trees, cutting down the high banks on which the water acts, or placing very slight piers as jetties on the opposite shore. Picturesque additions to the marginal accompaniments both of
rivers and rills will readily suggest themselves. Cascades and waterfalls may sometimes be created; and the occasional expansion of natural brooks into pools, affords a fine hint for imitation, when this form of water comes within a scene of improvement. One of the greatest improvements that can be made in many places laid out in Brown's time, and subsequently, consists in widening in some places, and varying the margin in others, of those tame serpentining canals, then so much in fashion. By this means, and by adding islands and trees, they may often, without deranging the place as to other details, be rendered highly beautiful at a moderate expense. (fig. 699.)

A waterfall, or cascade, is an obvious improvement where a running stream passes through a demesne (fig. 700.), and is to be formed by first constructing a bank of masonry, presenting an inclined plane (a) to the current, and rendering it impervious to water by puddling(1720.) or the use of proper cements, and next varying the ridge (b) and under side (c), with fragments of rock, so chosen and placed, as not to present a character foreign to what nature may be supposed to have produced there. The adjoining ground generally requires to be raised at such scenes, but may generally be harmonised by plantation.

Where running water is conducted in forms belonging to the geometric style of gardening, waterfalls and cascades are constructed in the form of crescents, flights of steps, or wavy slopes; all which have excellent effects of their kind when appropriately introduced, as at Chatsworth, Hatton, and many other places.

A natural stream may sometimes be improved by altering its direction, and bringing it through a more interesting part of the grounds; and we have known an admirable effect produced by bringing a distant river close to the house, even so much so as to wash the base of its terrace-wall. (fig. 701.)
Sect. IV. Rocks.

7228. The imitation of rocks forms no part of the geometric style of gardening, and are a material of the natural style, equally unsuitable to be created. But though rocks cannot readily be imitated, their expression may sometimes be heightened when desirable, and concealed when disagreeable.

7229. The character of rocks may be savage, terrific, sublime, picturesque, or fantastic. By attending to the forms of the milder characters, and their connection with ground and trees, we shall discover whether, and to what extent, they may be improved. Savage rocks are too inhospitable to be permanently admitted, in any extent, near the eye. All rocks convey something of this idea that are not accompanied by vegetation; and, therefore, planting among or near them is, in every case, an improvement where trees do not exist. All rocks are expressive of dignity; those eminently so, are not greatly varied by projections from their surface: their beauty is to be augmented, either by increasing their surface in height or depth, or by connecting it if too scattered. The removal of a few feet of earth, or part of the bushes or trees from the bottom of a precipice or ridge, and the emplacement of a line of wood along its summit, will increase its real and apparent height; a similar process, with respect to the sides, will add to the idea of stability and continuation. If the parts are too much scattered, a few trees placed before, or bushes or creepers planted in the intervals between the parts, will connect them, and give the idea of a whole, partly concealed. But in this case, a considerable breadth of surface is necessary, at least in one place, otherwise dignity must give way to picturesque beauty. But the least indications of rocks that are not very fantastic in their form, even including such whose chief expression is picturesque beauty, are, to a certain degree, expressive of dignity. The slightest indication of a stratum or ledge appearing above the surface, conveys something of this idea, and ought not to be neglected. When they are discovered by alterations in the ground with a view to the formation of roads, fences, and water, or to the erection of buildings, occasional advantage may be taken of their appearance. A road across a declivity may be accompanied by a ledge of rocks instead of a bank of earth. Grounds which are broken and picturesque will display a more sufficient reason for the appearance. The walls of a terrace evidently in part founded on a rock, will give an idea of dryness, dignity, and security to the house; and the margin of a stream displaying even large stones, increases the idea of impetuosity; or, in lakes, of the action of water in washing away the earth. Among imitations of wild scenery, detached stones heighten the illusion, and carry back the mind to the aboriginal state of the country. Loose or detached fragments of rocks may often aid the effect of real or supposed masses. The appearance of a large rude stone near a wooded steep, unless of one evidently rounded by water or art, always leads the mind to the larger mass up the acclivity from which it has been broken and rolled down; if partly sunk in the ground, and concealed by vegetation, the fertility of the imagination considers them as parts of magnitudes which lie buried under the surface. All this, however, can only be successfully accomplished in a country which, by the character of its general surface, does not preclude the idea of rocks. On a flat or a champaign country, the want of truth, or seeming truth, would render them disagreeable; and, indeed, did rocks exist in such a landscape, they should be hidden rather than displayed, unless of such extraordinary magnitude and effect, as to form an exception to general principles.

7230. The judicious distribution of stones, in situations where they are not evidently foreign to the character of soil and surface, may greatly heighten wildness and picturesque beauty. (fig. 702.) Every thing, however, will depend on the manner in which this is done; they must not be merely laid down at random on the surface (a), or formally joined together (b), or merely connected, which, however, is better (c); but grouped with taste (d), and partially concealed by vegetation and sunk in the soil. (f, g).

7231. Fantastic stones (fig. 703. a) should be avoided in all cases, unless in some peculiar scene; and where there are already indications of stratified or regular masses of rock (b), it can never appear natural to place near them round, water-worn stones (c). Where angular and laminated stones are near; or where
such as can be quarried in forms suitable for building may be procured, grand effects may be produced; either by using them in forming imitations of nature, or by combining them in a mixed style of artificial form and natural conglomeration. (fig. 704.)

Sect. V. Buildings.

7232. Buildings, as materials of scenery, are entirely under the power of man; and, from that circumstance, were carried to an unwarrantable excess in the decline of the ancient, and the infancy of the modern style. Improvements on ground are forgotten by their effect; that of planting may be accounted too distant or too slow by ordinary minds; but a building is complete the moment it is finished. It affords immediate satisfaction to the owner; and being known as a costly object, full credit is given to him for the expense incurred. Thus wealth, confiding in its powers, multiplied garden-buildings to an excess, which ended in creating a disgust, still existing, in some degree, at their appearance in improved scenery. Before proceeding further, it may be proper to offer some remarks on the style or architecture of buildings.

7233. It is a common error to consider nothing as architecture but what is Grecian; to fancy that all architecture must have what are called orders; and to consider the Gothic, Chinese, or Hindoo modes of building, as mere barbarous compositions. But nothing can be more unphilosophical than this mode of viewing the subject; and it may just as well be said that there is no true language in the world but the Greek; that every language ought to correspond with it in the tenses and moods of the verbs; and that every other mode of speech is mere jargon. A style of building, and mode of oral communication, must have a sufficient claim to be considered as complete, when they answer the purposes for which they are intended; and, applying this principle to the architecture and language of different countries, we shall find that each is complete relatively to those countries. That any style of building, or any language can be universally suitable, is to suppose that the same climate and the same degree of civilisation prevails over the whole globe. Thus, as there are different languages, and different manners and customs, so there are different styles of architecture; and though we may prefer the Grecian, as having been used by the most refined nations of antiquity, let us not hastily reject every other style as devoid of congruity, or unsuitable for being applied to constructions of use or beauty.

7234. The origin of the different styles of architecture are usually traced to imitations of temporary structures formed of timber or of rough trees; and thus the Grecian column, with its capital ornamented with foliage, has been called an imitation of the trunk of a palm, with the petioles of its recently dropped leaves still adhering; the Gothic arches and tracery have been likened to wicker-work, or the intersecting branches of an avenue; and the Chinese style to the imitation of a tent supported by bamboo. But the imitation of nature is the last thing that occurs in the progress of improvement; and though the above opinions may not be without their use as a sort of hypothesis for composition; yet it appears much more probable that styles of building have taken their origin, jointly from the materials the country afforded, and the wants of the people. According to this hypothesis, the Grecian may be considered as founded on the use of planks of stone, in the same way as beams of timber (fig. 705. a); the Gothic, by the use of small stones, held together by their position (b); and the Hindoo, by the use of small stones, held together by superincumbent weight (c). The Doric temple (fig. 706.) is easily traced in this way to its prototype of wood; but though the idea be supported by the authority of Vitruvius, it should never be considered as anything more than mere conjecture.

7235. The progress which architecture has made in Britain, in modern times, is matter of greater certainty; and Repton, with his usual taste, has furnished an ingenious
vignette (fig. 707.), which indicates that the most remote style of domestic architecture, was that of the castellated Gothic; to which succeeded the ecclesiastical Gothic; next the style prevalent in the seventeenth century, being a mixture of Gothic and Grecian, commonly called the Elizabethan style; after that the Grecian; and last of all, the Hindoo, just coming into notice, and which he considers (Designs for the Pavilion at Brighton, &c. 1810) as likely to become fashionable.

The most suitable style for domestic purposes in Britain, he considers to be the Gothic, as admitting every description of interior form and arrangement, an unbounded variety in the external forms and lines, and as being favorable to future additions, without deranging the effect or ordnance of the original composition.

7236. With respect to the effects of buildings, as component parts of verdant scenery, Shenstone observes, that a landscape, to him, is never complete without a building or rocks; and certainly, considering it merely in the light of a picturesque view, a building, in addition to merely verdant scenery, forms a better picture, by giving a desirable feature or resting-place for the eye. Considered, however, in the light of natural expression, the meanness of root-houses and grottos, the absurdity of hermits' cells, heathen temples, triumphal arches, mock chapels, &c.; and the inutility of all of them, render them positive deformities in scenes of natural or picturesque beauty. They break in upon repose, simplicity, and all allusion to natural scenery by their frequency, and suggest ideas of ostentations vanity in the owner, rather than of propriety and elegance of taste. But though their excess is so general and so obnoxious, the occasional introduction of some sorts may be made with propriety. Garden-seats are necessary for shade or shelter; bridges, for communication between the banks of rivers or rills; cottages, gate or entrance lodges (fig. 708), as abodes for laborers; and open sheds as places of resort for cattle. Even a prospect-tower is a desirable object in a flat country, affording no other means of obtaining a bird's-eye view. A temple, after all, is in many cases but a garden-seat; and if beautiful in itself, and judiciously placed, we can see no objection to its introduction in the garden-scene of a princely mansion; certainly none to more than one of them, under the geometric style of planting. To raise a monument in memory of a great public character, or consecrate an urn to private friendship, or parental memory, can hardly be offensive to any mind. A sundial is both a useful and an agreeable object; and statues and busts, in highly polished scenery, by the contrast in the kind of beauty displayed, recall the mind for a moment, from contemplating the wide range of nature, to admire the hand of art concentrated in a single point. In this view there are various objects of this description admissible in the more polished scenes of gardens, &c., as marble fountains, fragments of antiquity, &c. But when simplicity and natural-like beauty are the prevailing idea, all works of art must interfere more or less with the idea; and unless they can be raised up and maintain a more interesting expression, they must be regarded as injurious rather than beautiful.

7237. But simplicity and nature, continually repeated, become tiresome in their turn, and man is then pleased to recognise the hand of art, if judiciously exercised, even
on an artificial ruin (fig. 709.); but then the execution must be such as to silence every idea as to its history; it must be so like truth as to interest by the likeness, not by deception, which is disgusting. Artificial ruins, however, need seldom be resorted to while there are so many other architectural and sculptural decorations to which we can have recourse. Nothing gives more general satisfaction than a neat and comfortable picturesque cottage (fig. 710.), with a good garden in neat order and cultivation; and such buildings may always be applied to some useful purpose, even in the grounds of small villas or fômes ornées. In more extensive scenes, cottages of different styles may be introduced from that of the Greenlander or Norwegian to the Hindoo; and there can be no reason why a proprietor, if he chooses to go to the expense, should not ornament the dwelling of an upper servant in any style he pleases, even that of a Chinese mandarin. (fig. 711.)

Sect. VI. Of the Accidental Accompaniments to the Materials of Landscape.

7238. Of accidental accompaniments the first are roads; and of roads, the principal is the approach. The approach, or road to the house, ought to display to advantage the beauties of that part of the place it passes through, and as many other beauties as may be displayed without showing the principal, which are generally those of the garden-front. In both styles, it ought to ascend to the house rather than descend, and pass along a flat or hollow rather than over inequalities of surface.

7239. The approach in the geometric style was generally a wooded avenue, in one or in several lines. In the modern, it is generally a bold, free, gently waving line; every turn of which is, or seems to be, produced either by some gentle variation in the surface, or by the position of a group of trees. It may pass through wood only, or through forest-like scenery. The first view obtained of the house ought to be as favorable as possible, and not of any particular front, but rather an angular view, bosomed in trees. The second, or if there are two or more, the last view, on a nearer approach, should be distinct, and show the entrance-front, and porch, or portico; the road approaching it at such a distance, obliquely, as that the eye may now readily comprehend the whole, and to the greatest advantage.

7240. In conducting the spectator to view objects, whether by approaches, roads, or walks, it is a matter of some nicety to determine à priori, the exact distance at which he should be permitted to obtain a full view. There is a certain point of distance from whence every object appears at its greatest magnitude. The apparent height of any object will
vary according to its distance, the inclination it makes with the horizon, and our relative elevation or depression. A correspondent of Repton states, that "any two of the above three things continuing the same, the apparent magnitude will decrease with the third, though not in exact proportion to it. Thus, the object being perpendicular to the horizon, and our elevation remaining the same, its apparent height will decrease with the distance. Our elevation and the distance remaining the same, the apparent height of the object will decrease with its inclination to the horizon. The inclination and distance being the same, the angle, or apparent height, will decrease with our elevation or depression, supposing our height was at first the middle point of the object. This last being liable to some exceptions, the general rule is, that the distance from the object, measured by a perpendicular to it, the point at which its apparent height will be greatest is, where the perpendicular from the eye falls upon the centre."

7241. The difficulty in this subject is to know what the conception is that we shall form of the height and magnitude of an object according to different circumstances; its apparent height, as well as its real height, remaining the same. This cannot be reduced to rules, but depends chiefly on a careful comparison of particular instances. One cause, Repton considers, may proceed from the position of the eye itself, which is so placed in most foreheads as to view a certain portion of the hemisphere without any motion of the head. This portion has been variously stated at from sixty to ninety degrees. The eye surveys more in breadth than in height; and more below the axis of vision (fig. 715. a) than above it. Much depends on the projection of the forehead and eyebrows, prominency of the eye, &c. in different individuals; yet the upper angle (a b) will seldom be greater than one half of the lower angle (a c); and Repton asserts, that he could not distinguish objects more than twenty eight degrees above his axis of vision, though he could distinctly see them fifty-one degrees below it. From hence, he concludes, "that the distance at which an object appears at its greatest height is, when the axis of vision, and the summit of the object, form an angle of about thirty degrees; because, under this angle, the eye perceives its full extent without moving the head." Thus, supposing the eye (fig. 715. a) to be five feet six inches from the ground, a tall object (b), at thirty feet distance, will be seen to the height of twenty feet; at fifty feet distance (c), to the height of thirty feet; at seventy feet distance (d), to the height of forty feet; at eighty-seven feet distance (e), to the height of fifty feet; and at a hundred and five feet distance (f), to the height of sixty feet. (Observations on Landscape Gardening, p. 21.)

7242. The approach in the modern style was well understood by Repton, and the following excellent observations by this artist seem to sum up every thing that can be said on the subject:— The road by which a stranger is supposed to pass through the park or lawn to the house is called an approach; and there seems the same relation betwixt the approach and the house externally, that there is internally betwixt the hall or entrance and the several apartments to which it leads. If the hall be too large or too small, too mean or too much ornamented for the style of the house, there is a manifest incongruity in the architecture, by which good taste will be offended; but if the hall be so situated as not to connect well with the several apartments to which it ought to lead, it will then be defective in point of convenience: so it is with respect to an approach; it ought to be convenient, interesting, and in strict harmony with the character and situation of the mansion to which it belongs.

First. It ought to be a road to the house, and to that principally.

Secondly. If it is not naturally the nearest road possible, it ought artificially to be made impossible to go nearer.

Thirdly. The artificial obstacles which make this road the nearest ought to appear natural.

Fourthly. Where an approach quits the high road, it ought not to break from it at right angles, or in such a manner as robs the entrance of importance, but rather at some bend of the public road, from whence a lodge or gate may be more conspicuous; and where the high road may appear to branch from the approach rather than the approach from the high road.

Fifthly. After the approach enters the park, it should avoid skirting along its boundary, which betrays the want of extent or unity of property.

Sixthly. The house, unless very large and magnificent, should not be seen at so great a distance as to make it appear much less than it really is.

Seventhly. The first view of the house should be from the most pleasing point of sight.

Eighthly. As soon as the house is visible from the approach, there should be no temptation to quit it (which will be ever the case if the road be at all circuitous), unless sufficient obstacles, such as water or inaccessible ground, appear to justify its course. (Enquiry into the Changes of Taste in Landscape Gard. p. 109.)

7243. Walks are the next accompaniment to home scenes, without which they cannot be viewed but in particular states of the weather and the surface. They were straight, angular, or in regular curves, in the geometric style, and are in easy natural-like lines in the modern manner. Though avowed objects of art, they ought always to bear a certain analogy to the scenes they pass through; with formal-kept hedges in highly finished scenery, and edges blending with the gravel in the picturesque manner, recommended by Price in more wild scenes. Taste must determine their general course, from the range of beauties to be displayed; and their particular turns, from local beauties and ac-
cidental circumstances. The principle of a sufficient reason ought never to be lost sight of in laying out walks and roads; that is, no deviation from a straight line should ever appear, for which a reason is not given in the position of the ground, trees, or other accompanying objects.

The fausest description of hill or mountain walk is where the path is carried along the declivity on a perfect level, or where it winds round the hill by a gradual and regular ascent, here crossing a smooth slope and never forcing its way through rugged rocks, always preserving the same easy ascent or descent. When the views from such walks are grand and extensive, and especially if they include part of a river, a lake, or the sea seen through a proper foreground of trees, nothing of the kind can be more noble.

Of valley walks, one on the wooded banks of a winding river, with cascades, or running over a rocky bed, the path sometimes accompanying the stream, at other times both retiring or separating from each other, till the sound of the water is scarcely heard through the wood, and then meeting again, accompanied by open glade or meadow, with the other variations of which such scenery is susceptible, may be reckoned among the finest of the kind.

7246. Fences are accompaniments common to both styles of landscape; they are either permanent or temporary, and, in both cases, have been treated of in considering the subject of planting (6820.) and wood. (7203.)

7247. Animated nature. Deer, wild and tame hares, cattle, sheep, game, singing birds, all belong to a residence, and are necessary to complete its beauty. Pheasants and other game, ranging undismayed by man, in garden-scenes, give a high idea of seclusion and removal from common nature; the finer sorts may be retained in appropriate structures (fig. 714.), and the common left to themselves, but liberally supplied with food. The cawing of rooks, the shrieking of the owl, the screams of peacocks, the notes of birds, are all desirable circumstances in certain situations, and ought to be attended to, by introducing such trees or plants as are favorable to their increase. The smoke of a cottage or a farm-house, the view of a distant village, the spire of a church, a water-mill, or a ruin, all become interesting in certain cases; and with a thousand other instances of natural expression, in a great measure beyond the reach of art, will be sought for, and turned to account by the judicious artist.

C H A P. III.

Of the Union of the Materials of Landscape-Gardening, in forming the constituent Parts of a Country-Residence.

7248. Having applied the principles of natural and relative beauty to the materials of gardening separately, we shall next apply the same principles to the formation of those scenes of use, convenience, or elegance, which form the constituent parts of a country-residence.

7249. The mansion and offices first demand attention, as the central feature of art and refinement. What relates to the design of these groups of buildings belongs to architecture; but the situation, aspect, style, and accompaniments are within our province. In determining the situation, a great variety of circumstances, some of a general, and others of a local or peculiar nature, require to be taken into consideration. Natural shelter, dry sub-soil, the view of the house from a distance, and the distant prospect seen from the house, belong to the former; and removal from the boundary of a public road, suitableness of the adjoining grounds for the garden-scenes which accompany mansions, trees already there, or so situated as to aid the effect, &c. belong to the latter. According to Repton, the choice of a situation ought to be founded on, "First, The natural character of the surrounding country: Secondly, The style, character, and size of the house: Thirdly, The aspects or exposure, both with regard to the sun and the prevalent winds of the country: Fourthly, The shape of the ground near the house: Fifthly, The views from the several apartments; and, Sixthly, the numerous objects of comfort; such as a dry soil, a supply of good water, proper space for offices, with various other conveniences essential to a mansion in the country; and which in a town may sometimes be dispensed with, or at least very differently disposed."

7250. To arrange these considerations according to their respective weight or influence is hardly possible; "this must depend on a comparison of one with the other, under a variety of circumstances; and even on
the partiality of individuals, in affixing different degrees of importance to each consideration. Hence it is obvious, that there can be no danger of sameness in any two designs conducted on principles thus established; since in every different situation some one or more of these considerations must predominate; and the most rational decision will result from a combined view of all the separate advantages or disadvantages to be foreseen from each. It was the custom of former times, in the choice of domestic situations, to let comfort and convenience prevail over every other consideration. Thus the ancient baronial castles were built on the summits of hills, in times when defence and security suggested the necessity of placing them there; and difficulty of access was a recommendation: but when this necessity no longer existed, (as mankind are always apt to fly from one extreme to the other,) houses were universally erected in the lowest situations, with a probable design to avoid those inconveniences to which lofty positions had been subject; hence the frequent sites of many large mansions, and particularly abbeys and monasteries, the residence of persons who were willing to sacrifice the beauty of prospect for the more solid and permanent advantages of habitable convenience; amongst which, shelter from wind, and a supply of water for store fishponds, were predominant considerations."  

Enquiry, &c. p. 83.)

7251. In hilly countries, or in any country where the surface is varied, the choice is generally on the south-east side of the latter (b), on a raised platform, the rising grounds behind being planted both for effect and shelter.

7252. The field of vision, or portion of landscape which the eye will comprehend, is a circumstance frequently mistaken in fixing a situation for a house; since a view seen from the windows of an apartment will materially differ from the same view seen in the open air. Much evidently depends on the thickness of the walls (fig. 716.), the width of the windows (a), and the distance of the spectator from the aperture. Near the centre of the room (b), the spectator will not enjoy above 20 or 30 degrees of vision; but close to the window (c) his eye will take in from 70 to 100 degrees. Hence, to obtain as much of the view from a room as possible, there should not only be windows on two sides of a room, but one in the angle, or an oblique or bow-window on each side, instead of the common form. (Obs. on Landscape Gardening, p. 24.)

7253. The aspect of the principal rooms deserves particular attention in every case, and most so in bleak or exposed situations. The south-east is most commonly the best for Britain (fig. 717.); and the south, and due east, the next best. The south-west, Repton considers the worst, because from that quarter it rains oftener than from any other; and the windows are dimmed, and the views obstructed, by the slightest shower, which will not be perceptible in the windows facing the south or east. A north aspect is gloomy, because deprived of sunshine; but it deserves to be remarked, that woods and other verdant objects look best when viewed from rooms so placed, because all plants are most luxuriant on the side next the sun. "The aspect due east," he considers, "nearly as bad as the north, because there the sun only shines while we are in bed; and the aspect due west is intolerable, from the excess of sun dazzling the eye through the greatest part of the day. From hence we may conclude, that a square house, placed with its fronts duly opposite to the cardinal points, will have one good and three bad aspects." (Fragments on Landscape Gardening, &c. p. 108.)

7254. A mansion for the country, if a mere square or oblong, will thus be deficient in point of aspect, and certainly in picturesque beauty, or variety of external forms, lights, and shades. An irregular plan, composed with a combined view to the situation, distant views, best aspects to the principal rooms, effect from different distant points, and as forming a whole with the groups of domestic offices and other architectural appendages or erections, will therefore be the best; and as the genius of the Gothic style of architecture is better adapted for this irregularity than the simplicity of the Grecian, or the regularity of the Roman styles, it has been justly considered the best for country-residences. Another advantage of an irregular style is, that it readily admits of additions in almost any direction.
7255. Convenience, as well as effect, require that every house ought to have an entrance-front, and a garden-front; and, in general cases, neither the latter, nor the views from the principal rooms, should be seen fully and completely, but from the windows and garden-scenery. Not to attend to this, is to destroy their contrasted effect, and cloy the appetite by disclosing all, or the greatest part of the beauties at once. The landscape which forms the back ground to a mansion, the trees which group with it, and the architectural terrace which forms its base, are to be considered as its accompaniments, and influenced more or less by its style. The classic pine and cedar should accompany the Greek and Roman architecture; and the hardly fir, the oak, or the lofty ash, the baronial castle.

7256. Terrace and conservatory. We observed, when treating of ground, and under the ancient style, that the design of the terrace must be jointly influenced by the magnitude and style of the house, the views from its windows, (that is, from the eye of a person seated in the middle of the principal rooms,) and the views of the house from a distance. In almost every case, more or less of architectural form will enter into these compositions. The level or levels will be supported partly by grassy slopes, but chiefly by stone walls, harmonising with the lines and forms of the house. These, in the Gothic style, may be furnished by battlements, gateways, oriels, pinnacles, &c.; or, on a very great scale, watch-towers may form very picturesque, characteristic, and useful additions. - The Grecian style may, in like manner, be finished by parapets, balustrades, and other Roman appendages.

7257. The breadth of terraces, and their height relatively to the level of the floor of the living-rooms, must depend jointly on the height of the floor of the living-rooms and the surface of the grounds or country to be seen over them. Too broad or too high a terrace will both have the effect of foreshortening a lawn with a declining surface, or concealing a near valley. The safest mode in doubtful cases is, not to form this appendage till after the principal floor is laid, and then to determine the details of the terrace by trial and correction.

7258. Narrow terraces are entirely occupied as promenades, and may be either gravelled or paved; and different levels, when they exist, connected by inclined planes or flights of steps. Where the breadth is more than is requisite for walks, the borders may be kept in turf with groups or marginal strips of flowers and low shrubs. In some cases, the terrace-walls may be so extended as to enclose ground sufficient for a level plot to be used as a bowling-green or a flower-garden. These are generally connected with one of the living-rooms or the conservatory, and to the latter is frequently joined an aviary and the entire range of botanic stores. Or, the aviary may be made an elegant detached building, so placed as to group with the house and other surrounding objects. An elegant structure of this sort (fig. 118) was designed by Repton for the grounds of the Pavilion at Brighton.

7259. The flower-garden should join both the conservatory and terrace; and, where the botanical stores do not join the conservatory and house, they, also the aviary and other appropriate buildings and decorations, should be placed here. (See 6076. and 6161.)

7260. The kitchen-garden should be placed near to, and connected with the flower-garden, with concealed entrances and roads leading to the domestic offices for culinary purposes, and to the stables and farm-buildings for manure. (See 2382.)

7261. The situation of the orchard should, all other circumstances being suitable, be near to the kitchen-garden; and between them may be properly placed the garden-er’s house, connected with the furnace, sheds, fruit-rooms, &c. (See 2527.)

7262. The lawn, or that breadth of mown turf formed in front of, or extending in different directions from, the garden-front of the house, is, in the geometrical style, varied by architectural forms, levels, and slopes; and in the modern by a picturesque or painter-like disposition of groups, placed so as to connect with the leading masses, and throw the lawn into an agreeable shape or shapes. In very small villas the lawn may embrace the garden or principal front of the house, without the intervention of terrace-scenery, and may be separated from the park, or park-like field, by a light wire fence; but in more extensive scenes it should embrace a terrace, or some avowedly artificial architectural basis to the mansion, and a sunk wall, as a distant separation, will be more dignified and permanent than any iron fence. The park may come close up to the terrace-garden, especially in a flat situation, or where the breadth of the terrace is considerable.

7263. The shrubbery generally connects the house and flower-gardens, and forms, strictly speaking, a part of the pleasure-ground scenery. It is a scene in which the object is to arrange a collection of foreign trees and shrubs in a dry border, generally on the north side of a walk, or in dug groups and patches. One very principal consideration is, to connect, partly in appearance only, the dug patches. The distinct unconnected obstruction of such scenes is justly reproved by Price, who gives excellent in-
structions for creating the beautiful picturesque among dug groups, and preserving all the polish and appearance of high keeping with the most delicate culture of the plants. (See 6187.)

7264. The pleasure-ground is a term applied generally to the kept ground and walks of a residence. Sometimes the walk merely passes, in a winding direction, through glades and groups of common scenery, kept polished by the scythe, and from whence cattle, &c. are excluded. At other times it includes a part of, or all the scenes above mentioned; and may include several others, as verdant amphitheatres, labyrinths, (fig. 719.) a Linnaean, Jussieuinean, American, French, or Dutch flower-garden, a garden of native, rock, mountain, or aquatic plants, picturesque flower-garden, or a Chinese garden, exhibiting only plants in flower, inserted in the ground, and removed to make room for others when the blossom begins to fade, &c.

7265. The park is a space devoted to the growth of timber, pasturage for deer, cattle, and sheep, and for adding grandeur and dignity to the mansion. On its extent and beauty, and on the magnitude and architectural design of the house, chiefly depend the reputation and character of the residence. In the geometric style, the more distant or concealed parts were subdivided into fields, surrounded by broad stripes or double rows, enclosed in walls or hedges, and the nearer parts were chiefly covered with wood, enclosing regular surfaces of pasturage. In the modern style, the scenery of a park is intended to resemble that of a scattered forest, the more polished glades and regular shapes of lawn being near the house, and the rougher parts towards the extremities. The paddocks or small enclosures are generally placed between the family stables and the farm, and form a sort of intermediate character.

7266. The farm, or that portion of agricultural surface, retained in the hands of the owner for private cultivation, was, in both styles, placed without, but adjoining the park; and when circumstances admitted, near to the paddocks. In some cases, on a moderate scale, part of the park constitutes the whole, or a part of the farm, and is kept in aration. The trees in this cultivated space are arranged in natural-like masses, so as to give the idea of part of a forest-scene subjected to the plough. When the park is extensive and truly forest-like, the effect of the whole is much improved by the contrast, and recalls to mind those charming scenes in the woody districts of Germany, where cultivation smiles in the glades and recesses of eternal forests.

7267. The riding, or drive, is a road indicated rather than formed, which passes through the most interesting and distant parts of a residence not seen in detail from the walks, and as far into the adjoining lands of wildness or cultivation, as the property of the owner extends. It is also frequently conducted as much farther as the disposition of adjoining proprietors permits, or the general face of the country renders desirable.

7268. Original arrangement. Though the above arrangement of the component parts of a residence will be found, in general, the most convenient on a flat surface, or one gently varied, we are far from recommending its universal adoption. Situations are always fertile in suggesting new ideas, which

"Start even from difficulties, strike from chance;"

and a mind already stored with a knowledge of every part of the subject, works from principles, and fortuitous suggestions, rather than models. We would rather see an original idea attempted than the most beautiful arrangement imitated.

---

Chap. IV.

Of the Union of the constituent Scenes in forming Gardens or Residences of particular Characters; and of laying out Public Gardens.

7269. To complete a country-residence is the end of all landscape-gardening, whether imitative or geometric. In the preceding chapter we have given a general idea of the parts or scenes, and their connection, which enter into a complete residence of the first order. We have now to notice their arrangements in different gradations of residences
and these, we must previously acknowledge, are so intimately blended, that we hardly know how to separate them, and give a distinctive character to each; every country-gentleman, from the occupier of the palace to the cottage, adopting such luxuriant scenes as suit his particular taste, without reference to any thing but his own desires; and this happy circumstance contributes, perhaps, as much as the difference of situations, to the variety in the beauty and style of British country-residences. Mansions, villas, temporary residences, cottages, and public gardens, may be said to include the leading distinctions. Public gardens are much less various than private ones, because there are fewer publics than individuals.

Sect. 1. On laying out Private Gardens, or Residences.

7270. The specific distinctions of private residences may be considered as the mansion and demesne, the villa, the farm, the temporary residence, and the cottage; but each of these branches out into a number of subspecies and varieties.

7271. The mansion and demesne. The characteristic of the mansion and demesne, is the demesne or surrounding lands in tenancy. Any residence of which the dwelling-house is of a higher character than that of the mansion and demesne, as the castle, abbey, and palace, has the same general arrangement in the grounds, and differs chiefly in extent, and in the arrangements of the courts and other exterior appendages of the house.

7272. As a specimen of this style, we shall give the arrangement at Michel Grove in Sussex, the residence of R. Walker, Esq. from the works of Repton:

7273. In determining the situation for a large house in the country, there are other circumstances to be considered besides the fences and appendages immediately contiguous. These have so often occurred, that I have established in imagination certain positions for each, which I have never found so capable of being realised as at Michel Grove.

7274. I would place the house, with the principal front, towards the south-east.

7275. I would place the offices behind the house; but as they occupy much more space, they will of course spread wider than the front. I would place the stables near the offices. I would place the kitchen-garden near the stables. I would put the house-farm buildings at rather a greater distance from the house; but these several objects should be so connected by back roads as to be easily accessible.

7276. I would bring the park to the very front of the house.

7277. I would keep the farm or land in tillage, whether for use or for experiment, behind the house; I would make the dressed pleasure-grounds to the right and left of the house, in places which would screen the unsightly appendages, and form a natural division between the park and the farm, with walks communicating to the garden and the farm.

7278. The villa may be nothing more than a park with a house of smaller size than that of the mansion and demesne, surrounded by a pleasure-ground, and with the usual gardens. Moderate extent and proximity to other villas, constitute the characteristic of this class of residences; but though adjoining lands are not necessary to the character, they do not, where they exist, change it, unless their extent be considerable. Two villas joined together often mutually aid each other in effect, especially as to water and trees. (fig. 720.)

7279. The villa farm. A villa being originally a farm-house, we think that the Roman arrangement, in which the farm-offices were joined to, or at least so near, as to form with it and the domestic offices one group of buildings, might be adopted as the characteristic distinction of this class of residences. The farm-buildings should, in that case, be dignified with more architectural design than when placed at a distance; but
still in due subordination to the mansion. Instead of deer, sheep may graze the park on the garden-front, separated from the house by an architectural barrier, or in some situations, with a platform of gravel, and walks and knots of flowers. A glacis of turf, with a light fence below the slope, will be sufficient protection from sheep or cattle, and not impede the view of the lawn from the windows. The entrance-front may be approached through grass fields, not separated with common hedges, but with picturesque fences (fig. 721.) in the modern, and double hedges and slips of planting in the geometric style. All or any part of the other constituent parts of a mansion and demesne residence, such as hot-houses, gardens, orchards, pleasure-grounds, &c. may or may not be added, according to its extent, and the particular taste of the proprietor.

7280. The ferme ornée differs from a common farm in having a better dwelling-house, neater approach, and one partly or entirely distinct from that which leads to the offices. It also differs as to the hedges, which are allowed to grow wild and irregular (fig. 722.), and are bordered on each side by a broad green drive, and sometimes by a gravel-walk and shrubs. It differs from a villa farm in having no park. A dry hilly soil is best suited for this description of residence, of which there are some fine examples in Surrey, Kent, and the Isle of Wight.

7281. Temporary residences, as marine villas, sporting or shooting boxes, seldom con-
tain much land attached. No hot-houses, and but little pleasure-ground is here required. What land there may be, should be applied to use rather than to beauty. Speaking of hunting-boxes, Marshall observes “a suit of paddocks should be seen from the house; and if a view of distant covers can be caught, the back ground will be complete. The stable, the kennel, the leaping-bar, are the appendages, in the construction of which simplicity, substantialness, and conveniency should prevail.”

7282. A cottage orné, we think, might be characterized by the garden-front opening into a picturesque orchard; or a lawn, varied by groups of fruit-trees, instead of a lawn or park planted with forest trees. It may contain any part of the scenes of the villa, at the will of the owner. If the situation of the house is elevated, so as to give a view from the principal rooms of a great part of the farm, it will be the more desirable. A desirable foundation for this improvement is an old English farmhouse; by adding to which one or two principal rooms, a very interesting group may be formed at little expense.

7283. Cottage en verger. An agreeable variety of this species sometimes adopted in France, consists in surrounding an enclosed space of one or two acres, with an irregular strip of walnut, cherry, chestnut, and other tall-growing trees (fig. 722. a) which produce both fruit and timber; and then planting the interior space (b) with the finer sorts of fruit-trees, especially pears and plums, as standards, on turf. Winding walks are led through the whole, and groups of flowers and kitchen-vegetables introduced.

7284. The citizen’s villa (fig. 723.) is a spot of one or more acres laid out in lawn and shrubbery, but without a kitchen-garden. As the space contained is very limited, and often under an acre, only the most select trees, shrubs, and flowers should be employed; and great part of the trees and shrubs should be evergreens. Seats and other decorations may be introduced, of the most select designs, and best workmanship; and what is of the last consequence, none but a good gardener should be employed in order to preserve the whole in the highest order and keeping, at every season of the year. Gardens or residences of this sort are almost peculiar to the neighborhood of London; and the occupant procures his culinary productions and fruits cheaper and better than he can grow them, from that first of all gardens, Covent-garden.

7285. The suburban villa (fig. 724.) is of limited extent, but contains a small kitchen-garden and stables, with a field planted either in the ancient style (a), or modern style (b); with a neat lawn, and groups of flowers (c). Such villas are occupied more by professional men and artists, than by the lesser merchants and rich tradesmen, who (those of the metropolis at least) prefer the citizen’s villa. When two or more of such villas can be formed adjoining each other, the happiest effects may be produced if
their owners act in concert at their first planting; and a sort of community of scenery may be enjoyed, without lessening individual privacy and comfort. On the contrary, a gain might result to each proprietor rather than otherwise; for if two villas, adjoining each other, are laid out in the modern style, then by placing the masses of wood of the one, against the masses of the other, less ground would require to be occupied in plantation by each. Office-buildings might be placed against, or near office-buildings, so as to be shut out, or partially concealed with less than the usual quantity of trees, and so on. In the ancient style, avenues and vistas might be contrived to pass through each other's grounds, and the ornamental objects which formed their termination, serving both parties, only half the usual number would require to be erected by each.

7286. The suburban house (fig. 725.) is a large commodious dwelling, in a village-like collection of houses, or streets, on the outskirts of the metropolis, or of large towns; and occupied as the constant residence of wealthy professional men or merchants. It has a carriage-entrance to the house and stables in front, and a small kitchen-garden behind.

7287. The house with carriage-entrance (fig. 726.) occurs very commonly in the suburban streets of large cities; it contains a small garden behind, not however sufficient to employ a gardener; and it is without stable or coach-house; the fore-court is varied by shrubs and a few trees, and the central circle of turf, ornamented with baskets of flowers or roses; and in the middle a statue, sundial, fountain, pond, or a cedar, or other evergreen tree.

7288. The house with covered entrance (fig. 727.) is similarly situated to the other, but generally further from town, to and from which the occupant passes by the local public conveyances. It contains a garden-court before, and a garden behind the house, like the other; but the former is entered by a porch (a), connected with the house by means of a glass or opaque roofed passage (b); and along the front of the house is an open veranda (c, c) communicating with a vestibule (d). This sort of suburban house is well suited for invalids, who may take exercise, and enjoy the plants under the glass roofs in rainy weather.

7289. The house and conservatory (fig. 728.) is similarly situated to the last, with one or two wings (a and b), as conservatories; or, the one a conservatory, and the other a botanic stove, or a vineyard. These communicate with the two principal living-rooms, and also with the fore-court (c); the latter entrance is that made use of by the gardener. Heat is supplied from the under-ground offices of the house; and if the latter is heated by hot air, in Sylvester's excellent manner, or by the more simple operation of steam, it will be accomplished so much the more readily
and effectually. They may be also lighted up by gas, if there is a public gasometer in the neighborhood.

7290. The house and flower-garden entrance (fig. 729.) requires a more airy situation than either of the three last varieties; and is generally situated in some road or street, a mile or two from town, or in some suburban hamlet. The flowers may be variously arranged, and may be either florists' flowers or herbaceous perennials, with a mixture of dwarf ornamental shrubs. A very complete mode is to grow the flowers in the garden behind the house, and bring them to the front as they come in flower. This sort of residence is well suited for retired tradesmen, who act as their own gardeners; and some fine examples are to be found at Hammersmith, Hampstead, and round Manchester. The French and Dutch, and also the Germans, excel in this kind of garden, and produce the most pleasing effects by a judicious combination of very few species of flowers. They take care to select such as are showy, of brilliant and distinct simple colors, as white and scarlet lilies, red and white roses, nasturtium, candy-tuft, daisy, larkspur, &c. They admit few yellows, or small scattered flowering plants; but study to have masses of the same colors and forms, contrasted by different colors also in masses. There are many fine gardens of this sort in Picardy and the Netherlands, and some in Hanover.

7291. The house and French parterre (fig. 730.) can hardly be considered a distinct variety from the last; though it differs in this, that the front garden of the latter contains turf around the flower-compartments, whereas the former is composed entirely of earth, and gravel, edged with box, or some other plant.

7292. The common front garden (fig. 731.) is a variety so well known as to require no description; but, like the six preceding varieties, it is introduced here chiefly to suggest, that these humble scenes may be greatly improved in design, and also in cultivation and keeping. There is little danger of the gardens of the wealthy being neglected; but it is of great importance to the advancement of gardening, that the art should be displayed to as great perfection as possible in those gardens which are most universal; which are continually under the eye of a large city population; seen by the whole country-inhabitants, when they visit the towns; and which chiefly come under the eye of foreigners.
The farmer's garden should not be placed adjoining the rack-yard, on account of the straw liable to be blown into it: and should be well enclosed to exclude poultry, pigs, and other domestic animals. Supposing the farm-buildings to occupy three sides of a square, and the farm-house to be placed in the middle of the south side, and the rack-yard to be placed beyond the north side; then the kitchen-garden may be placed adjoining the east or west side of the square; the grass-orchard, which may also be the drying-ground, and area for rearing young poultry, on the opposite and corresponding side; and a small flower-garden may serve as an entrance-court to the farm-house. But in the case of farmeries on a larger scale, where the house is detached from the court of offices, the three gardens should be united with a small portion of lawn, and a pond, so as to form about an acre (more or less, according to circumstances), of garden and pleasure-ground round the house. (fig. 662.) The part destined for the growth of culinary vegetables should be laid out in right-lined plots and borders; the orchard-trees planted in rows or quincunx; and the flowers and flowering shrubs arranged in groups or beds on turf. The most useful and prolific fruit-trees should be chosen; including some plants of hops, and one or two walnut or chestnut trees in the exposed side of the orchard, if the climate is such as will ripen their fruits. No class of men have it in their power to form and cultivate a garden of less expense than that of the farmer; but unfortunately few farmers have a taste for the subject; perhaps, because gardening is not sufficiently contrasted to agriculture, to afford the farmer that sort of relief sought for in recreative and pleasurable pursuits.

The laborers' cottage and garden. This may be reckoned too humble a country-residence for the consideration of the landscape-gardener; but we conceive it to be of very great importance to the general good, that these should be improved, and their inhabitants ameliorated. What we shall advance is founded on the principle, that whatever renders the cottager more comfortable and happy at home, will render him a better servant and subject, and in every respect a more valuable member of society. Besides, one of the most constantly occurring objects in the country is the laborer's cottage, whether detached by the road-side, or grouped in hamlets and villages; and therefore to render such buildings and their scenery more ornamental must, independently of every other consideration, be a laudable object.

The accommodation contained in the cottage, and the size of the garden, should, no doubt, be regulated by the family of the cottager, and the facilities afforded him by his line of employment to live well on the small revenue of a large family, &c. But we shall take the lowest case that can occur, and state what we consider to be the minimum of accommodation, which a humane employer in England would wish to be enjoyed by his serving laborer, even if he had no other family than his wife.

The whole space to be enclosed, including the garden and the site of the house, cannot be less than one eighth part of a statute acre. The cottage should, if possible, be placed in the centre, fronting the south-east, by which means, if it be a square or a parallelogram, the sun will shine on each of the four sides a part of every day in the year. Its door should be raised two steps above the level of the garden; its principal windows to the south-east. A gutter should be placed under the eaves, to prevent the ground, at the base of the walls, from receiving extreme moisture, and thus rendering the interior damp and unwholesome. The cottage should consist of the following parts:

1. A passage to the door. Two steps of stone, and prevent it from being blown in by the wind. On the smallest scale, two broad boards, or two slates or flag-stones, placed pediment-wise over the door will suffice.

2. A lobby, broad passage, or other space inside the door, to contain lumber, fuel, garden-tools, and to serve for a place of waiting, or working at coarse work, &c.

3. A cooking and living-room entered by the lobby or outer room; the fire-place, with an oven and small boiler, both included in a cast-iron grate.

4. A sleeping-room over the living-room, and entered by a stair from the lobby or outer room.

5. A garret, or children or lodger's sleeping-room, or small room for any purpose, over the lobby or outer room.

6. A pentry, taken off the lobby, with a small window to the north-west.

7. A closet, for utensils and articles used in the living-room, taken off that room, with a window to the north-west or south-east.

8. A hen-roost, forming part of the garret over the lobby, and entered by a poultry-ladder, placed against the wall near the bottom of the outer wall.

9. In the garden should be a well, with a pump, if deep; unless some other source of good water be near.

10. A water-closet placed in a hidden part of the garden, behind the house, so contrived that the visitor may not, either from the windows of the cottage or the public road, with a going and returning, or an incidental approach, instead of the direct cou de sac paths which commonly lead to such places.

11. Planted beside the house, may be placed: pears, apples, plums, blackberries, and currants, in small plots, not more than a yard broad, planted by the hand. And so on.

The surrounding fencce may be a wall, close pales, a holly, thorn, sallow, or damson-plum hedge, according to circumstances; if a hedge of any kind, then standard plum, pear, apple, or cherry trees, may be planted in it; if a wall, the same sorts may be trained against it. Next to the fence, a border should be carried round the whole; a similar border may be formed round the house; and the area for culture within be thrown into two compartments, one behind the house, and one in front of it. The compartments may be surrounded with a line of gooseberries and currants, and a few standard apples or plums (as being the two most useful cottage fruits) scattered over the whole. Against the house may be planted currants, pears, or other fruits. Hemmed in, the situation is most agreeable. Here and there a small shrubbery, planted next the porch; ivy against the water-closet; and the scented clematis against the pigsty. The border round the house should be devoted to savory pot-herbs, as parsley, thyme, mint, chives, &c. and to flowers and low flowering shrubs. The surrounding border, under the wall or hedge, should be devoted to early and late culinary crops, as early potatoes, peas, turnips, kidney-beans, &c. No forest trees, especially the ash.
PRACTICE OF GARDENING. Part III.

and elm, should be planted in, or if possible, even near the cottage's garden; as these are ruinous to crops; the first both by their shade and roots, and the latter by its roots, which spread rapidly to a great extent, close under the surface. The oak is the tree the least injurious to gardens.

3731. Variation may be made in this extent of accommodation, by adopting a different form for the ground-plan of the plot; by different inclinations of surfaces, kinds of fence, sort of materials used for the roof and walls of the house, coloring of the walls, and above all, by adopting different styles of architecture. But whatever is done in this respect, no attempt at ornament or picturesque effect should be made which is at variance with comfort; — latticed windows are cold and comfortable; chimney-flues tortured in their direction, with a view to fixing the stack of chimney-tops in some particular point, occasion smoky apartments. A variety of other deviations from common practice made to gratify the eye of the beholder, without any reference to the inhabitant, might be mentioned; but we shall only add, that whatever is most comfortable and durable will please the best in the long run.

Sect. II. Public Gardens.

7312. Public gardens are either designed for recreation, instruction, or commercial purposes. The first include equestrian and pedestrian promenades; the second, botanical and experimental gardens; and the third, public nurseries, market-gardens, florists' gardens, orchards, seed-gardens, and herb-gardens.

Subsect. 1. Public Gardens for Recreation.

7313. Public parks, or equestrian promenades, are valuable appendages to large cities. Extent and a free air are the principal requisites, and the roads should be arranged so as to produce few intersections; but at the same time so as carriages may make either the tour of the whole scene, or adopt a shorter tour at pleasure. In the course of long roads, there ought to be occasional bays or side expansions to admit of carriages separating from the course, halting or turning. Where such promenades are very extensive, they are furnished with places of accommodation and refreshment, both for men and horses; this is a valued part of their arrangement for occasional visitors from a distance, or in hired vehicles. Our continental neighbors have hitherto greatly excelled us in this department of gardening; almost every town of consequence having its promenades for the citizens à cheval and also au pied. Till lately, Hyde Park, at London, and a spot called the Meadows, near Edinburgh, were the only equestrian gardens in Britain; and neither were well arranged. But in 1810, the Regent’s Park was commenced from a suggestion of W. Fordyce, Esq., the late surveyor of woods and forests, and it promises to be a scene worthy of the metropolis. It is only to be regretted, that the space available to the public is so much curtailed by interspersed villas, and surrounding rows of houses and gardens; for though from the number of trees, the wealthy citizen who can view the scenery from his horse or coach may recognise the park character; yet by rendering so great an extent of the surface private property, the wanderings of the pedestrian are limited, and his views of the scenery confined.

7314. The public garden of Carlsruhe (fig. 752.), and the town, founded by the Margrave Charles William in 1715, are formed to correspond with each other. The palace (a) is noticed by Sulzer (Théorie des beaux Arts, &c.) and by Hirschfield (Théorie des Jardins, &c. vol. iv. p. 416.), as one of the finest in Germany, and remarkable for having the wings at an oblique angle to the main building. Behind, exactly in the centre of the circular carriage-promenade (b), is a tower (c), which commands a bird's-eye view of the whole park, pleasure and kitchen gardens (d), and the town and church (e). The whole is on level ground, and joined to a natural forest. In the town, many English and other foreign artisans were settled. Among the trees near the palace, are some of the finest old tulip-trees, planes, bigonias, sumachs, acacias, cedars, and other exotic trees in Germany.

7315. Boulevards (Boulevard, Fr., or round work; a bulwark, or great bastion, or ram-
part, generally round). Many of the continental cities have a species of equestrian promenade within their boundaries, which is deserving of imitation. These are broad roads, accompanied by rows of trees, near the margin of the city, originally formed on the ramparts, or surrounding fortifications, and completely encircling it. They are highly interesting promenades, especially to a stranger, to whom they give an idea of the topography and most remarkable points of the scene in the most agreeable manner. The boulevards at Paris, Vienna, and Moscow, are particularly to be admired in these respects.

7316. A promenade might be formed in the margin of London, of a very interesting kind, by continuing the street called the New Road through Hyde Park, entering close to where Kensington Gardens leave off, proceeding thence across the Serpentine River, and coming out exactly opposite Sloane-street: then along this street and part of the King's Road, to the road leading to Vauxhall Bridge; from this bridge along roads already formed, and as may be seen by the map, well suited to lead to Blackheath; then turn towards London through Greenwich Park, so as to display the best views of the metropolis over Greenwich Hospital; form a viaduct or road, on a cast-iron colonnade, across the river, sufficiently high to admit ships in full sail to pass under: descend this, and join the City Road, which joins the New Road, and completes the circle. This course which, with the exception of the bridge, might be formed at no great expense or derangement of property, would give a grand view of the metropolis, and by now and then deviating from the direct road and returning to it, Kensington Gardens, Hammer-smith Nursery, the King's Road Gardens, Chelsea Garden, the garden of Lodgges at Hackney, the Regent's Park, Highgate, Hampstead, and all the most interesting gardens, scenery, and objects close to London, might be rapidly glanced at in one day.

7317. Mountain promenade. One of the finest equestrian promenades that can be imagined might be formed on the hill of Arthur's Seat, Edinburgh. From the base at Holyrood Park, let a road ascend winding round the hill, including the appendage of Salisbury Craig's, and the knoll to the east, if desirable, to the summit, at a rise not greater than two inches in six feet. Having arrived at the summit, let it wind down again at a similar slope, intersecting the other road, and arriving also at Holyrood Park. Then let or sell the ground to individuals to build on or plant, each according to his taste. The slope of the road would be found so gradual that a two-wheeled chaise might be driven up or down at a trot, which can be done on the Simplon road, where the slope is 2½ inches in six feet. Taking the height of the hill from the park at 700 feet, this would give less than five miles of ascending promenade, and the same number descending. By the formation of these two roads, hundreds of the finest situations in the world, for summer villas and cottages would be formed, and probably in time let or sold, so as to cover much more than the expense, both of purchasing the hill as it now is, and forming the roads in the very best manner.

7318. Public gardens, or pedestrian promenades. These, with very few exceptions, have been in all ages and countries laid out in the geometric style. The Academus at Athens is an ancient example. The summer garden at Petersburgh, a modern one. Even in China, where irregularity in gardening is so much desired in general, Ellis (Journal of the Embassy of 1816) informs us, that the late gardens at Canton, the result of the fashionable, consist of straight walks." And however much our gardening has been praised and copied by private persons on the continent of Europe, yet, with the exception of Count Rumford's walk at Munich, and the late Earl of Findlater's at Carlsbad, almost all the others are very properly in straight lines. The object of public gardens is less to display beautiful scenery than to afford a free wholesome air, and an ample uninterrupted promenade, cool and shaded in summer, and warm and sheltered in spring and winter. In a limited extent, these must be attempted in one principal walk, which, for that purpose, should as much as possible be laid out in a north and south direction. In more extensive scenes, certain covered walks may be devoted to summer, and certain east and west open walks, to spring and winter. The broad open, and narrow covered avenues of the ancient style are valuable resources on a large scale; these conjoined and laid out in a south and north direction, give in the centre an open, sheltered, sunshine walk in mid-winter; and a close or covered avenue being lined out along each side of the open central one, will afford shady walks for summer, and occasional places of retreat from casual showers in spring. Oxford and Cambridge afford some fine open and covered avenues, though far inferior to many on the continent.

7319. Public squares, of such magnitude as to admit of being laid out in ample walks, open and shady, are almost peculiar to Britain. The grand object is to get as extended a line of uninterrupted promenade as is possible within the given limits. A walk parallel to the boundary fence, and at a short distance within it, evidently includes the maximum of extent; but if the enclosure is small, the rapid succession of angles and turns becomes extremely disagreeable, and continually breaks in upon the par.
des promeneurs, the conversation of a party, or individual contemplation. The angles, therefore, must be avoided, by rounding them off in a large square; in a small one, by forming the walk into a circle; and in a small parallelogram, by adopting an oval form. In laying out a large square (fig. 733.), four objects ought to be kept in view: 1. Sufficient open space (a), both of lawn and walk, so as the parents, looking from the windows of the houses which surround the square, may not long at a time lose sight of their children: 2. An open walk, exposed to the sun, for winter and spring (b): 3. A walk shaded by trees, but airy for summer (c): 4. Resting-places (d); and a central covered seat and retreat (e), which, being nearly equidistant from every point may be readily gained in case of a sudden shower, &c. The statues of eminent public men are obvious and appropriate decorations for squares.

7320. Russell Square, laid out from a design of Repton in 1810, is one of the most complete in these respects. It has been objected as over-planted; but this is only a piece of vulgar injustice, applied indiscriminately to every rural artist, all of whom, as a matter of course, conclude, that when magnitude of object is the purpose of the work, the superfuous plants will root out and be destroyed. (r) Sloane Square is very ingeniously laid out as a botanic garden, which means the surrounding inhabitants have an easy opportunity of blending recreation with instruction. This plot being a parallelogram or long square, and the ground being low, Repton proposed to form it to a winding valley, containing a piece of water; the walks to be winding, the trees grouped, and the whole to be winded to produce an appearance of nature in the midst of art; but his advice was not complied with. The late poet-laureate, Pye (Essay,) purposed to lay out a square, in imitation of a wild overgrown quarry or gravel-pit, and plant it with thorns, hollies, furze, brambles, ferns, &c. This mode he would adopt on account of its originality. (rf) Edward’s Square, Kensington, was laid out, in 1810, in groups and winding walks, in a manner different from most other squares, by Aiglio, an eminent landscape-painter. A small city square might be laid out in terraces, like the Isola Bella, or the gardens of Babylon, and the space beneath usefully disposed of as vaults for goods, or a cart-market.

SUBJECT 2. Public Gardens of Instruction.

7323. Botanic gardens. The primary object of botanic gardens is to exhibit a collection of plants for the improvement of botanical science; a secondary object to exhibit living specimens of such plants as are useful in medicine, agriculture, and other arts; and a third is, or ought to be, the acclimating of foreign plants, and their dissemination over the country. In choosing a situation for a botanic garden, the leading object must be proximity to the town, city, or university to which it is to belong; and the next, if attainable, a variety of surface and soil, to aid the necessary formation of composts and aspects for different plants. In general, however, there is little choice in these respects, it being sufficiently difficult to procure an adequate extent of surface of any kind near large towns. As the leading object or feature in the view of a botanic garden is the range of hot-houses; and as these must always face the south, it is generally desirable that ground on the north side of the principal public street or road by which it is to be approached, should be preferred to ground on the south side. In the latter case, the hot-houses must be approached from behind, and then the spectator must turn round to look at them, by which their grand effect is lost. The Liverpool and Oxford gardens are in this respect unfortunate; that of Edinburgh fortunate.

7324. The extent requisite for a botanic garden depends upon that of the collection intended to be formed; as well as on the magnitude to which the tree-plants are intended to be grown. A good deal will depend also on whether tender exotics are to be principal or secondary objects of collection, and also on the manner of growing the hardy herbaceous plants. An immense collection of herbaceous plants may be included in a small space, if the soil is loamy, richly inclined to moisture, and if the plants are separated from each other in the rows by bricks or thin tiles, which at once completely divides them and stints their growth, so as to admit a great number being planted on the same space. The extent of the Chelsea garden is little more than three acres; that of the Liverpool garden is five acres; and in both are extensive collections. Messrs. Lodgdes have above a thousand species of herbaceous plants, which they keep constantly in small pots, set on beds of scoria. These occupy very little space, and the plants thrive well. Of course the larger-growing kinds are excluded.

7325. The form of a botanic garden is a matter of very little consequence: where the extent is small, a square or parallelogram may undoubtedly be made to contain most plants; but where it exceeds four or five acres, any form will answer; and, indeed, if there is a sufficient quantity of ground, the more irregular the form, so much the more variety will there be in the circumferential walks of the garden. The Chelsea, Cambridge, Oxford, and Edinburgh gardens, are square, or nearly so; those at Liverpool, Glasgow, Hull, and the Dublin Society’s garden, are irregular. The two latter both in outline and surface. The most irregular botanic gardens, both as to form and surface, with which we are acquainted, are those at Konigsberg and Warsaw. A small rill runs through the former, with the most irregular wavy banks on each side; and the latter is on the steep, broken, and almost inaccessible banks of the Vistula.

7326. In laying out the area of a botanic garden, the objects already mentioned, and various others, must be kept in view. If it be merely desired to have a general collection, then a surrounding border for the trees and shrubs; internal compartments for the
beds of herbaceous plants; and a space at one end or side for the hot-houses, frames, compost-yard, &c. will be sufficient; surrounding the whole with a walk, which may also cross the garden in one or more places. Such a walk to display in succession every remarkable feature, is essential to all gardens, whatever may be their extent or kind.

7327. In a complete botanic garden, the following seem to be requisites:—

1. A _carinse_ house, with seed-rooms, office for business, library, and a large room for conserving and forming plants. This is most generally situated at or near the entrance of the garden. Some consider it preferable to place a lodge at the entrance for the under-gardener, and to place the library and other conveniences above, in connection with the range of hot-houses; and this the more especially as botanic gardens are rarely family men, at least in Britain.

2. A range of hot-houses, either in one line, or in a semicircle, square, half circle, or oval, and other circumstances; with back sheds for all the usual purposes of hot-houses, and all other arrangements, giving rooms for every purpose, and no lodge; and lodgings for one man, even if there is a lodge, in order to attend to the trees.

3. An adjoining arrangement of pits and frames, but not in front of the range of hot-houses, as in a nursery.

4. A compost-ground for all the usual purposes.

5. An _aquarium_, including a bog, pond, spring, and salt-water fish, for marine algae.

6. A rock-work and under-pendent walls, tunnels, vaults, caves, open in different directions and degrees for the growth of mosses, ferns, fungi, &c.

7. Borders, shaded and kept moist in different degrees for plants that require the presence of other plants, and also in arrangements.

8. A _fungi-ground_, shaded by trees or vaults, and containing stamps and races of trees of different kinds, and other means for the preservation, as far as art will go, of a collection of native and other fungi, and mosses.

9. An _American_, or _log-earth_ ground, either a border, or connected groups, or a composite figure surrounded by walks.

10. A _drying-ground_, or paved area, for setting out the greenhouse plants in summer for air and exercise, and wind. In the pavement there may be holes, in which to insert iron rods to be connected with wires, to which to tie the taller and moreflexible plants.

11. A _grass-ground or granivarium_, for bringing all the grasses together.

12. A compartment for the plants used in medicine, according to the Pharmacopoeias of the different universities, &c.

13. A _carinse_ for the hardest _polonium_ plants.

14. Compartments for the plants and trees used in _agriculture_, _horticulture_, _dyery_, and other branches of general economy.

15. A compartment for _fioriates_ and border flowers.

16. A _compartments_ or, what is generally preferable, surrounding border or bed, for trees and shrubs.

7325. Various other _sub-arrangements_ or compartments of this nature may be contrived, as for creeping plants, climbing natives of particular countries, succulents, bulbs, &c.; and the association of plants in this way by strong natural and artificial (alluding to their use) affinities, is well calculated to facilitate both their culture and study. The most complete arrangements of this kind are to be found in the Paris, Dublin Society's, and Glasgow gardens. The size and shape of these sub-arrangements will, of course, be various, which will add greatly to the interest of the walks. They will, in general, be most advantageously placed round the outsides of the garden, within the marginal plantation, and should be separated by different sorts of rustic walls, or mounds of rock-work, hedges, thickets of evergreens, and other means. They should all be connected by a walk in such a way as that a general spectator may see each scene without being obliged to enter minutely into it; and that whilst none can escape the botanist, he may have an easy opportunity of entering minutely into each or any of them.

7329. The _central, or principal part of the ground_, should be devoted to one general arrangement of all the phanerogamous plants, including hardy exotic trees and natives. The trees may be kept dwarfed, by being propagated from cuttings, or layers, and by planting in pots, and pruning; and the stowe, and other exotics, will of course only be plunged in their appropriate places for a few weeks in the warmest part of each summer, as in the Paris garden. Every plant ought to have its name painted on strong cast-iron tallies, on a bevelled face, in letters so large as to be legible without stooping. If to the name, systematic and English, could be added the _Linnaeae_ and _Jussieianae_ class, native country, and time of flowering, it would obviously greatly facilitate the periopathic study of plants. The tallies once placed there, should never be removed, excepting when the arrangement is to be enlarged, because the name will show that the plant exists, or ought to exist, somewhere in the garden; and will or ought to be placed there in the proper season. Such a collection should, in short, be a transcript of the catalogue of the garden; some of the filices, and most of the fungi, alge, and musci excepted.

7330. Whether the arrangement in the compartments or main area of such a general collection ought to be _Jussieianae_ or _Linnaeae_, must depend on the opinion of those concerned. In the present state of botanical science, that of _Linnaeus_ is the best for the study of nomenclature and technology; it is that generally adopted in Britain and the north of Europe; whilst that of _Jussieu_ is almost universally adopted in France and Italy.

7331. The _botanical arrangement_ in the _hot-houses_, and as far as that kind of arrangement is applicable, in the different subsidiary or _habitat_ arrangements, should, in our opinion, decidedly be _Jussieianae_, as presenting the strongest natural affinities, and calculated to promote variety in general appearance, facility in recollecting names, and often answering as to _kind_ of culture. The Paris garden is the most complete in Europe as to comprehensive arrangement; though the collection of plants is inferior to that at Kew or Liverpool. It is remarkable for its menagerie, containing a collection of living animals of many kinds, lodged in appropriate buildings with surrounding enclosures of different degrees of extent. It also contains specimens of all the different soils, composts, and operations of horticulture and agriculture. A plan of this garden, which contains about seventy acres, and was arranged in its present form by the chevalier Molinos, has been given by Professor Thouin, in the _Annales du Muséum_; and another published more recently by the professor's brother, G. Thouin (Artiste Jardinier), in _Plans Raisonnées des Jardins, &c._ This plan (fig. 734.) not only contains the iconography of the garden (1 to 21), but in the margin are placed elevations (22 to 42) of the houses in which the living animals are kept, of the immense buildings in which the
The entrance to the garden is through a handsome iron railing between lodges (1, and the elevation 32), opposite the bridge of Austerlitz (42). On the left is the menagerie, commencing with the ferocious animals, in a long building, with wings and a fore court; and next in order is a number of small irregular-shaped enclosures of pasture, covered by trees, each devoted to one genus of animals, and containing a building in the centre for their repose or shelter (2 and 3). Passing these we arrive at the dwelling-houses of the professors of natural history; and the large amphitheatre (4, and elevation 26) in which the lectures are given. Here is also the hot-house department (7, and elevation 23), with a sunk area in front for pots and frames; a space called the seed-garden for raising seeds, and for nursing them till they flower. Adjoining is an artificial mount, crowned with a kiosque (5), which overlooks, not only the whole garden, but great part of Paris; it contains a sundial, which, by means of a lens, is contrived to discharge a cannon every day at noon. The museum of natural history is a large building at the upper end of the garden, exactly opposite the entrance (6, and elevation 24); it is separated by a handsome low wall and iron rails from the open garden, which consists of 36 plots, enclosed by lattice-work from the walks, which are at all times open to the public. These plots contain specimens of the mode of propagating all herbaceous vegetables, all trees and shrubs (8) — a department which is particularly rich in specimens of grafting and incarching (9); a large basin for aquatics, and aquatic birds and reptiles, situated at the bottom of an excavation, more than ten
feet below the level of the general surface of the garden (10); the sides of this excavation are planted with marsh trees and shrubs. The next divisions consist of florists' flowers arranged according to their colors and times of flowering (11); medicinal plants (12); illustrations of the operations on plants, as the different kinds of hedges, live fences, rows, &c. (13); all the sorts of fruit-trees, vines, and of vines and flowers in the order of France, with different modes of pruning and training them (14); all the sorts of vegetables used in rural economy throughout Europe, the more tender sorts, as the convolvulus batatas, being protected early in the season by glass (15). The general arrangement of all the plots in France, tender, and hardy, occupies ten plots (16); this classical adoption is that of Jussieu. The tender species are brought from the hot-houses in June, and plunged in their places in the beds, where they remain till September; the hardy tree and shrub kinds are kept dwarf by pruning, and brought into flower by ringing. The different sorts of annual plants, and the mode of raising seeds of every kind, is displayed in a large plot (16). There is a general arboretum (17); one of winter or evergreen trees (19); of trees in perfection in autumn (20); of summer trees (21); and of spring trees.

3.355. The principal buildings are the menagerie for ferocious animals (22); the conservatory (23); museum of birds (24); lodge for East India Company; lecture-theatre (25); near which is situated the office of administration for the garden; retreat for buffaloes (27); stable for the equus tribe, with pigeon-house over (28); Merino and other sheep-cots (29); cot for goats (30), for camels (31), for elephants (32), for foreign oxen (37), for red deer (39), for the dromedary (40), for packing plants (41), and for a public coffee and restaurant (42) at the base of the mountain (38); the new mount (21), also a number of other buildings of less note; and so complete is this establishment, that in some of the areas destined to show certain branches of culture, there are lodges containing specimens of all the implements in use in that branch. (Annales du Musée; Roger's Descriptive History of the Park Gardens.)

7334. In the office of administration, which is remarkably complete, is the botanical cabinet (fig. 7335), thus described in the Horticultural Tour: "In the staircase [a] is preserved a tall palm-stein from South America, which had been naturally clasped in a very extraordinary way by some liane or twining shrub, and evidently strangled by the deeply indented grasp of its invader. Professor Desfontaines' working-room (b) adjoins, and next, the working-room for the propagating assistants [c]. Here, the female, of the tall and unblemished flowers, was employed in fixing dried species of plants to sheets of white paper, after they had been arranged for that purpose by Professor Desfontaines. There is a room [d] appropriated to the keeping of the specimens of dried plants. They are contained in close prostrate boxes, which are accurately and conveniently arranged, that the specimens composing any particular genus can be produced for examination the moment they are called for. Another [e] contains specimens of wood of very many species of trees, we believe of almost all that are figured in the quarto volume published by Dr. Rutty in 1775, and many unprinted wood by Dr. Houtt, and others of the Dutchmen. The samples are in general smoothed with the plane, the better to display the grain, and the extreme beauty of some kinds. A vase, nicely formed out of the stem of a date-palm, is a curious object. It is about a foot and a half in diameter, and somewhat more in height. A large apartment [f], extending the whole breadth of the building, contains the seeds and seed-vessels of plants, with specimens of vegetable products in general. In the same room several commodious presses and drawers are appropriated to the reception of the seeds saved in the garden from the more rare or tender plants, particularly those of only annual duration. We may add, that the great attention paid to this part of the business of the garden, the saving of seeds, and keeping them in the nearest order, received our unqualified approbation. A glazed frame containing numerous skeletons of leaves and flowers, had a very pretty and unusual effect. Fronds of the large umbrella-palm of Ceylon (Corypha umbrosaflora) decorate the ceilings of two of the rooms." (Hort. Tour, 353.)

Subsect. 3. Commercial Gardens.

7335. Public nursery-gardens come first in order. In choosing a situation in which to establish a nursery business, two points are to be considered, fitness as to the disposal of the produce, and fitness as to shelter, aspect, and soil. Where it is intended to attempt a general nursery business, regard must be had to the leading roads of the district, the means of carriage by land or water, the kind of objects that will be most in demand, whether seedlings, fruit-trees, or tender exotics, or all of these. Where a local business is to be commenced, it is evident much will depend on the choice of a conspicuous situation in some line of road of general resort, and as near as possible to some town or city. As far as respects shelter, aspect, and soil, the remarks already submitted in reference to private nurseries (6974.) may suffice. The best general soil is evidently a free tender loam; and the best general aspect or exposure, one inclining to the north; as precocity is no advantage in a nursery, but the contrary, and all seedlings and tender plants will be the safer till they come up, and come up more vigorously, when brought on not so much by the direct rays of the sun as by his indirect influence on the atmosphere. Another great advantage of a northern exposure is, that plants and trees may be taken up, as well as planted, later in the season, than in one of a contrary nature. Granting also, and making good deficiencies and other nursery-operations, which are generally referred to the last moment, may be done with less injury to the trees and plants.

7336. The extent of a nursery must depend on the means of the occupier, and the probable extent of market. It will also depend, in some degree, on the kind of articles to be chiefly cultivated, and the mode of cultivation to be pursued. Where manure is scarce, such a system of alternate nursery and market-garden crops must be adopted as shall preserve the ground in heart; but where manure is more abundant the severe crops may succeed one another more closely. Where thorns and seedling forest-trees are to be the chief articles grown, it is evident less ground will be required than when transplanted forest-trees are to be the chief article produced.

7337. In laying out a nursery, the objects to be cultivated, and the kind of business to be expected, must be leading guides in the design, and the duration of the tenure will naturally have a material influence on the execution. The following seem objects desirable for a complete nursery:
7338. The dwelling-house of the master; this in a nursery for local demand, and in which public attraction is an object, ought to be placed near the road; and at the same time as centrically as possible in other respects, the objects being to be elevated to their upright forms may command, as far as practicable, the whole nursery; but, at all events, the following objects, more or less:

7339. A seed-shop and counting-house or office, which should be connected with the house for the master's convenience; but, at the same time, have each distinct entrances. The counting-house should have a good clock, and a type of chain communicating to a bell placed over, or in some conspicuous situation for regulating the hours of labor; also a speaking-pipe to the packing-court and centre of the hot-houses.

7340. A journeyman's living-room, and a number of sleeping-rooms for the whole or a part of the journeymen employed by the year, or otherwise, communicating with the packing-court, or in some cases, on a small scale, occupying part of the ground-floor of the house. From this appendage should be a speaking-pipe and bell to communicate with the counting-house and the master's sleeping-room.

7341. A centrally conventional and proper yard, arranges, communicating with the seed-shop. The tools should be at least weekly examined by the foreman before paying the men. The larger number-sticks or tallies, not in use, should also be kept here.

7342. A museum and herbarium-room, in which models (in plaster, Roman cement, or papier mâché) of all the different and dried specimens of all or most of the plants grown in the nursery, should be kept, in order to show to purchasers, in seasons when the plants to be purchased are not in fruit or in flower.

7343. Packing-sheds, surrounding a part or three sides of a packing-court, one of these being open to, or commanded by, the windows of the office and common living-room of the house. Over these should be a range of seed and store lofts.

7344. A stable, cart-shed, cowhouse, and pigsty, if such conveniences are desired, communicating on one side with the packing-court, and on the other with the wall: a coal-shed, a horsedung-heaep, and other similar objects in the back area of the dwelling-house.

7345. A store-ground, or laying-in-ground, three or more times the size of the packing-court, in which to immerse the roots of plants taken up, to be ready for sale or packing.

7346. A plot for the hot-houses, square, octagonal, or polygonal in the circumference or boundary, and to the same figures, the living-rooms ought to be elevated, so that their windows may set out the green-house plants during summer. If the whole boundary cannot be at once, or perhaps not at all, covered with glass, the naked part may be a wall for training fruit-trees, and the north border for auricular frames or stages, striking cuttings, &c. But in a general nursery, the whole of the boundary of a square may be well adapted for the same purpose, the centre; that of northern aspect being well adapted for striking plants, and preserving, or retarding such as are in flower. The exterior of this boundary line should be arranged for pots, potting, tan-furnace, and general working sheds; or, if this be not wanted on the south side, that part of the wall may be devoted to the training of fruit-trees.

7347. A compost-ground for different sorts of earths, gravel, manure, and the rubbish-heaep.

7348. A rotting-ground for depositing tree-seeds, in layers of sand or ashes, in order to rot off their external coats, and promote the decay of nuts or other hard covers of seeds. (0;8;9.)

7349. A parterre for the culture and display of such of the border and florists' flowers as are grown in the nursery, and for a specimen of rock-work, a flower-stage, aquarium, apiary, and covered seat for visitors.

7350. The main area of the nursery should be laid out, as nearly as the circumstances will admit, in parallelograms, of any convenient dimensions, but not wider than the ordinary length of a garden-line, say under 150 feet, which allows of a row sufficiently long for any purpose. The chief reason for the parallelogram form is, that all rectangular figures are most easily cultivated and measured, and the reason for their being all of the same size is, in order that the master may readily, after a little experience, form a tolerably accurate idea of the quantity of every kind of nursery labor requisite for a plot of this shape and size. Thus, supposing each division to contain half an acre; then one man will dig it in one day, trench it in two days, hoe it, if in wide rows, in a fourth of a day, if in narrow rows, in half a day. A woman, if in beds, will weed it, if very thick of weeds, in two days; if thin of weeds, in one day, and so on. The compartments should, as much as possible, be cropped with one general class or kind, and by rotation. As, for example, for seven years: 1st, Break up from grass with turnips after trenching; 2d, Transplanted forest trees, two years; 3d, Green crop, one year; 4th, Annual flowers, for seed, one year; 5th, Seedlings, one year; 6th, Transplanted fruit-trees, four years; 7th, Bedded thorns, two years; and so on. Some compartments must be set apart for common stools; and if the circumferential borders are not sufficient or proper for stools of rare or peculiar sorts, others must be contrived by means of hedges, pales, or walls, to produce shelter and shade for cuttings, fit situations for bog-earth borders, American stools, bog plants in general, and similar purposes. If the borders are all of the same width, say ten or twelve feet, it will simplify all future calculations as in the compartments.

7351. A grand central, and a circumferential walk, with some cross walks, should be contrived to display the whole nursery to the best advantage. A narrow or common sized border should accompany these walks, excepting where the broad circumferential border comes in; and in the narrow borders should be displayed single specimens of all the more rare trees and shrubs grown either from seed, or by other means, for sale, and of all the perennial, biennial, and annual border-flowers sold to the public in the form of plants, roots, or seeds. Those may be excepted which are grown in the flower-garden, rock-work, and aquarium.

7352. A nursery-orchard should be formed of some compartments near the house; and in these, one or better two plants of each of all the hardy standard fruit-trees should be planted, in order to come into bearing, and admit of proving the kinds; and from which alone the grafts and buds should be taken, (unless on the introduction of new and valuable sorts, in which case such grafts as can be got must be taken till some of the progeny moved to the nursery-orchard come into a bearing state,) which are to be used in the nursery. This
orchard should be surrounded by a wall, on which to grow specimens of such sorts of plums, cherries, and pears, as do not ripen well as standards; the hardier sorts of grapes, and peaches, nectarines, and apricots. The tenderer sorts of vines, and some few peaches, which are tender in the northern counties, may be grown, one of a sort, under each rafter in the range of hot-houses.

7353. The compartments for stools of every description, and the borders for cuttings, should be as near the house as possible, as on these, men are employed a greater number of days in the year than on any other of the compartments, and therefore it is desirable such compartments should be more immediately under the eye of the master.

7354. Fruit-tree and seed-bed compartments should come next; then transplanted shrubs; next young forest trees transplanted; and, in the most distant parts, the larger forest trees, as requiring least culture of all. But a proper attention to rotation will not admit of this arrangement being completely attended to; and to keep the ground in good heart is as essential to success as keeping the men at work.

7355. In some of the principal nurseries which have risen to their present degree of eminence by degrees; and where consequently one building or additional object has been added to another as wanted, without having any general plan in view, the greatest confusion in appearance, and a considerable loss of labor, is the final result. The best way in such a case is to pull down great part of the hot-houses and outbuildings, and re-arrange the whole on some plan which will admit of a regular tour of inspection, either by the master or stranger-visitants. A fine example of this has recently been given by Messrs. Loddis; whose arrangements, and mode of displaying the whole to strangers, is so perfect, that the time saved in conducting visitors through the premises will be no small gain.

7356. The Hackney nursery (fig. 736.), or commercial botanic garden, affords an example of a small irregular spot, laid out both with due consideration as to effect, botanical science, and economy as to culture. The entrance (a) leads to the range of hot-houses, and continues with the stoves (b), proceeds to the green-house (c), thence to the dry-stove bulbs, and other articles (d), to the double camellia-house (e), and the green-house plants (f). The area enclosed by these buildings is devoted to the culture of plants in pits and frames, to beds of rare American and herbaceous plants, and to collections in pots ready for sale. The central space on the north side (g) is used as a depository for soils, pots, and other agents of culture; and for propagating-pits (h), and nursery-plantations of delicate articles. The visitant having arrived at the end of the artificial climates, next enters on the course of the arboretum (i, j, k), which is arranged alphabetically, and occupies one side of a winding walk, till it has passed through all the trees and shrubs, which will grow in the open air, with the exception of some of the more common species, of the roses, and American select shrubs. This walk crosses a public lane (l), on an elevated bridge, and entering an irregular piece of ground, winds round it till it terminates in an American ground in the centre (m), composed of a series of revolutions of grass-walks, with intervening beds of bog-earth, displaying a complete collection. The arboretum alphabet is only carried along the right hand of the arboretum walk (i, j, k), and on the left hand is a complete collection of roses for a certain length, and then herbaceous plants for the rest of the space. The beauty of this arrangement is, that there is no interruption to the series when once entered on, while at the same time any of the genera along the winding paths may be gone to at once by small paths, which occur here and there across the borders. A visitant wishing to see the American collection only, will proceed at once to its commencement (l), and wind along it till he arrives at its termination (m), and so on. The arboretum contains a number of species and varieties not before introduced, or hitherto neglected in this country. Every species commences with a named specimen, left to attain its natural size and shape next the walk; behind, in a line, are stools for laying or stocks for grafting, and the next two or three lines are devoted to the reception of the young plants till sold or disposed of. This mode saves much trouble in culture, and at once shows the purchase of the sort of tree he is to get, and assures him that he is getting its real progeny. The names of the trees and American shrubs, and the numbers of the herbaceous plants and roses, are painted on the ends of bricks, which are let half their length into the ground, in an oblique manner, so as their ends may meet the eye at a favorable angle.

7357. Of florists' gardens there are two sorts; the first for the purpose of forcing flowers in pots, for drawing-room gardens, and raising others in the open air for the flower-market; the second for the propagation and culture of florists' flowers, in order to vend their bulbs and plants. Both should be situated near a large town, as a market for the produce of the first kind; and to ensure visitors to the flower-shows of the second. A low situation, if possible near the sea, but at all events with a humid atmosphere, is to be preferred for the culture of bulbs; and no florists'
flower will thrive in an atmosphere impregnated with coal-smoke. Very little skill is requisite for laying out either of these gardens to those who understand the culture they require. The hot-house, pit, and frame departments should be kept together; close to them the compost, dung, and tan grounds or sheds; next the ground where pots of roses, &c. are plunged; and the least near parts remain to be devoted to the culture of flowers or flowering shrubs in the open ground. For the convenience both of culture, without treading on the plants, and of gathering the flowers, the whole is generally laid out in beds, sometimes with box-edgings, but more commonly without any, which for bulbs and plants to be annually removed, admits of more effectual culture.

7358. Market-gardens are of two kinds; those cultivated by manual labor, and those wholly or in part by the plough. In choosing a fit situation for a market-garden, regard must not only be had to the requisites for a good kitchen-garden, as to shelter, soil, water, &c. (2382. to 2430.), but to the probable market-kind of produce to be grown, &c. The extent must depend jointly on these circumstances and the capital to be employed. The smallest extent of surface and capital is that in which a man performs the whole of the labor himself, and this so entirely depends on the articles cultivated, the nature of the soil, and mode of culture, that it may vary from one to two acres, and where grain and seed crops are introduced, to a greater number. As to the quantity of ground which a man of capital may manage by this way, no limits can well be assigned to an active and vigilant master. Some London gardens of this description, entirely cultivated by manual labor, exceed 100 acres. In laying out a market-garden there cannot be said to be any thing peculiar: the general points of order, distinctness of compartments, and keeping the plots as much as possible in squares and parallelograms, are of obvious importance.

7359. Public orchards are of various kinds; garden-orchards, where the ground is cultivated and cropped with culinary vegetables or small fruits; arable orchards, where the trees are in rows, and the spaces between in aration; and pasture-orchards, where the trees are scattered over pasture-lands. In fixing on a situation for either kind, the three chief points are soil, sub-soil, and shelter, which have been already considered in treating on private orchards, as well as the planting and kinds of fruit-trees.

7360. Physic or herb-gardens, if for growing aquatic herbs, as mint, should be situated in a low moist soil; if for aromatic herbs, as lavender, rosemary, &c. on a dry poor soil; and if for roses and similar plants, for producing flower-leaves, for the distiller, the soil should be loamy and rich. In laying out this kind of garden, the only point in which skill is requisite, is the contrivance of a system of irrigation for the mints.

7361. Seed-gardens, or seed-farms, require a dry soil; and two should never be situated together, if destined for the same sorts of seeds. All the art in them consists in cropping, so as to ensure seeds true to their kind. Indeed, the culture is by far the most important consideration, not only in this, but in the four preceding descriptions of public gardens; and this is still more the case with respect to gardens for peculiar crops, as for the bulbs of white lily, rhubarb-roots, licorice, &c. which, as to laying out, require no further notice.

---

Of the Practitioners of Landscape-Gardening.

7362. The practice of landscape-gardening has been thought such a simple business, that every proprietor might perform it for himself. The same thing, indeed, may be said of the practice of medicine, law, or cookery, for every one can prescribe a cure, decide a quarrel, or boil an egg. "Had the art of laying out grounds," Repton observes, "still continued under the direction of working-gardeners or nurserymen, the proprietor might supersede the necessity of such landscape-gardeners, provided he had previously made this art his study; but not (as it is frequently asserted,) because the gentleman who constantly resides at his place must be a better judge of the means of improving it, than the professor, whose visits are only occasional; for if this reason for a preference were granted, we might with equal truth assert, that the constant companion of a sick man has an advantage over his physician. Improvements may be suggested by any one; but the professor only acquires a knowledge of effects before they are produced, and a facility in producing them by various methods, expedients, and resources, the result of study, observation, and experience. He knows what can and what cannot be accomplished within certain limits. He ought to know what to adopt, and what to reject; he must endeavor to accommodate his plans to the wishes of the person who consults him, although in some cases they may not strictly accord with his own taste." (Observ. on Landsc.
Gard. p. 10.) A more wise plan than that of doubting on the subject would be to have the separate opinions of different landscape-gardeners and architects; for no opinion need be followed if disapproved of; while the probability is, that there would be something valuable in each, and the proprietor might finally, aided by the artist he preferred, decide for himself, never, however, forgetting the idea of a consistent and beautiful whole. As to the expense of opinions, Girardin observes on this subject, "N'allez pas le regarde—il vous en coûtera bien davantage pour des variations, et des retouches continues."

7363. The intimate connection between landscape-gardening and architecture; the propriety and advantage of the joint consultations of the landscape-gardener and the architect, as to the situation, aspect, and style of the house; together with the almost unavoidable encroachments of the former on the latter, by designing and executing garden-buildings, has given rise to an opinion, that the landscape-gardener ought to combine the functions of the architect. Repton justifies the idea, by referring to the many excellent houses built by Brown, with no other knowledge than that acquired by observation of all the best houses; and of Kent, who was at once landscape-gardener, architect, and historical painter. We are of opinion, that in the case of garden-buildings and small villas, or ornamented cottages, the knowledge both of the theory and practice of architecture, which it is necessary every landscape-gardener should possess, may sometimes enable him to combine the duties of both professions; but such are the advantages of a division of labor in the fine, as well as in the useful arts, that in all more extensive buildings, and indeed even in those we have mentioned, we would recommend the employment of a regular architect, jointly with a landscape-gardener, as a surgeon consults with a physician in important cases. — The duties of the landscape-gardener resolve themselves into the formation of a plan or design, and the carrying of it into execution.

Sect. I. Of the Study of the given Situation and Circumstances, and the Formation of a Plan of Improvement.

7364. Whatever may be the situation and circumstances where the opinion of a landscape-gardener is desired, he should be furnished with a written or verbal instruction as to the points to which he should chiefly direct his attention; with a complete map of the estate, and an accurate detailed history and description of its localities and peculiarities. From these, from topographical and county surveys, and a residence of a few days or weeks, according to the extent of the subject and season of the year, (spring, before the leaves expand, being the most favorable time,) he will be able to procure every requisite information, and to establish in his memory every thing relating to the situation and vicinity. He is then, and not before, to embody and mature his ideas of improvement; directing his attention first to the situation and aspect of the house and offices, the extent of the park, and the emplacement of the kitchen-garden; next to the general masses of wood; and then, successively, to the breadth of lawn, the situation and character of water, the pleasure-ground, farm, and other details. Before making up his mind on any part of the subject, he will often find it of importance to have sections taken of the grounds in different directions, levels of springs, and rills, &c.; and most frequently he will have occasion for stakes, for marking out lines on the ground; of flagstaffs or poles, from six to fifty feet high, to represent the effect of trees (fig. 737.) and other objects; of strips of white sheeting, to show the effect of water, by forming a white outline on a perfect level; of frames partially covered with boards, to show the effect of buildings; and he may even require boring-irons, or pits dug, in order to enquire into the nature of the subsoil. Being furnished with a plan of the present state of the grounds, (such as fig. 351.) he will, as he makes up his mind on particular improvements, mark them down on this map in pencil, and when the whole is finally adjusted, he will put them in red, or in any distinguishing color. And on one or more general or panoramic views (fig. 355.), as well as on the particular views which he may have taken on different spots, he will also mark
in red the outlines that will be made by the improvements adapted to the different situations. In addition to these, he will show the effect, by geometrical sections taken in different directions across the grounds (fig. 349.), to show the ground’s surface. His next operation is to make a vertical profile (figs. 353, 354.), showing the effect of the whole, supposing the alterations to be fifteen or twenty years completed, with corresponding, panoramic, or general views (fig. 355.), and with particular landscapes.

7365. It remains for him to give reasons in writing for all that he proposes; a practice which no employer or artist should ever omit to have done, as such opinions remain as data, to be referred to concerning the management and future effects; as well as in point of present or future justification of the taste, both of the artist and proprietor. This may be done in the following order: 1. Recapitulating the given instructions; 2. The characteristic features, and other details, of the given situation and vicinage; 3. A description of, with the reasons for, the general outline of improvement; 4. The description of, with the reasons for the detail; 5. An outline of the future management; 6. Directions for the execution; and, 7. An estimate of the expense.

7366. In all these discussions proper references will be made to the maps and sketches. Simple language will of course be employed in describing future effects; but, above all, simple sketches, which shall owe little of their effect to shading, and none to coloring, or finishing, are essentially necessary.

7367. Girardin seems to have been the first who suggested this mode of obtaining an opinion systematically; and his remarks on the fallacious effect of beautiful drawings instead of outlines, are well deserving of attention. "Vous fâcherez même que cette esquisse ne soit qu’un simple trait, et ne présente d’abord que les formes principales des objets, et la disposition générale des grandes masses de votre ensemble. Un dessin bien fini ne manquera pas de vous échauffer par l’agrément de la touche d’un habile artiste; vous vous déterminerez d’après un dessin dont vous ne réussiriez peut-être pas à obtenir l’effet dans la nature, et il faut bien mieux avoir à gagner qu’a perdre dans l’exécution." 7368. Repton has the merit of first employing this system elegantly and extensively in England, and of adopting, instead of one entire landscape to show the previous taste, and another to show the effect of the alterations, a slip of paper of the size and shape of those parts of the landscape which require alteration. This is fixed at one edge of the entire landscape, and lies flat over part of it, so that when lifted up it shows the full effect. It must be confessed, however, that, though an elegant mode, it is not perfectly fair, since the view in which the cut paper forms a part can never look so well as the other, even from the mere circumstance of the bounding line of the paper. For some cases, however, it may be used, though in general it will be found, that two entire landscapes afford the most impartial means of judging of the effects of an improvement. The discussion and sketches of the place, and improvements being finished, and bound in a book, the ground or working plan is to be put on canvass, or copied on parchment paper, one copy for the gardeners, or whoever sets out the work; and the profile put on rollers, to be preserved along with the book of notitia. These being delivered to the proprietor, he will determine, after mature deliberation, whether or not he will adopt the whole, or any part of the improvements, previously consulting those friends whose taste or judgment he considers adequate to forming a judicious opinion on the whole, or any one part of the subject. "Lorsqu’il esquisse de votre ensemble sera fait, alors vous réfléchirez, vous concerterez avec des gens de goût, l’ordonnance générale de la disposition qu’elle vous présente."

In this example of forming a plan, we have had in view a dull and nearly flat site, where nothing has been done; but it is evident that the same general principles are applicable to such places as are to be altered, diminished, or enlarged.

7369. By a general plan, accompanied by others more detailed, of the kitchen-garden, pleasure-grounds, terrace, &c. and by the explanatory details of the book of notitia, any gardener of ordinary intelligence may execute the most intricate design, and if this design has been carefully formed from inspecting the premises, and proper general views have been minutely taken from different points, the landscape-gardener may show the effect of future improvements with confidence, and leave behind him the Notitia, or Book of Improvements, or, in other words, such plans, sections, views, and written instructions, as may enable the gardener gradually to produce them, with nearly as much certainty as an architect directs a builder to raise an elevation of masonry. Distinctly situated proprietors, ambitious of displaying some refinement of ideas on rural matters, might in this way first procure, and then work to a general plan; instead, as is often the case at present, of working according to their own crude notions; and producing scenes which afford no pleasure to any one but their owner, and only to him whilst he remains in statu quo as to taste.

SECT. II. Of carrying a Plan into Execution.

7370. Whether a plan be carried into execution by contractors, or by the proprietor at his own risk, must depend on circumstances, both respecting the knowledge, taste, and leisure of the proprietor, and the nature and extent of the improvements. Where an entire new house and grounds are to be created, an eminent substantial contractor for the buildings, and another for the ground operations, will be found the most speedy and certain as to expense; the work, in both cases, being liable to be regularly examined at stated periods by a neutral surveyor, accompanied by the original designers of the improvements. If this mode is not adopted, the whole or greater part may be done under the eye of the owner and his steward; various, and as many parts as possible, being let by the job. We shall take a cursory view of the chief objects of alteration or addition; and indicate some things in each, which may in most cases be more profitably done by the job, premising, that whenever the cost or intricacy of any piece of work is consider-
able, unless a contractor of some respectability is employed, the work is much better done by the laborers of the proprietor.

7371. Buildings. All alterations or new erections may be readily estimated and executed by contract, and, almost in every case, at less expense to the proprietor. The mere difference between the trade price and the gentleman’s price of the materials and labor, and between the hours kept, and quantity of work done in a given time by a journeyman to a master-tradesman and to a gentleman, will (if the former should, by error in estimating, find no other gain), afford a certain profit to the tradesman; and thus, suppose a contractor to estimate a piece of work at 1000l., and which the proprietor, changing his mind, instead of letting to the contractor, executes himself, and finds the amount 1100l., the contractor, had he got the job, would have actually had a profit, and the owner been a gainer of 100l. The mansion, domestic and farming offices, garden-walls, and hot-houses, may all be separately contracted for.

7372. Ground. The removal of ground, fences, or digging, may in every case be let by the job, and with decided advantage to both parties. The extent of particular contracts should, of course, be in proportion to the responsibility of the contracting parties.

7373. Planting. The enclosures and the preparation of the soil may, in all extensive cases, be executed by contract; but the planting or insertion of the plants, on which so much depends, should uniformly be done by day-work; excepting, however, those cases in which a respectable nurseryman will engage to put in a certain number of plants of a certain kind, size, and age, and maintain them there for at least three years. In some extensive cases, the land may be prepared by fallowing, which the adjoining farmers will generally undertake at a very moderate price per acre. In most cases, the contractor for fences, of whatever description, should undertake to uphold them for a given number of years; and in cases of thorn-hedges, or other live fences, until they become sufficient barriers.

7374. Road and walk making may frequently be contracted for; but in this case, as in every other, much will depend on the skill, activity, and experience of the gardener or general overseer. This subject will be found illustrated at greater length, and in a manner incompatible with the nature of this work, in the second edition of our Treatise on Country-Residences, 4to.

---

PART IV.

STATISTICS OF BRITISH GARDENING.

7375. After having considered gardening as to its history, as to the scientific principles on which it is founded, and the application of these principles to the different branches of practice; it remains only to take a statistical survey and estimate of its present state and future progress in the British isles.

---

BOOK I.

OF THE PRESENT STATE OF GARDENING IN THE BRITISH ISLES.

7376. The present state of British gardening, as to knowledge, has been the subject of the former parts of this work; but its importance, in the general economy of society, can only be learned by a statement of the manner in which it is actually carried on; the modifications to which it has given rise in the pursuits of those who have embraced the art as a source of livelihood; of the kinds of gardens employed by men of different orders in the state; of the principal gardens as distributed in the different counties of Britain and Ireland; of the British authors who have written on gardening, and of the private or professional police, and public laws relative to gardeners and gardens.
Chap. I.

Of the different Conditions of Men engaged in the Practice or Pursuit of Gardening.

7377. Gardeners may be arranged as operators or serving gardeners; dealers in gardening or garden-tradesmen; counsellors, professors, or artists; and patrons.

Sect. I. Of Operators, or Serving Gardeners.

7378. The garden-laborer is the lowest grade in the scale of serving gardeners. He is occasionally employed to perform the common labors of gardening, as trenching, digging, hoeing, weeding, &c. Men for the more heavy, and women for the lighter employments. Garden-laborers are not supposed to have received any professional instruction, farther than what they may have obtained by voluntary or casual observation. In all gardens where three or four professional hands are constantly employed, some laborers are required at extraordinary seasons.

7379. Apprentice. Youths intended for serving, or tradesmen-gardeners, are generally articled or placed under master or tradesmen gardeners, for a given period, on terms of mutual benefit: the master contracting to supply instruction, and generally food and lodging, or a weekly sum as an equivalent; and the parents of the apprentice granting the services of the latter during his apprenticeship as their part of the contract. The term agreed on is generally three years; or more if the youth is under sixteen years of age but whatever may be the period, by the laws as to apprentices it must not extend beyond that at which the youth attains the age of manhood. No one can ever expect to attain to the rank either of master-gardener or tradesman, who has not served an apprenticeship to the one or the other. In general it is preferable to apprentice youths to master-gardeners, as the labor is less than in tradesmen's gardens, and the opportunities of instruction generally much greater.

7380. Journeyman. The period of apprenticeship being finished, that of journeyman commences, and continues, or ought to continue till the man is at least twenty-five years of age. During this period, he ought not to remain above one year in any one situation; thus, supposing he has completed his apprenticeship in a private garden at the age of twenty-one, and that his ultimate object is to become a head-gardener, he ought first to engage himself a year in a public botanic garden; the next year in a public nursery; that following, he should again enter a private garden, and continue making yearly changes in the most eminent of this class of gardens, till he meets with a situation as head-gardener. The course to be followed by an apprentice intended for a tradesman-gardener is obvious; having finished his period in a private garden, let him pass through a botanic and nursery-garden, and then continue in the most eminent of the class of public or tradesmen's gardens, to which he is destined.

7381. Foreman (before-man, or first man). In extensive gardens where a number of hands are employed, they are commonly grouped or arranged in divisions, and one of the journeymen of longest standing employed as foreman or sub-master to the rest. Whenever three or more journeymen are employed, there is commonly a foreman, who has a certain extent of authority at all times, but especially in the absence of the master. This confers a certain degree of rank for the time being, but none afterwards.

7382. Master-gardener. A journeyman has attained the situation of master-gardener, when he is appointed to the management of a garden, even if he has no laborer, apprentice, or journeyman under him; but he has not attained to the rank of master-gardener till having been a year in such situation. Afterwards should he be obliged to work as journeyman, he still retains the rank and title of master-gardener but not of head-gardener.

7383. A head gardener, or upper gardener, is a master who has apprentices or journeymen employed under him. Out of place and working as a journeyman, he retains the rank and title of master-gardener, but not of head-gardener.

7384. Nursery-foreman. This is an important situation, the foreman being entrusted with the numbered and priced catalogues of the articles dealt in; authorised to make sales; entrusted to keep an account of men's time, &c. (see Time-Book, 238.) and in consequence it entitles the holder to the rank of head-gardener while so engaged, and to that of master-gardener ever afterwards; the same may be said of foremen to public botanic gardens, and royal or national gardens.

7385. A travelling gardener is one sent out as gardener, or collector of plants, along with scientific expeditions; he is generally chosen from a botanic garden; and his business is to collect gardening productions of every kind, and to mark the soil, aspect, climate, &c., to which they have been habituated.

7386. Botanic curator. This is the highest situation to which a serving gardener can attain next to that of being the royal or government gardener. He superintends the culture and management of a public botanic garden; maintains an extensive correspondence
with other botanic curators; exchanges plants, seeds, and dried specimens, so as to keep up or increase his own collection of living plants, and herbarium siccum. Abroad, for want of sufficiently intelligent practical gardeners, they have what are called directors and inspectors of botanic or other government gardens; but no such office is requisite in this country.

7387. Royal gardener, court-gardener, or government-gardener; Jardinier de la Cour, Fr.; Hoffgarten, Germ.; and Giardiniere della Corte, Ital. This is the highest step, the summum bonum of garden-servitude. In foreign countries, the court-gardener wears an appropriate livery, as did formerly the head gardeners of the principal nobility, as well as the court-gardeners of this country. At present this remnant of feudal slavery is laid aside in every grade of British garden-servitude.

Sect. II. Tradesmen-Gardeners.

7388. Of tradesmen-gardeners, the first grade is the jobbing gardener, who makes and mends gardens, and keeps them in repair by the month or year. Generally he uses his own tools, in which he is distinguished from the serving gardener; and sometimes he supplies plants from a small sale-garden of his own.

7389. Contracting gardeners, or new-ground workmen, are jobbers on a larger scale. They undertake extensive works, as forming plantations, pieces of water, roads, kitchen-gardens, and even hot-houses, and other garden structures and buildings. Formerly, and especially in Brown’s time, this branch of trade was combined with that of the artist-gardener, but now since the principle of the division of labor has been so much refined on, they are generally separated.

7390. Seed-growers are as frequently farmers as gardeners; their gardens or fields are situated in warm districts, and they contract with seed-merchants to supply certain seeds at certain rates, or to raise or grow seeds furnished to them by the seedsmen on stipulated terms. The great test of excellence here is never to grow at the same time such seeds as may hybridise the progeny by impregnation.

7391. Seed-merchants, or seedsmen, deal in garden-seeds and other garden-productions; in general they combine the business of nurseriesmen or florists, but sometimes confine themselves entirely to dealing in seeds wholesale, or to a sort of agency between the seed-growers and the nursery-seedsmen.

7392. Herb-gardeners grow herbs, either the entire herb, as mint, or particular parts, as the bulb of lilium, and the flower of the rose for medical purposes, or for distillation or perfumery.

7393. Physic-gardeners, herbalists, or simplicists, not only grow herbs for the purposes of medicine, or perfumery, but collect wild plants for these purposes. Formerly, when it was the fashion among medical men to use indigenous plants as drugs, this was a more common and important branch of trade. They have commonly shops appended to their gardens, or in towns, in which the herbs are preserved, and sold in a dried state.

7394. Collectors for gardens. The first variety of this species is the gipsy-gardeners, who collect haws, acorns, and other berries and nuts, and sell them to the seedsmen; the next are those who collect pine and fir cones, alder-catkins, and other tree-seeds, which require some time, and a process to separate the seeds from their covers, and clean them before they can be sold; and the highest variety are those gardeners who establish themselves in foreign countries, and there collect seeds and roots, and prepare dried specimens of rare plants for sale.

7395. Orchardists of the simplest kind are such as occupy grass-orchards, where the produce is chiefly apples, pears, and plums, for cider or kitchen-use; the next variety occupy cultivated orchard-grounds where fruit-shrubs, as the gooseberry, currant, strawberry, &c. are grown between the fruit-trees; and the highest variety occupy orchards with walls and hot-houses, and produce the finer stone-fruits and forced articles.

7396. Market-gardeners grow culinary vegetables and also fruits; the simplest kind are those who grow only the more common hardy articles for the kitchen, as cabbage, pease, turnips, &c.; a higher variety grow plants for propagation, as cauliflowers, celery, and artichoke-plants, and pot-herbs, as mint, thyme, &c.; and the highest variety possess hot-beds and hot-houses, and produce mushrooms, melons, pines, and other forced articles and exotic fruits. They have often shops at their gardens, or in towns, for the disposal of their produce; and these, when fruit is chiefly dealt in, are called fruit-shops; where culinary vegetables are joined, green-grocery shops. Most commonly, however, the culinary vegetables are carried to market, and there disposed of to such as retail them in shops or on stalls. Occasionally they are deposited for sale in the hands of agents or brokers, and sometimes shops are supplied regularly on certain conditions.

7397. Florists are either market-florists who grow and force flowers for the market, and of this subspecies are two varieties, those who grow only hardy flowers to be cut as nose-
gays, and those who deal chiefly in exotics or green-house plants to be sold in pots. The other subspecies is the select florist, who confines himself to the culture of bulbous-rooted and other select or florists' flowers, who has annual flower-shows, and who disposes of the plants, bulbs, tubers, or seeds.

7398. Botanic gardeners are such as devote themselves exclusively to the culture of an extensive collection of species for sale; these may be either limited to indigenous kinds, as was the botanic garden of the late Don of Forfar, embracing all hardy plants, or extending to tender exotics. Botanic gardeners also collect and dry specimens of plants, and also of mosses, fungi, algae, &c. for sale: to this they often join the collecting of insects, birds, and other animals.

7399. Nursery-gardeners, or nurserymen. This is the highest species of tradesman-gardener. Their business is to originate from seed, or by other modes of propagation, every species of vegetable, hardy or exotic, grown in gardens, to rear and train them for sale, and to pack or encase them, so as they may be sent with safety to distant places. The nurseryman is commonly also to a certain extent a seed-grower, and is generally a seed-merchant, supplying his customers annually with what seeds they require for cropping their gardens as well as with the trees they use in stocking them. The simplest variety of nursery-gardener is he who confines himself to the rearing of hedge plants and forest trees; the highest, he who in addition to all the hardy trees and plants maintains at the same time a collection of tender exotics.

Sect. III. Garden Counsellors, Artists, or Professors.

7400. The first species of this genus of gardeners, is the garden surveyor, or valuator. His business is to estimate the value of garden labor and produce, and of garden structures, edifices, and gardens themselves. When a proprietor lets his house and garden to a tenant for a certain number of years, the stock of the garden is valued, and either entirely paid for by the tenant, or it is again valued when the latter quits the premises, and the difference in value paid either by the tenant to the landlord, or by the latter to the former, as the case may be. It is the business of the garden-surveyor to estimate the value of the stock, crop, and business of nurserymen, and other tradesmen-gardeners, quitting or entering on premises, or purchasing or disposing of their establishments. The garden-surveyor is sometimes also a garden-auctioneer; but generally his business is confined to valuing, and practised by nurserymen or other tradesmen-gardeners.

7401. The tree-surveyor, or timber-surveyor, limits his occupation to arboriculture: he measures and values standing timber or copsewood; estimates the value of young plantations, the expense of forming them, of managing them during a certain number of years; of enclosing with live hedges of every kind, and their management till fence high: he determines what trees shall be felled, thinned, or pruned, and directs the manner of performing these operations.

7402. The horticultural architect (Planner, Scotch) gives designs for kitchen-gardens and flower-gardens, with their structures and buildings: he sometimes also lays out shrubberies and pleasure-grounds, when on a small scale. In this case he takes the title of ornamental gardener (Planner of policies, Scotch), or ground-architect.

7403. The horticultural artist is employed in designing and painting fruits, flowers, plants, implements, and horticultural structures and gardens, but chiefly in drawing fruits and flowers, the gardens and structures being more commonly drawn by the horticultural architect, or landscape-gardener.

7404. The landscape-gardener, or layer out of grounds; Artiste jardiniier, Ingénieur des jardins pittoresques, ou Anglais, and Jardinier paysagiste, Fr.; Garten künstler, Ger.; and Artiste giardinieri, Ital. This species of counsellor gives designs for disposing of the plantations, water, buildings, and other scenery, in parks or landscape-gardens, and generally for every thing relating to the arrangement of a country-seat, excepting the architecture of the mansion, offices, and other buildings; but in what respects the site of these, and the exposure of the principal fronts and apartments of the house, his counsel is required jointly with that of the architect.

7405. The gardening author may be considered the most universal kind of garden-counsellor, since his province extends to every branch of the art. The simplest variety of this species is the author of remarks, or an essay, or treatise on one particular plant or subject; the most comprehensive, he who embraces the whole of the science and art of gardening; but the most valuable, he who communicates original information.

Sect. IV. Patrons of Gardening.

7406. Every man who does not limit the vegetable parts of his dinner to bread and potatoes, is a patron of gardening, by creating a demand for its productions. He is a consumer, which is the first species of patron, and the more valuable varieties are such as regularly produce a dessert after dinner, and maintain throughout the year beautiful nosegays and pots of flowers in their lobbies and drawingrooms.
7407. **Amateurs** (lovers of gardening). These promote the art by the applause they bestow on its productions, of which, to a certain extent, they become purchasers.

7408. **Connoisseurs** (critical or skilful lovers of gardening). These promote the art in the same way as the amateur; but much more powerfully, in proportion as approbation, founded on knowledge, is valued before that which arises chiefly from spontaneous affection. By the purchase of books, engravings, and drawings, from which, in great part, this species of patrons acquire their knowledge, they may be said to be eminent encouragers of counsellor-gardeners.

7409. Employers of gardeners, whether of the serving, tradesman, or counsellor classes, are obvious and undoubted patrons of the art.

7410. **Occupiers of gardens** of necessity employ both serving and tradesmen gardeners, and when they are amateurs or connoisseurs, are often great encouragers of the art; for every one is not so fortunate as to rank among the

7411. **Proprietors of gardens** who are the most eminent of all patrons, promoting every department of the art, and employing serving, tradesmen, and artist gardeners. A man whose garden is his own for ever, or for a considerable length of time, whether that garden be surrounded by a fence of a few hundred feet, or a park-wall of ten or twelve miles, will always be effecting some change in arrangement, or in culture, favorable to trade and to artists.

"I pity that man," says Pope, "who has completed every thing in his garden." "Après mes enfants et deux ou trois femmes que j’aime, on crois aimer à la folie, mes jardins sont ce qui me fait le plus de plaisir au monde; il y en a peu d’aussi beaux." (Mémoires et Lettres du Prince de Ligne, tom. i. 117.)

** Chap. II. 

Of the different Kinds of Gardens in Britain, relatively to the different Classes of Society, and the different Species of Gardeners.

7412. In order to form an estimate of the importance of gardening to a people, and of the duties of gardeners in filling different situations, it is not only necessary to notice the different species of gardeners to which it has given rise, but also the different kinds of gardens; the classes of society which enjoy them; and the species of operators and patrons who cultivate and encourage them. In this view, gardeners may be arranged as private, commercial, or public establishments.

**Sect. I.** Private British Gardens.

7413. Of **private British gardens**, the most numerous class of gardens, and those the most regularly distributed over the British isles, are those of the country laborer, or what are usually denominated **cottage-gardens**. Next to his cottage, the laborer finds his garden the most useful and agreeable object, by supplying a part of his food, affording an agreeable source of recreation, and presenting an opportunity of displaying his taste in its cultivation. To the laborer who has no cottage or garden, human life presents no hopes; his future extends only to a few days; he has no consolation but in the contemplation of fixed wages, which the most fatiguing exertions can in no degree increase, and of which, in the case of illness, he has only the amount of a week to interpose between the absolute want of lodging and food. But the laborer who rents a cottage and garden is secure at all events of a roof to cover him; he can multiply his pleasures and pains by the addition of a wife and children; and he knows that he can live for a certain time on the produce of his garden. By these hopes he is consoled. Besides, he has that most desirable object, something that he can call his own; and is thus enabled to participate in the feelings which belong to the love of property and progeny—feelings often, indeed, mixed with pain, but which nevertheless, have been an object of ambition from the earliest ages of the world.

7414. **Cottage-gardens**, in a moral and political point of view, are of obvious importance; attaching thecottager to his home and to his country, by inducing sober, industrious, and domestic habits; and by creating that feeling of independence which is the best security against pauperism.

7415. The extent of the garden of a laborer ought never to be such as to interfere with his employment as a laborer; unless it is sufficiently so to enable him to dispose of part of the produce in the manner of a market-gardener, or to keep a cow and dispose of her produce. But as it will rarely happen that in either case he can compete in the market with the regular market-gardener or farmer, the most useful extent of garden is that which shall occupy his own leisure hours in the operations of digging and planting, and those of his wife and children in hoeing, weeding, and watering. This will generally, as already stated (7396), be something between one eighth, and three sixteenths of an acre, including the space on which the cottage stands.

7416. The **vegetables** which may be most profitably cultivated by the occupants of this description are, cabbages of the early heading sorts, hardy borecole, as the German greens, early potatoes, parsnips, tur-
nips, carrots, onions, leeks, peas, beans, and kidneybeans; a plant or two of celery (not to be blanched), thyme, mint, and chives for seasoning; and a few plants of rhubarb for tarts.

4717. The fruit-shrubs, which ought never to be omitted, are the gooseberry and red and black currant, as standards, in the margins of the plots, or against the walls or pales, if the garden is surrounded by these; the kinds of gooseberry should, for which as for the red currant are the Warrington reds, the amber, yellow globe, rough green, and crystal. The fruit-shrubs should be the best bearers among the baking apples and plums; as the hawthornean, and any of the cooling apples for early use, the grey russet and winter pearmain for winter and spring; and the damson, bullace, and the one-man-high, and any dwarf pear, or yair, or yarlot, pears. If the climate and aspect is favorable, the most southerly sides of the house may be covered with a white muscadin, or black July grape, or otherwise with pears in the best aspects, currants in the worst, and a rose and honeysuckle on the porch. (See 7310.)

4718. In the management of cottage-gardens, no opportunity should be neglected by the cottager of collecting manure from the highways, from the grass, weeds, and mud of ditches and lanes; leaves of trees, soot-ashes, and all household refuse, should be collected, and the whole mixed together in the dunghill (1977.), and turned frequently over before using. In the culture of these gardens, the principle of a change of surface (2549.), and of a rotation of crops (2556.), should be attended to; and also that of continually stirring the soil among growing plants as deep as possible; of watering in dry weather, regularly every evening, and of gathering by hand all worms, snails, slugs, grubs, and other insects, as soon as they appear. Of potatoes only the early sorts should be cultivated in the cottage-garden, because that plant is now so generally a subject of field-culture, that for a main supply the cottager will find it cheaper to purchase from the farmer; or to rent a few square yards of a field devoted to drilled green crops, and cultivate himself as many as may serve his family and his pigs and poultry. Besides, in either of these ways, he is more certain of obtaining potatoes of good quality, as even though the sorts be changed, still the quality is much deteriorated by repeated culture on the same spot.

4719. Improvement of cottage-gardens. It would be a most desirable circumstance, if proprietors who keep head gardeners would desire them to attend to the gardens of the cottagers on their estates; to supply them with proper seeds and plants; to propagate for them a few fruit-trees, and distribute them in the proper places in their plots; to teach them modes of culture suitable for their circumstances; and to enforce by adequate motives of hope or fear, of reward or removal, as the case might require. In this way, at no additional expense whatever to the proprietor, much happiness might be diffused; and constantly recurring objects too often indicating wretchedness, or at least slovenliness, rendered useful, neat, and even ornamental.

4720. Domestic improvement of cottagers. It would also be a very desirable circumstance if some of the female servants, or even some of the charitably disposed female members of the family, would instruct the cottagers' wives on their estates in improved modes of cookery, washing, making, and mending. It is astonishing how ignorant and how extravagant the humblest classes are in these respects; it is rare to find in operation any principle of action, or much regard to economy in domestic management. It appears to be all work at random, from the making of soup to the baking of pastry. Much might be done by taking any one cottage's dish, and cooking it in different ways before her. For example, soup from vegetables, water, and a little butter only. How different that made by merely boiling the ingredients and allowing them to simmer, by burning a part of the butter, adding toasted crumbs of bread, a few leaves of chives, and half a leaflet of green celery! How few cottagers know how to make the most of their bees, which besides honey, afford a most refreshing and enlivening drink, little inferior, when properly made, to champagne in its best condition. In the conduct of a day-laborer, is such a carelessness in procuring the raw materials of subsistence, that he is without leisure to invent the machinery, or resort to the manipulations necessary for manufacturing them into the best fabrics. But let him once be properly instructed in this matter; let him once feel the enjoyments of which, even his condition of life is susceptible, and he will not easily afterwards relinquish the circumstance. In a statute requiring the laborer to be more stupid, that almost every degree of refinement, or sensation beyond that of mere animal feeling, is lost on him. The rich man is happily willing to put his hand in his pocket to help him; but that merely affords a temporary relief from evil. To supply instruction in plain practicable economy, and to follow it up till it becomes a habit in the individual, is to effect a radical improvement in this condition of life; which will be felt by the subjects of it during their lives; and being transferred to their posterity like other habits and customs, must ultimately ameliorate this most numerous and efficient order of society.

4721. Supplying economical knowledge to cottagers. Something in furtherance of the above ideas might be done by distributing tracts on cottage gardening and house-economy; but man, grown up in ignorance without the habit of reading, does not readily receive instruction from books. His want of experience in book-knowledge prevents him from discerning what is practicable from what is speculative, and consequently to profit both with his labor and his leisure. It appears he needs to be instructed, and appropriate it to his use. The mind requires a certain preparation before it will receive new ideas; and its faculties must have been exercised on ordinary matters, before reason can be properly employed, on any subject not common. Tracts, therefore, among the laboring-classes are chiefly useful, in their elementary form, to explain the practice of their usual occupation, the common labors of the most common occupations of the common economy at school, which they might easily be by the Lancastrian method of instruction, it would fit them for entering on a life of labor with superior advantages, both in point of performing their labor, and in making the most of its reward.

4722. The cottage-gardens of artificers, that is, of operative mechanics and manufacturers, small tradesmen, and other country artisans, differ from those of the common laborer in being somewhat larger, and in having a larger portion of the space devoted to the culture of fruit-trees and flowers. They are cultivated by the occupier and his family, and very frequently sufficient ground is connected with these gardens to enable the occupier to keep a cow or horse. These indeed are often half-starved animals, producing little benefit to their owners beyond the feelings of satisfaction which the idea of possessing them confers. In several parts, and especially the north of England, and generally in Scotland, the gardens of artisans differ from those of the cottager, in being held on a
long building-lease, and in being situated in or around large towns. The most remarkable gardens of this description for riches, order, and beauty, are at Norwich, where they first originated (373.); at Spitalfields, near London, among the residences of the silk weavers; at Manchester, and other Lancashire and Cheshire towns; and at Paisley and Glasgow. The occupiers are generally their own masters, having their looms or other implements of trade within their dwellings, and being employed by manufacturer, or taking their goods to a common market. They are generally an intelligent, industrious class of men, who take great delight in their gardens, and the point of practice in which they excel is in the production of florists' flowers. Norwich is, or used to be, noted for carnations. Spitalfields is still noted for all the competition flowers, but especially for auriculas and tulips; Manchester for auriculas and polyanthuses, and also for the production of new varieties, and large specimens of gooseberries; and Paisley and Glasgow for pinks. The florists in Lancashire, indeed, excel in every branch of their profession, and are also famous for their success in cultivating the potato, which was in general use in this county long before it was known in many others. The artisans of Paisley are, perhaps, the most intelligent of their order in the world; even the speeches of what were called the radical reformers of this town, astonished by their argument and style; and the success of the florists, and the laws of their association, are not less surprising. (See Lancashire and Renfrewshire, in the succeeding chapter.)

7423. The farmer's garden (7293.) varies in extent from an eighth part to a whole acre or upwards, according to the kind of farm. Lord Kames (Gent. Farm. 297.) considers a fruitful kitchen-garden as the chief accommodation of a farm; yet farmers in general pay very little attention to their gardens, even where the best systems of agriculture are preserved. They are managed in the smallest farms by the farmer himself, with the occasional assistance of his men, and of the female part of his family; in those of a higher kind, where the farmer is not personally an operator, they are managed by a laborer, who is generally kept on the farm for cleaning hedges, clearing out furrows, and doing such extra field-work as cannot be performed by the regular hands of the farm.

7424. In tradesmen's farms, large, or what are called gentlemen's farms, villa farms, and fermes ormed the gardens are commonly managed by a gardener, who is expected to assist in the field during the hay and corn harvests; and, therefore, he seldom ranks high in his profession.

7425. The products of common farmers' gardens are of the most useful and handy kinds; but those of villa and ornamental farms contain hot-houses, and often produce many of the luxuries of regular farm or market gardening. In general, the gardens of the latter kind, excepting landed proprietors, have an opportunity of indulging their taste so variously and extensively, and at so little expense. In the first place, suppose a farmer to have a lease for twenty-one years, at a fair rent; whatever state he finds the farm in; if it be enclosed and subdivided, he may render it a farm garden, by leaving strips of pasture around all the arable fields, and connecting these by gates in such a way as that he may form a drive or riding (7280.) round and through the whole. Secondly, he may form, or enlarge and arrange, the kitchen-garden, flower-garden, orchard, and the portion of lawn and pleasure-ground round or beside the farm-house, at pleasure. Thirdly, he may heat hot-houses, pits, and hot-beds, at the expense of labor only, by fermenting his farmyard-dung in such pits as West's (fig. 250), in such venneries as Anderson's (fig. 461), or in other venneries for pines (fig. 462). or behind walls or pales, to force fruit-trees. Perhaps one of the simplest modes for a farmer to take the benefit of his fermenting farm, would be, to have a line of pales to serve as a wall for training on, hinged at the surface of the ground. These, when placed in a position forming an angle with the ground of 45°, the trees should be trained. Then, when the dung is to be placed behind, the pales should be elevated to the perpendicular, and the dung thrown down on a regular ridge, and a roll of dung towards the ridge in the middle of the ridge, or 45° in the north side. This being formed, the pales should be folded back on the slope, and the advantage of this plan over that of fixed upright pales would be, that as the dung sunk the pales would sink with it, and by being always in the same heat, would receive the usual heat and moisture, which, with the dung such as it, separates from the pales, and then the whole surface of the dung being exposed, the heat ascends, and is lost. But an exceeding good plan for every description of forcing or exotic culture, would be to construct houses on the plan of West's pit, with all that part of the north wall under the level of the north or floor for the pots substituted by cast-iron or stone pillars, and wooden gates between these. These would facilitate the putting in and taking out of the dung, and, being shut close, no part of the heat would escape. These plans are only for amateur, or proprietor farmers, for the common commercial or market farmer, who do not devote all the capital or attention to the subject. He, in general, leaves the care of his garden to his wife, whose taste and ambition does not often carry her ideas farther than a cucumber-frame; though a small green-house, and even a vinery, as it requires so very little attention (see 3041.), might often be added, in order to enhance the enjoyments of this class of society.

7426. Street-gardens, and the smaller suburban gardens (7287. to 7292.), are the next classes in point of number. They differ from the former in being almost always gardens of pleasure, consisting of a grass-plot (complot, Fr. a design or device,) with a border, or a few patches of flowers in front of the house, and a gravel-plot or grass-plot behind, sometimes substituted by a plot for culinary vegetables and small fruits. Their extent may be from an eighth to half an acre, and they are managed by jobbing-gardeners by the day or year. As the plants and turf are soon injured by the smoky and confined atmosphere incident to these situations, the finer plants and trees do not thrive in them, and the sorts which do succeed, and even the turf, require frequent renewal. Evergreens and early spring flowers, both of the tree and herbaceous kinds, are most to be desired as permanent plants for these gardens; and in summer a display of annuals is made from transplanted plants furnished by the jobber, whose great object ought to be to keep up a succession of flowers, and to keep the grass and gravel in order, and the whole perfectly neat.
STATISTICS OF GARDENING.

7427. Tradesmen's villas (7284.), of the smaller kind, may contain from a fourth part to a whole acre, and are commonly managed by a sort of hybrid gardener, who acts also in the capacity of groom, or of house-servant. On a larger scale they are managed by master gardeners of the lowest kind, as from such situations they can seldom rise to be head gardeners. Besides attending to the duties of the jobber, as to suburban gardens, the citizen's gardener ought to study to procure early and late crops of the vegetables most in use; as peas, kidneybeans, potatoes, turnips, &c., because at these seasons they are dear to purchase. Main summer crops are of less consequence, as they may be procured cheap at market. For similar reasons, he ought never to be deficient of salads, pot and sweet herbs, tart plants, &c., as these are dearer to purchase in proportion to other vegetables, because less in demand. If there are frames, hot-beds, and hot-houses, the same general principles are to be observed, viz. when the whole of what is necessary for the consumption of the family cannot be raised, to raise such crops as, whether from their kind, or the seasons at which they are grown, are most dear to purchase.

7428. Where amateurs of gardening have gardens, they are generally cabinets of rural beauty, however small. We may offer as examples that of R. A. Salisbury, Esq. which consists entirely of plants in pots, which fill a court of a few yards square in Queen-street, Edgeware Road, London; and that of Topham, of Elkins's-row, Bayswater, which is not much larger than that of Salisbury, but in which the choicest flowers are sunk in pots, and changed whenever they begin to fade. This garden is a speck of perfect beauty in its kind. There are a few plots round London similarly treated, and but a few. On a larger scale are numerous amateur gardens; that of the Comte de Vande, at Bayswater, contains two acres, and is remarkable for its botanical collection, its standard roses, and the neatness with which it is kept: but the plan of the garden, its cul de sac walks, ill proportioned borders, and paltry boundary fence of pales, spoils every thing.

7429. The gardens of connoisseurs vary in extent; perhaps the largest and best furnished is that of Knight, the first of all horticultural connoisseurs, at Downton Castle, which, with the experimental ground, contains several acres, and various hot-houses, pits, and frames. In general these gardens are to be considered as horticultural workshops, and beauty and order is not to be looked for. Regular gardeners are very seldom employed. Knight says (Hort. Trans. iv. 17.), "My gardener is an extremely simple laborer, he does not know a letter or a figure." One horticulturist with whom we are acquainted, employs only women; another, only boys; and several do all the work themselves.

7430. Suburban or citizens' villas (7285.) may be considered as occupied by a more wealthy class of citizens; or if not more wealthy, possessing more of the taste and ton of good society. These gardens or residences contain always a portion of lawn or field, as well as a kitchen-garden and shrubbery, and may extend from one to ten acres. They generally contain hot-houses of some kind, and are managed by a regularly bred master-gardener. Besides attending to the duties of a tradesman's gardener, he must bear in mind two things; first, as the families who occupy such places are generally constant residents, he must provide enjoyment both of the agreeable kind from the flower-garden and plant hot-houses, and of the useful kind from the culinary and fruit-garden, for every month in the year; and secondly, he must attend to the habits of the family as to the kinds of productions and enjoyments preferred. The great art of deriving enjoyment from a country-residence of this description, is to provide an interest, a hope, and a fear, for every season, or even for every month in the year. By observing the chapter of monthly productions of horticulture (6038.), and the table of monthly floricultural productions (6741.), the resources which these branches afford are readily discovered. There are also other resources in the nature of culture; such, for example, as raising flowers or fruits from seed. In this view it is good to have some seedlings of early and late flowers, as of the polyanthus and dahlia; of early and late fruits, as of the currant or strawberry, and apple, to come into flower and bearing every season. Other devices for exciting and keeping alive interest will readily occur to the reflecting gardener.

7431. With respect to the habits of a family, it is not only the duty of a gardener to grow those vegetables, fruits, and flowers, of which the members consume the most, or of which they are fondest; but he must also look for other habits of enjoyment; as whether they are fond of walking in the garden, and at what times and places, so as to have every thing in the condition and order best adapted for those purposes. Some delight in smells, and for such, the most odorous plants should be distributed along the walks; others in sounds, and for these, the trees and plants which produce the fruits preferred by singing birds should be planted; or birds, in portable avaries, distributed through the grounds. Some, in walking, may prefer not being seen by workmen, or at least not meeting them in the paths on which they enjoy this mode of recreation; others may take delight in seeing work going forward, and even in asking questions of the operators.
7432. In all families there are invalids at some time or other, and a great object is to render the garden an alleviation to their sufferings. Some afflicted in the lower extremities can only walk on grass-walks; others, from asthma, may not be able to stoop to smell to or gather a rose or a gooseberry; others may require to be carried round the hot-houses in a chair, or wheeled along the walks reclining on a couch, and covered with a glass case. Grass-walks, standard roses, and gooseberries, elevated pots of plants, hot-house paths uninterrupted by pots, and gravel-walks smoothly rolled, are obvious luxuries for such persons. A sick horticulturist, confined to his chamber, may derive some enjoyment from having pots of plants brought before him for a few minutes, to show him their progress; and also by relations of what work is going on, and what articles are vegetating in the garden. When life is under the pressure of disease, any object or measure which can divert the attention for a moment affords relief; for though night cannot be turned into day without the presence of the sun, its darkness may be lessened by a speck of the dimmest day-cloud. It does not often happen that residences are laid out purposely for invalids; but where this is the case, the designer ought to contrive gently inclined planes instead of steps or stairs, and to avoid all corners in walks and paths. Easy turnings in walks are also a great luxury to studious persons, who think as they walk. For this reason, an author, if he can afford any other garden than a pot of mint, should surround his plot with an oval path, that he may walk on without end, and without any sensible change in the position of his body.

7433. Whether a family is of retired or public habits ought to be noticed by the gardener. A retired family will derive most satisfaction from the useful products, and the personal recreation they can take in their garden. A public or fashionable family, on the contrary, from its beauty, high order, and keeping. Beautiful objects are formed to be admired, that is their use, and what renders them so desirable, and their possessors so much envied; therefore those who possess beautiful objects in order to derive the enjoyment they are calculated to confer, must court applause by inviting such friends as are likely to become admirers. Let no man shut himself up in the midst of beautiful rural nature and think he will be perfectly happy, lest he should be forced with the satirist to ask —

— "What is nature? ring her changes round, Her three flat notes are water, plants, and ground."

7434. To be condemned to pass an eternity in a pleasure-ground, would be perhaps as dull as to pass it in a conventicle. Man is a social being, and never can reject the habits to which this part of his nature gives rise with impunity. To be happy he must see and be seen: it is the operation of this principle that has rendered the most beautiful seats of the country show-places, or places which all the world are invited to come and admire, as Blenheim, Mount Edgecumbe, Hackfall, &c.; which induces others to publish accounts of their seats, as Dr. Letsom of Grove Hill, the late T. Johnes, Esq. of Hafod, &c.; which leads the citizen to place his box or lodge, and the artisan or laborer his cottage or cabin by the roadside; and which, in short, impels the humblest individual to court applause by making his powers, either of purse or mind, known to those around him. A gardener, therefore, must attend to these general principles of our nature, and apply them in his department as well as he can; for much, it is evident, depends on his studying the effect of the scenes under his charge, and keeping them in the most perfect order and neatness for inspection.

7435. Villas. (7278.) The grounds and gardens of this class of residences may occupy from ten to a hundred acres, or upwards; they are generally managed by a head gardener, with one or more journeymen, and probably an apprentice, and with the occasional assistance of men and women laborers. The kitchen and flower gardens of places of this sort are generally good, and well furnished with hot-houses; the shrubbery also is carefully laid out, and planted with choice shrubs and trees; and as the proprietor is generally an opulent commercial man, he is liberal in his annual expenditure. The gardeners at such places are generally well paid, no limits put to the dung, implements, structures, or assistance they may want, and left more entirely to their own discretion than those in the service of country-gentlemen. Their responsibility is, therefore, so much the greater, and they are quite unpardonable if they do not excel in their art, and, above all things, in keeping the whole scene under their charge in the utmost order and neatness. It frequently happens, however, that soon after a gardener has got into such a situation, and become familiarised with his garden, and the habits of his family, he begins to consider his place as a sinecure (sine, adv. and cura; i.e. without care), and instead of arduously endeavoring that the productions of the current year shall surpass those of the year past; instead of adding more and more to the enjoyments of his employers, he begins to try with how little they may be put off; and the object of his ambition, which ought to be to delight and astonish his family, is ultimately lowered to that of contenting them. This sort of lethargic indifference, brought on by plenty and ease, is not peculiar to gardeners; it is a condition of our nature, which also furnishes checks to its increase after a certain
period; but it is the business of cultivated man to apply these checks at an early stage, and thus to lessen the evils to all parties.

7436. The simplest check to indolent gardeners is the demands of their masters, who seeing at other tables, and in other gardens, productions superior to their own, and knowing that they spare no expense, &c. naturally enquire into the cause of the default. This sort of observation when abroad, and comparison with home, ought never to be neglected by those who wish to keep servants of any description to their duty. The deficiencies and bad points of other gardens and gardeners may be let alone; but their excellencies should always be particularised, and dwelt on to our own; and where a failure happens in the one case, the reasons required for the other's superiority in that particular, and our inferiority. If the master ultimately becomes dissatisfied with the condition and produce of his garden, let him first call in the nurseryman who recommended the gardener, as counsel for both sides; and let him consign him to this nurseryman, with such a character as he may be considered to merit.

7437. On the order and neatness with which a garden is kept, so much of its beauty and effect depends, that often as we have mentioned the subject in the course of this work, we must again advert to it. Many excellent gardeners are deficient in these particulars, from causes which, at first sight, would seem calculated to have a contrary effect; such as staying constantly at home in their own gardens, and daily inspecting every part of them. The consequence of this is, that the changes which take place in the growth, decay, or deterioration of objects is so gradual as not to be observed, and that an object seen twice every day for ten days, seems the same thing the twentieth time which it did the first, when, in fact, and to the person who has only seen it two or three times, it is something different. To illustrate this, let us suppose a collection of green-house plants, newly shifted, surfaced, pruned, trimmed, tied, washed, and replaced on the stage, and that one man attends to the watering of them regularly every day for a month. They are newly shifted plants the first day, and consequently require nothing done to them; so they are the second, third, fourth, and so on, even after a week or ten days they are so considered, and this notion now becomes habitual to the attendant. Every day as he enters the green-house to water, he sees, without even opening his eyes, (that is, the idea recurs,) a stage of newly shifted plants, all fresh, and free from weeds and decayed leaves, and wanting nothing; therefore weeds and decayed leaves he never thinks of looking for, but waters on; whilst a stranger, or one who has not seen them for a few days, is struck with the slovenliness displayed, and though perhaps the same thing may take place in his own garden, or his own department in the same residence; he goes away not willing to benefit the other by corrective advice, but "thanking God he is not like this man."

7438. This cause of slovenliness we think there are few gardeners who will deny to be correctly stated; and we think, the cause being discovered, the remedy very easily presents itself. Let master gardeners not inspect every part of what is under their care every day at the same time, and in the same order, but let them omit some parts on some days, occasionally omit the whole, and often vary the time and order of their visits. Let them also, instead of going round to look if such and such scenes are in order, go impressed with the idea of finding them in bad order, in search of particular sorts of weeds, of decayed, damaged, or straggling parts of plants, insects, &c. It may seem ludicrous to add, let him go round sometimes in the night instead of during day; but we are persuaded that viewing particular scenes by the light of a lantern or the moon, would present them in such a new aspect, as would probably show deformities or deficiencies. It is a common observation of servants, that after their master has been a day or two confined with illness, or on the morning after an evening of dissipation, he is generally very apt to find fault and be cross, and difficult to please. This is actually the case, and is satisfactorily accounted for without reference to humor or temper: the master sees faults which before escaped him, because the machinery of his faculties has been deranged, and he sees differently. But why does he see faults rather than beauties? Because it is his business to seek for them, and this impression being habitual on his mind, the strongest images reflected by the eye are of that nature.

7439. Visiting neighboring gardens is another important part of a head gardener's duty. This should be done with a view not only to order and neatness, but also to good culture, intelligence as to the state of gardening, &c.; he should not limit his visits to those near him, but include all the principal gardens for forty or fifty miles round; and he should, at least, once a-year, visit the capital or the metropolis, to inform himself, by means of the nurserymen, and among the numerous first-rate gardens that are always found round capital cities, the horticultural societies, and agricultural libraries, of what is going on in the gardening world.

7440. The mansion and demesne (7270.) is less common than the villa near large towns, but more so in the country. The proprietors are sometimes commercial men, but more generally country-gentlemen. Their extent varies from a hundred to a thousand acres,
or upwards, and, in addition to the park and gardens, they contain a home or family farm managed by a bailiff. The garden-scenery, as in the case of a villa, is managed by a head gardener, sometimes more circumscribed in his operations, but always respectively provided for, both as to his person and garden. The worst point attending residences of this description is, that the business of gardener and bailiff is, sometimes in England, and often in the other districts of the empire, united; and the consequence almost universally is, that the business of both situations is very imperfectly performed. The master's object in attempting this union is obviously the saving of a bailiff's wages, which, it is allowed, is an apparent saving, though certainly not always so ultimately. The gardener and bailiff cannot be present at one time, both in the garden and on the farm; he must pass alternately from the one to the other, and it may be questioned whether the time lost in his absence from both, while going between them or at market, and from the one while on the other, does not more than counterbalance the wages of a bailiff, independently of any other consideration. But the loss both to the farm and garden, in cases of this sort, though not very obvious at first sight, is very considerable when details are entered on. No man brought up as a gardener can at once become a good bailiff; and admitting that he may become one in time, yet he acquires his experience at his master's expense. It is generally imagined that a gardener makes a good arable farmer; but this he does not become without experience; for though he may know what good culture is, and may bring the fields of corn or green crops under his charge into a state of good cultivation, yet he may do this at much too great an expense to afford any profit. But the management of arable land is but a small part of a bailiff's duty; the grand object is the breeding, rearing, fattening, buying, and selling of live stock; and a knowledge of these parts of farming cannot be acquired under several years' experience. In the mean time, the losses to the master by bad marketing must be most considerable. Suppose the gardener and bailiff goes to purchase a few scores of sheep, and a dozen of oxen for feeding, every grazier knows that on the nature of the feel alone, which no man can communicate to another by description, much of the value of the animal depends. But a gardener knows nothing of this feel, and the tact of discovering it is not to be acquired but after such a course of experience as no prudent master, who knows any thing of the subject, would wish a bailiff to acquire in his service. As much might be said on the correctness of judgment required in selecting animals to breed together, and in the shrewdness required for marketing; the latter, a duty totally inconsistent with the retired habits of a gardener.

7441. That some gardeners may become good bailiffs we readily allow, because a man of moderately good natural faculties and persevering application, will acquire any thing; but from the nature of the duties which a bailiff has to perform, and the time he must occupy on the farm and at market, it is impossible he can attend sufficiently to the garden. We have never yet known an instance where the duties of both the offices were well performed by the same person, but almost universally found both the garden and farm deficient in the products expected from them. That the master is content is no proof to the contrary, for kindness better, he naturally considers what he has as the best.

7442. From the country-gentleman's gardener, who does not unite the duties of bailiff, a good deal is expected; he must know his profession well; he cannot probably from limited extent and means produce all he could wish, or that a garden should afford, but what he undertakes to raise he must raise in perfection, according to the kind and season, and the main crops in sufficient quantity, because he cannot, like the citizen's gardener, have recourse to Covent-garden, nor like the villa-gardener, surrounded by neighbors, friends, men and the, to assist him in cases of emergency. He has one duty, which does not belong to either of these classes of gardeners, that of packing and sending fruits and other garden products to town when the family reside there.

7443. The mansion-residence may be considered as including all those between the villa and the royal palace. The dwellinghouses are called houses, halls, courts, or palaces, according to the custom of the country, where they are situated; or castles, abbeys, or Grecian buildings, according to their style of architecture; and mansions or palaces, according to their extent and magnificence. The mansion-residence consists of the same parts as in the mansion and demesne (7270.); it may contain from five hundred to ten thousand acres, or upwards, and the whole is managed in the first-rate establishments by the following officers: — A secretary, who receives the commands of the master, and conveys them to the house-steward, who manages the expenditure of the house and offices, and gamekeeper; to the land-steward, who manages the tenant lands, receiving rents, and seeing to the fulfilments of covenants in leases, repairs, &c.; to the bailiff, who manages the family farm; and to the gardener, who manages the garden-scenery, including the park, as far as respects the trees and grass, and the internal plantations or forests.

7444. The gardener who occupies a first-rate situation has under him a forester, for the demesne-woods and park-trees; a pleasure-ground foreman for the lawns and shrubbery; a flower-garden foreman, a forcing-department foreman, and a kitchen-garden foreman. A horse and two-wheeled chaise is kept for his use, by a boy, who also acts as his messenger and house-servant. He lives in a respectable house, near the kitchen-garden, with a stable and cowhouse not far distant. His wages are from 150l. to 300l. a-year, independently of a free house, fuel, and other advantages. He should be at the head of
his profession when he enters on it; and keep himself at the head of it, by taking care to be informed of every improvement and invention in his line, as they are discovered and made public. He must not only know all that is in books, but must be in advance in knowledge; not only ready to apply all the best practices, but fertile in expedients on extraordinary occasions, and in cases of novelty, difficulty, or emergency. Necessities and difficulties, as they occur, excite the inventive faculty far beyond reflection or study; therefore we can afford little assistance here, except recommending the gardener who is ambitious to excel in his profession, first to store his mind with all the resources of gardening, and next to lay up in his memory as many ideas as he can on all other subjects, but especially on art and science.

Next to books on gardening and agriculture, and the topographical surveys of every kind, he should have frequent recourse to the best encyclopaedias of general knowledge, and observe the operations, and converse much on professional subjects with mechanics and artificers of every description. Much useful information is to be obtained from carpenters, millwrights, and smiths, and all kinds of information may occasionally be applied to use in so varied and extensive an art as gardening.

7443. Some idea of the extent of the duties of a head gardener who fills a first-rate situation, may be had from the chapter of monthly horticultural productions, the table of floricultural productions, and arbiculature and landscape-gardening, as treated of in this work; and therefore all that we shall attempt here, in addition to what has just been offered on the subject of the duties of gardeners holding inferior situations (7426. to 7442.), is to enumerate a few of the expedients, some of them common and others uncommon, which every description of gardener will have occasion to practise more or less; but which more particularly demand the attention of gardeners of the highest class, who, not being limited in expense, are expected not to be deficient in producing all the comforts and luxuries that a garden can afford. We shall arrange these hints under the four departments of practical gardening.

7446. Expedients and anomalous practices in the horticultural department.

To have early crops of herbaceous vegetables in the open air. Sow in pots early in spring, one seed in a pot of the smallest size, put them on a bed of hot-bed, shift into larger pots as they grow, and when all danger from frost is over, transplant with the balls entirely in the finely pulverized rich soil of a hot-beds. For cabbages, carrots, onions, red cabbages, and the rest, plants of all sorts, and spinach may be very early in the cold frame.

Stale-ground is very scarce, and a great quantity is wanted for hot-houses, when you want the spot of ground, collect hedges, and hedges, salading of all sorts, and spinach may be very early in the cold frame.

Turners' bark is scarce. Add spruce, fir, or hemlock, chopped with the straw-cutter to the length of the chips of bark, also chopper to the thickness and pith of heads of cabbage for早就-planted onions and cauliflower, and also spinach and other vegetables in spring and autumn. Sow early some small pots on heat, shift often, and transplant in the warmest situations while the weather is still mild when frost is over.

To forward early sowing crops. Sow in the usual way under cold frames, and remove them when all danger from frost is over. Then run them to the tents, may be sooner by the heath than usual by this practice.

All sorts of cabbage and some crops not like to be removed in time to let those which are immediately to succeed them, be in soil in the cold frame. Forward the succeeding crop in pots, and as soon as the preceding crops have all been removed.

There is no such need for the culinary productions. Forward the brassica tribe in pots, and only head or flower them in the compartments. Instead of hotbeds, which occupy much horizontal space, have cucumbers and melons on hot-walls covered with glass: train other creepers, as love-apples, New Zealand spinach, guards, &c. on upright trellis-work or pales, the potato-hallum to stakes; stick all peas; train gooseberries, currants and other currants or raspberries on support, upon which the bottom of each hole left by the pots; lift the second row; and set them in rows, or the plants with the balls: they will be thus surrounded by air instead of earth. When the tan cools replace them as before.

Grapes of fine fruits are reseeded, for which you have no stocks, and you do not wish to put them on old trees. Dig up some roots of trees of the same kind, and make stocks to them, propagation, and afterwards planting in Knight's manner. (1857.)

Never forget the spraying and building may be performed at any season of the year, though best in certain seasons; as in herbaceous as well as woody plants, on roots and cutters as well as on stems, flowers, and flowering shoots.

Consider the size of plants as a stream that you may direct and modify as you will; but that a great many plants may be propagated from leaves alone, &c.

7447. Expedients and anomalous practices in floriculture.

The gravel-walks nearly and tilt colored; a large party is expected, and you wish to be fresh and florid on the occasion. Water them with water impregnated with lime and yellow or red ochre, according as the natural color of the gravel may be preferable to brown or black. The pleasure-ground is delightful in springing birds. Distribute quicklime and ashes, and other abies in soing, by sealing them with the nails in unseen situations.

The flowering and shrubbery divided in inflorescences, to provide an immediate remedy. Distribute pots of rabbit-smoke (or Persian iris) early in the season, and also bottles of water, containing a solution of sweet-scented water, for those regarded in popular, balm of gilead, and other plants, place these as not to be destroyed and replace them as they are wanted.

To diffuse odours in the atmosphere on particular occasions and during dry weather. Sprinkle the odoriferous plants with the water. A large party is expected at a particular time; to give freshness and bloom to the whole flower-garden, sprinkle every part with water, excepting the walks; if with rose-water, which may be made at little expense when the garden is in flower, and keepers for spraying the hot-houses; so much the better.

You expect a large party to visit the plant hot-houses, and they have been taught to tamper with tobacco the night before. In one distribute the umbelliferous little plants, such as the white and silver firs; in another, sprigs of birch; in another, birch, birch, or other shrubs; but company is expected to go through them at the same time. Give them the heads of sweet-scented flowers, sweet-scented flowers, and so on: then sprinkle with pure water. Or do not put them at all but water them with rose-water; or use a little musk, orange-water, or other similar perfume.

Some of your houses are very insipid from accidents to plants, flowers, or other causes; but company is expected to go through them at any hour of the season. Give them the heads of sweet-scented flowers, and sweet-smelts at that time. Distribute a few choice things in pots not too much, but by selecting, by attracting the attention of the spectator, will help to divert his eyes to other flowers, and to estimate what is concealed by what is seen.

After a dry summer your lawn is covered with coarse bladders, on account of the shallowness of the soil, it is desired to give a temporary green appearance. Water these places with lime and water, mixed with green color, the lime serving as a base.
wall, and place the staves of your spare hot-beds over them in the manner of states.

To boil the hot-water. Procure one or any number of cast-iron, or other strong vessels, which may hold from six to nine gallons, already cold, and of moderate capacity; and place a tube reaching from what is to be its top within an inch of its internal bottom; 

and screw in a stopcock. The vessel being half filled with water, an air-condenser is to be screwed to the pipe, and the air forcibly condensed, then turn the stopcock to prevent the escape of the water; unscrew the condenser, and screw in a stopcock. After that you have made the frame, and the vessel may be placed in the situation where the jet is desired; for it may be either set in an excavation made to fit or concealed by plants; or the vessel may be a vase, or made in any ornamental form. Placing where it is to operate, and keeping it for any length of time, it will be found, by setting it at work, it is only necessary to turn the stopcock, and leaving open the valve of the boiler, it will throw the water from ten to fifty feet or more in height, surmounting hills, as the water is evaporated, and lasting in joint proportion to the quantity of water contained in the vessel, the crisis of the jet, and the compression given to the air. This principle admits of great variety, extension, and modification, and might be made to produce very useful effects; and though these effects be not temporary, they would not be objectionable on that account, as in hot-houses, or in a small, but airy detached house, a constant play of jets of water is by no means desirable.

To produce strong sounds in hot-houses, in the hot-houses, or near arbours, in which Place Zolian harps in proper situations, as in Germany.

To deprave the atmosphere suddenly and powerfully. Charge one of the jet-vessels with air, having previously introduced some water into it; fasten it on the floor of the same, and produce the discharge at the proper time and place, or charge with rose-water.

To direct a stream of detestable air against insects in hot-houses at a distance from the path. Direct the stream through a long tin tube, to carry the jet-vessel with the smoke or air.

To syringe plants without a syringe or engine. Use a brush or birch-broom dipped in water.

To recover plants in hot-houses injured by frost. Shade two or three days from the sun, and keep the temperature very little above the freezing point.

To show the effect of buildings. Erect poles, and stretch canvass, or oil-boats on them, so as to form the true outline of the proposed edifice.

To show the effect of raising ground. Stud it over with stakes of the height intended to elevate the earth, and stretch here and there strips of green canvass, bunting, bax mats, or even green straw or hay-ropes, over these. Hay-ropes, from well-got hay, are cheapest, and, if of sufficient number, answer perfectly.

To give a pastoral and pastoral air to a scene for the moment. Employ a man with a flute to play at particular times; drive cattle to drink at a stream; pass a flock of sheep that way, or employ a dog.

To describe a forest character to particular parts of the park or woody scenery. Introduce shagged horns, and asses; show the remains of some ancient buildings or fallen trees.

To direct the eye to a particular point, either to observe its beauties, or to prevent it from observing some deformities in the same scene. Place a white object there, as a hayrick, man at work with his cost off, white cow, or horse, &c. if the back- ground of the scene be dark; or a white hayrick, or wood; and a dark object, if light. If the scene be a lake, then place a boat at the point to which you would direct the eye.

A handsome tree has lost some branches on one side, or is disfigured by the removal of another tree. Try and arrange the branches by certain strong wires, as is done in green-house plants with threads. To cover a tree rapidly with creepers. Place leathern bags of earth, or pot plants of the sort of creeper desired, here and there on the trunk and principal branches; tie them flat to the tree, so as they may not appear conspicuous.

4748. Expedients and anomalous practices in landscape-gardening.

To render a dell part of the park more interesting. Build a hay-stack there; or erect a shelter for cattle; or on tem- porary occasions pitch a tent; or place a portable hay-rack with food to attract deer or cattle; or send some men to work on the spot.

To vary an extraordinary occasion a dell, undercursoring part of the horizon. Cause a fire to be lighted of green wood, or such materials as by the ascending smoke will break the line in the proper place.

To vary for a few seasons the front of a mass of wood. Nikolaon or Kristol, or some proper places at the surface of the ground, and when dead they will produce a break. For a few weeks; cut a tree while in leaf, so as its leaves may wither and rot, and the water either run as water, or be stopped by a tube or shape, and water the surface with lime-water; when dry the effect of the obstructions will be visible.

To give a forsknowledge of the effect of a great walk in any particular place. Mark it out, and water with lime and yellow ochre.

To show the effect of trees. Use poles with crosses at top, or behalf of the entire trees, the thinnings of plantation, wood.

4749. Expedients and anomalous practices in arbiculture.

A quantity of valuable trees arrive from a distance, very much injured and dried up, and bo late for planting in the usual way, and are to be planted in water, or in a drain, or in the nursery; or plant in pots, and place these on heat, when ripe kids, of the order they begin to grow. A violent wind has blown down a number of trees. Top their tops, and then plant, and arrange their seeds, preserving their height; they will produce effect much sooner than young trees.

4750. To some of these expedients it may be objected, that they are deceits or temporary tricks; but if they are so, they are in the spirit of the scenery to which they belong, and they are calculated only to produce pleasure, not pain to any one; none of them are false- hoods, or calculated to make a thing of one nature appear to be of another. We have not directed the display of artificial fruits on wall-trees, of the fruiting of orange-plants from the shops, of milliners' flowers in green houses, or living figures placed on pedestals as statues, of fountains in mourning by making them run out ink, of altars and temples, with persons in proper costume sacrificing on them, of mock buildings or animals, scoops or painted perspectives; all which and other deceptions are recommended and practised by the French and Dutch.

4751. Gardens of royal palaces. The government-gardens of this country are those of Windsor, Hampton Court, and Kensington; that of Kew being a private royal garden. None of them are in any respect worthy of their rank: the garden at Windsor is without hot-houses; that at Hampton Court consists chiefly of some pine-pits and a vineery; at Kensington, great part of the kitchen-garden is cultivated by the plough, and the only two things which render it worth notice are its pine-stoves, and the public gardens or pleasure-ground. The garden-structures at Kew are in a state of decay, and the gardens are never in first-rate order, often slovenly, and always confined as to arrangements. It is said these things arise from want of funds; and from the low rate at which the operators are paid in these gardens. This seems to be the case, and it is much to be regretted, as it prevents the royal gardeners from displaying their skill and taste. Judging from the pine-apples grown in the forcing-departments at Kensington and Hampton Court, there is reason to believe this would be highly creditable to themselves, and exemplary to the nation.

4752. The royal gardeners were formerly much consulted by private gentlemen on the subject of their profession: this is still the case, though in a much less degree, and more now as to garden structures or culture, than as to matters of design and taste. With reference to this circumstance, the professional skill of royal gardeners ought to be of the first order, as their opinion will always be law to a certain number of the court; but for the culture and produce of the gardens (situated as these now are), less professional skill is wanting in a royal gardener than in a private head gardener, as deficiencies in products can always be made up from the commercial gardens, or from Covent-garden.
Sect. II. Commercial Gardens.

7453. Of commercial gardens, the lowest species are what are called ploughed or farmers' gardens. One or two are to be found near all large towns, and a number round London. They extend from fifty to a hundred and fifty acres or upwards, and are almost entirely cultivated by the plough and other agricultural implements. Their possessors are small farmers, and the chief difference between this farm-gardening, and common farming is, that the green crops that intervene between the corn crops are more highly cultivated, and instead of being consumed on the farm, are sent to market as culinary vegetables, or food for stall-fed cows. The crops of every kind, but especially the green crops, are cultivated in drills, two close together, with a wide interval, by which means abundance of room is left to plough and horse-hoe the broad interval, and to sow a succeeding crop there before the other is removed. In this way two crops are obtained most years, as a specimen of which we shall mention one of the common rotations, viz. 1. Peas, with dung, two rows near each other, and a wide interval; 2. Turnips in the intervals; 3. Drilled wheat between the turnips; 4. Turnips, with dung, in drills after the wheat. These four crops are put in, and removed within two years, the ground being in good heart.

7454. The seed-garden is the next species, and forms one of the points of union between horticulture and agriculture. These gardens or small farms are not numerous, and confined chiefly to two or three counties near the metropolis. They consist of from five to twenty acres or upwards, in part cultivated by the plough; the occupier is not generally a bred gardener, but sometimes is so, and unites with the business of seed-grower that of market or nursery gardener. The seeds he cultivates are generally limited to a few kinds; thus chervil, radish, and cress seeds are grown chiefly in the neighborhood of Saffron-Walden in Essex; cabbage-seeds at Battersea; onions at Deptford; peas in Kent, turnips in Norfolk; rape in Lincolnshire; mustard in the county of Durham, &c. The great art is to grow the seeds true to their kind, for which purpose one grower must not attempt too many varieties of the same species, but he may grow a number of different species, and of varieties of the same species, provided they do not come into flower at the same time. Such seeds as are raised in large quantities, as turnip, mustard, cress, maw or poppy-seed, peas, &c. are either sold privately by samples, to the London or other seedsmen, or exposed publicly in the seed-market in Mark-lane, London, or in local country markets. But for the greater number of seeds, the practice is for the nurserymen about London to grow a sample of it in their own grounds as pure and perfect as possible, and then to send it to the seed-farmer to be sown and cultivated by him, and the seed ripened, cleaned, and sent to the nurserymen, at a fixed rate, by the cwt. or bushel. Flower-seeds are generally grown by nurserymen themselves; many of the other sorts by market-gardeners, and many kinds are received from the head gardeners of private gentlemen.

7455. Grass-orchards (Verger agrestes, Fr.) form the next point of union between farming and gardening. There are a number of them in the cider counties, and in the Vale of Clyde, and Carse of Gowrie. A suitable soil and site are chosen, the surface, if not in pasture, is sown with grass-seed, and standard fruit-trees, chiefly apples and pears, and sometimes, as in Shropshire, plums and walnuts are planted in rows, and properly fenced. They receive little pruning, and generally receive no other care but that of gathering the fruit, which is either made into cider; stored in cellars; or sent immediately to market. As the trees get old and covered with moss or mistletoe, or infected with canker, shanks, or rottenness, they are sacrificed, headed down, and sometimes regrafted or rooted out and renewed, according to circumstances. (See The Orchardist, by Buckncl, and Hints to Proprietors of Orchards, by W. Salisbury.)

7456. Ploughed orchards differ in nothing from the grass-orchards but in being constantly or occasionally under aration. The trees stand in quincunx, and every year the direction of the furrows is changed: thus, the first year it may be ploughed east and west; the second, south-east and north-west; the third, south and north; and the fourth, south-west and north-east. The stem of each tree is thus left in the centre of a square or rhomboid of turf of four feet on the side. The ground is cropped as in common farming, or farm-gardening.

7457. Market-gardens. (7358.) The number of these is considerable; their situation is near large towns or seaports, and their extent from one to fifty acres or upwards; some near London extend to upwards of a hundred acres. The object of all is to produce culinary vegetables and fruit for public sale, either as called for at the garden or garden-shop; as wanted by the green-grocer; or exposed in the public market. Some of these gardens are general, producing every description of culinary fruit and vegetable, hardy, exotic, and forced, in demand; of which, as examples, may be mentioned the Earl's Court garden, of upwards of sixty acres, and with extensive hot-houses, by Gunter; the Hoxton garden, nearly equally extensive, by Grange; and the Isleworth gardens, by Wilmot and Keens. Other gardens near the metropolis are devoted chiefly to particular
crops; as that of Biggs, at Mortlake, to asparagus; some at Battersea, to cabbage and cauliflower; at the Neats-houses, to celery; at Deptford, to asparagus and onions; Charlton and Plumstead, to peas, &c. In some gardens attention is chiefly paid to forcing early, and growing late crops; in others, as at Lambeth, by Andrews, exotic fruits, as pines and grapes, are chiefly grown. At a greater distance from town, articles of easy carriage, as gooseberries, strawberries, asparagus, tart-rhubarb, sea-kale, &c. are leading articles; and in small gardens in the immediate vicinity of the metropolis, nothing is sent to market; but salads, as water-cress, radishes, lettuce, parsley, herbs, and flowers are the chief articles grown, and they are sold in small quantities on the spot. The market-gardeners near seaports direct their attention chiefly to the produce of cabbage, onions, turnips, and such vegetables as are in demand as ships' stores. In most parts of the country it happens, that from bankruptcies, absence of families, and such like causes, the produce of a number of private gardens is sent to market. This is a good deal the case near London; but so much so round Liverpool and Manchester, that scarcely a market-gardener is to be found near these towns. Indeed, many of the citizens there who possess villas and gardens, cultivate them as much for the sake of the disposal of the produce as for their own enjoyment.

7458. Market-gardeners on a small scale have generally been master or head gardeners, who have acquired a capital from a number of years' servitude; those occupying more extensive concerns are generally the sons or successors of other market-gardeners, and possess considerable capital. An important point in the culture of these gardens is to supply abundance of manure and water in dry weather; these always produce luxuriant and succulent crops of leaves, though obviously injurious in respect to flavor. A proper rotation and change of surface are also important; and in smaller crops it is a material point to have the rudiments of one crop always ready to succeed another. Thus radishes, lettuces, and onions are sown on asparagus-beds; the radishes are soon drawn, and succeeded by the lettuces and onions, which are left only in places where they will not injure the asparagus; the lettuces come into use soon after the asparagus is cut, part of the onions are drawn young, and the rest left to bulb. In the alleys between the beds, cauliflower plants are planted early in the season, and between these, at a later period, cucumbers, which, with their runners, cover the vacant parts both of the alleys and beds. Thus six crops are obtained in succession, and the ground is clear by October for landing up the beds. Early cauliflowers are generally a profitable crop. The seeds are sown in August, prickèd out, and planted under hand-glasses, six each under, in October. The glasses are placed in rows, ten feet apart, and at four feet distance from centre to centre in the row: thus an acre contains 1092 glasses. After the cauliflowers are planted, the ground is sown with lettuces and spinach; if the lettuce stands the winter, it is valuable, and grows fast when the soil is stirred round it in March. About this time, four of the six plants under each glass are removed, and planted in a warm situation, or in the sheltered alleys of the asparagus-beds. About the beginning of May the cauliflowers are too large for the glasses, and are just coming into flower. As they are gathered and their roots removed, they are replaced by cucumber-plants, previously raised in hot-beds, and now containing two or more proper leaves. In July the middle of the intervals between the rows of glasses is planted with endive, and between each glass two cauliflower-plants are planted to come in late. Thus five crops are raised, all valuable ones, if the ground was previously in good heart, and was kept frequently well stirred, and quite free from weeds. The following are common rotation: 1. Radishes, carrots, savoys or cabbages, or coleworts; 2. Early turnips, autumn cabbage; 3. Spring turnips, French beans, savoys, or peas and spinach, and leeks or broccoli.

7459. In sowing broad-cast crops it is found of advantage to sow several sorts of seeds together, because some of them may fail or be destroyed by insects after they come up; if all come up and thrive, then such sorts as are least valuable may be treated as weeds. Thus onions, radishes, lettuce, and carrots, are often sown together; sometimes the carrots are weod out, and the best crop is the onions; at other times the onions are weod out, and the lettuce is the main crop. Radishes are often sown with turnips, as a sacrifice to the fly, while the turnips escape.

7460. In general all transplanted crops, and as many sown ones as possible, are drilled; and for bulky crops, as cabbages, peas, beans, &c. it is an approved practice to sow or plant two rows near to each other, and then leave a wide interval, in which a dwarf early crop, or crops of short duration, as spinach, lettuce, &c. is sown. By the time the main crop is at its full size, the inter-crop is removed; the ground is then dry, and is turned over, as cabbages or turnips, introduced, which is ready in its turn to succeed as the main crop. In this way, no part of a market-garden is ever left naked or cropless, at least during summer, and though these intervening crops are often injured when young by the shade of the main crop, yet, if the ground be in high order, they soon recover when freely exposed to the air, and the ground again has a good heart, it is a large system to adopt a rotation, and stir the whole ground well between each crop, because here, the soil being poorer, a greater volume is required to supply the same nourishment: quantity is substituted for quality.

7461. With respect to the commercial value of crops, they must, on the general average, be nearly on a par; if one crop is at any time dearer than another, it is in consequence of being more precarious or expensive to raise; if one article is very dear at one time, it is immediately overgrown, and becomes proportionally cheap. To grow something of every kind is safe for those who have extensive concerns; select things for those who devote their whole attention to small spots; and things long of coming to perfection, as tart-rhubarb, sea-kale, asparagus, &c. to those who have capital. It is never advisable to propagate a dear article very extensively, as every body is likely to be doing the same thing; it is better even to adopt a contrary practice.
7462. A good deal of the profit of market-gardening depends on studying the state of the market; in gathering crops sparingly when things are low, and in sending liberal supplies at times, where, from weather or other causes, they are, or are likely to be high. This requires both judgment and capital, for the needy grower must sell at any price.

7463. Orchard-gardens. These are distinguished from the parterre or field orchards, in being cultivated with the spade, and cropped like a market-garden; indeed, they are so much allied to market-gardens, as hardly to require any separate discussion. In general, several kinds of fruit-trees are cultivated together, as tree-fruits, shrub-fruits, and herbaceous fruits; but some spots, from the soil, and probably superior culture, are noted for particular kinds of fruit, as Twickenham and Roslin, for strawberries; Maidstone, for filberts and cherries; Pershore for currants, &c. An account of the Isleworth mode of growing strawberries has been given in the Horticultural Transactions by Keens, an eminent grower of fruits and culinary vegetables. The filberts are planted in rows alternately with rows of cherry-trees; and, as temporary crops, a row of gooseberries, currants, or raspberries, are planted in each interval. Currants are grown extensively round Pershore, and the fruit sold to the manufacturers of British wines. They are also grown in Kent and Essex in rows eight feet asunder, and four feet from tree to tree. Early in spring the ground is dug, and sown with spinach; to that succeed potatoes, and to those cabbages, which last are gathered as coleworts before winter: four crops, including the fruit, are obtained in one season.

7464. Herb and physic gardens. These are of limited number and extent, and generally occupied along with market or seed gardens. There are one or two for peppermint and a few other herbs, near Edinburgh, and the rest are in the vicinity of the metropolis, and chiefly at Mitcham in Surrey. Peppermint is a principal crop, which requires a moist soft soil, and to be taken up and replanted every three or four years. Lavender is grown to a considerable extent on lean soil, as is chamomile, wormwood, rosemary, thyme, &c. Licorice and rhubarb require a deep free soil; roses, which are grown in large quantities for their flowers, require a rich soil; white lilies and colchicum, grown for their bulbs, require a new soil. In one or two gardens near the metropolis, many species of herbs are grown to gratify the demand of certain classes of medical men, of self-doctors, and of quacks and irregular practitioners. Formerly there were many gardens of this sort; apothecaries generally grew a great part of their own herbs, and collected the rest in the fields; and hence the reason why so many of them formerly were eminent as botanists; but at present the only remarkable herb-garden is that of Messrs. Dicksons and Anderson at Croydon. These herbalists and seedsmen have constantly on sale, at their long established and respectable shop in Covent-garden, upwards of 500 species, including all the varieties mentioned by Culpepper and other herbalists of the 17th century. There are still one or two herb-shops which collect their simples in a wild state; but land is now so generally cultivated, that even if there were a demand for native herbs, this mode would not be very successful. It may be mentioned as a curious fact, that in Weston's time, (say about 1750,) winter savory, chamomile, pennyroyal, peppermint, &c. were grown in the common fields near London, where cattle were turned out all the winter; the scent of these herbs being so disagreeable to these animals as to cause them to avoid them. (Weston's Tracts, &c. 71.) All herbs should be gathered dry, and in sunshine after dry weather; they should be dried in the shade, and when perfectly dried, pressed close by a press or weights, and enclosed in paper. The packets should then be deposited in a dry place, and when opened for use always carefully shut afterwards. The practice of hanging up herbs in loose bundles, tends to dry them too much and dissipate their flavor.

7465. Market flower-gardens. These are devoted to the culture of flowers for sale when in blossom; either cut as nosegays, or in pots. They are chiefly to be found in the neighborhood of the metropolis, where a sort of division of objects exists among them. Some gardens are noted for their roses; others, as that of D. Carter at Fulham, for growing the narcissus tribe; Colville in the King's Road, for geraniums; Henderson at Paddington, for cheap heaths; the Bedford nursery for mignonette; and Smith, at Dalston, for forced flowers of all sorts. These gardens are not large; generally from one to a dozen of acres, and they are occupied by gardeners who have been brought up to this department of their profession. The standard articles of cultivation are roses, especially the moss-rose for nosegays; the monthly rose is also much grown in pots for spring and autumn sale. The sweetbriar is in demand for its odor; honeysuckles, lilacs, mezereons, rhododendrons, azaleas, spiræas, double and scarlet-blossomed jasmines, laburnums, rose-acacias, are in great repute, especially when forced. All sorts of evergreens, as pines, firs, laurels, cypresses, arbor-vitæs, hollies, yews, and above all, laurustinus and box, are much in demand for decorating balconies, flat roofs, areas, courts, lobbies, &c. Potted fruit-trees in bearing have generally a ready sale, and especially the grape and peach.
The common flowers for nagoyas are snowdrop, anemones, narcissi, hyacinths, ranunculus, tulips, liliums, auriculas, polyanthus, carnations, pinks, sweetpeas, wallflowers, many other border-flowers, and most of the annual and biennial kinds. The flowers produced in duration by being placed under glass before fruit approaches, being in pots, are mignonette, stocks of all the sorts, nasturtiums, veronicas, violets, gentians, monthly roses, larkspur, clematis, dahlias, and chrysanthemums. The forced flowers are chiefly the pink tribe, violets, wallflowers, ten-week stocks, common stocks, hyacinths, crocus, narcissi, tulips, tuberoses, iris, rose-campions, sweetpens, lupins, roses, lilacs, weberia, mignonette, &c. The cacti in most common demand are myrtles, geraniums, hyacinths, heaths, camellias, Chinese roses, heliotropes, fuchsias, &c. The flowering plants generally kept in pots are auriculas, polyanthus, pinks, carnations, violets, foxgloves, veronicas, dahlias, chrysanthemums, phloxes, and saxifrages of sorts, most of the bulbs and many of the annuals and biennials. The flowers blown in water-glasses are the hyacinth and narcissus chiefly, and also the crocus, tulip, anemaria, echilium, iris, &c. 7466. Of mignonette, perhaps more pots are sold in and near the metropolis than of any other potted plant whatever; fifty years ago it was hardly known. Next to mignonette may be named stocks, pinks, sweetpeas and wallflowers, among the hardy plants; hyacinths, among the bulbs; and geraniums and myrtles, among the exotics. Some years ago heaths and camellias were chiefly in repute; these being found difficult to keep in living-rooms, the public taste has changed, and the flower-grower varies his products accordingly. All these, and other sorts of plants in pots, are also lent out by the market-florist, to decorate private or public rooms on extraordinary occasions, but especially for those midnight assemblages called routs. This is the most lucrative part of the grower's business, who generally receives half the value of the plants lent out, as many of them, and generally those of most value, are so injured by the heat as never to recover. 7467. Florists' gardens are devoted to the culture of florists' or select flowers for the sale of the plants and roots. There are not many exclusively devoted to this branch, excepting near Manchester and the metropolis. Those near Manchester, Paisley, and most other provincial towns are generally on a small scale, and cultivated by men who have auxiliary resources of livelihood; but near London are some extensive concerns of this sort, particularly those of Miliken and Curtis of Walworth; Davey of the King's Road; Mackie of Clapton, &c; the first is celebrated for tulips and most bulbs; the second for pinks and carnation; the last for auriculas. This is one of the most delicate and difficult branches of gardening, and is only successfully pursued by such as devote their exclusive attention to it. The great difficulty is to preserve fine varieties, and keep them from degenerating or sporting; many gardeners, excellent propagators and cultivators of hot-house and green-house plants, find it a very difficult task to grow a fine auricula or carnation; and their flowers would cut but a poor figure at the florists' shows, either near London or in the country. Much depends on the soil, which requires to be rich and well mellowed by time. It is also the most precarious branch of commercial gardening as a means of subsistence, since the purchasers are not so much the wealthy mercantile class who possess villas, or the independent country gentlemen, in whose gardens fine florists' flowers are seldom seen, as the tradesman and middling class. The income of these being temporary, that is, depending in a great measure on personal exertion, and the current demand for their produce is, of course, easily affected by political changes, which make little difference to the man whose income arises from a fixed capital. 7468. Nursery-gardens. (7393.) In these are propagated and reared all sorts of trees and shrubs, and all other herbaceous plants in general demand: the culture of florists' flowers is often combined to a certain extent, and the dealing in seeds imported, bulbous roots, and garden-implements and machines, is generally considered a part of the business. Hence the designation of nurseryman, seedsmen, and florist, formerly, and still, to a certain degree, common on their sign-boards. Of this class of commercial gardens, there is one or more in most counties of Britain, and a few in Ireland; but the greater number, and by far the most important, are in the vicinity of the metropolis. Their extent near town is limited; some contain only an acre or two, but others occupy forty or fifty acres; in the country where land is cheap, some are of double or treble that extent. In general they have been commenced by head gardeners, who had acquired a little capital, and continued by their sons or successors. In country nurseries, the commoner hardy fruit-trees, and tree and hedge plants, are the chief products: near Edinburgh and the metropolis some embraces every article of nursery produce, as the Hammersmith nursery, unrivalled in the world; others deal chiefly in fruit-trees, green-house plants, or American plants; and some almost limit themselves to particular species, as the camellia, erica, geranium, &c. The Scotch nurseries, and especially those of the northern districts, as that of Gibbs at Inverness, are famous for the raising of forest tree seedlings, which they send in large quantities to all parts of the three kingdoms. 7469. The subject of nursery-culture embraces almost every part of gardening; since no department requires a more general knowledge, or so much attention and practical adroitness. The essential part of the business is the art of propagation; which, in some cases, as in multiplying heaths, and other Cape and African plants, by cuttings, and in raising even the pines, and fir tribes from seed, requires very delicate and accurate manipulation, and constant subsequent care and attention. Even grafting, budding, and layering, require to be carefully, skilfully, and expeditiously performed, and the future progress of the scion, bud, or shoot, carefully watched. Next to propagating, rearing requires attention, and especially transplanting and pruning; on the former depends the state of the roots, and of course the
fitness of the plant for removal; and on the latter, very often, the future figure of the tree. The Dutch and French nurserymen are in some respects superior trademen to those of Britain: they generally remove all plants for sale, especially the ligneous sorts, every second or third year, and continue doing this work until the fruit is in full bearing, the time varying with the kind. The purchaser finds their heads already formed and bearing fruit, and with such tufts of fibrous roots that they suffer very little from removal. Even thorn, privet, yew, and other hedge plants are trained in this way, and ready made hedges may be purchased by the foot or yard. (Bot. Trans. 201.)

7412. Correctness in the names given to plants and seeds of every description, and particularly to fruit-trees. To facilitate this, as to seeds and roots, their names should be written on the various boxes, sacks, and slips, and kept as separate copies from the trees; they should be designated, as far as possible, by names kept on wooden, or better on cast-iron, tallies. Stock and stock-plants of every description, not very generally known, and, if possible, the whole of those planted along the borders, whether known or not, should have their systematic and English names painted on similar tallies; and smaller herbaceous plants in pots, and the flower-beds and borders kept up with a system of numbering. The plant in a healthy, vigorous state, when so headed down to apparently dead or dormant eyes, will soon rush, and regain in a great degree, the lost time; and, indeed, it may always be considered safe to rub off all shoots, not more than the third year, from the head of the trees, providing it be done early in the spring. Trees are not in full health, whether recently transplanted or not, should, in general, be left with their tops on; the leaves on which will prepare nourishment to strengthen their roots, and they can be headed down the following season. Some persons, after the drawing season, fill up the blanks in the lines of fruit-trees with stocks to be budded or grafted. This may be insufficient, and excellent soils for these there is little demand for fruit-trees; but, in general, the best way is to fill up all blanks that cannot be filled up with the tree kind in the proper season, with culinary vegetables, either for the kitchen or for seed, or with flowers to produce seed.

7413. Punctuality, accuracy, and despatch, in executing all orders.

7414. Rather procuring or omitting an article than sending off a bad one, unless under peculiar circumstances, to be explained to the party.

7415. Careful packing, and such as suits the sort of articles, the season, the distance, or the climate to which they are to be sent, as well as cost, &c.

7416. Keeping an exact account of men's time, and being particular inmustering them every morning before the hours of commencing work, and again at the hours of rest and refreshment. This may be greatly facilitated by causing them all to enter and go out at the same gate, which ought to be that at the end of the road, and bell or rope to be run through it, for which reasons also the number on the bark and the published catalogue could readily be referred to. If performed with a small sharp instrument, this practice could do no harm to the tree.

7417. Having one principal foreman or partner for the whole, and sub-foreman for the exotic, American, herbaceous, general nursery, and seed departments.

7418. Having a proper person employed as a traveller; or yourself or partner taking that department.

7419. Acting on all occasions with the utmost impartiality between gentlemen and their gardeners, leaning rather to the latter, in all doubtful cases, as the weaker party, according to the common consent and practice of all mankind.

7420. Paying all workmen, and at all events your foremen, such wages for their labor as may not tempt them either to idleness or pilfering themselves, or to contaminate these practices in others. (Jig. 161.)

7421. Punctuality, accuracy, and despatch, in executing all orders.

7422. Attributing at all times and seasons; and in every part of the nursery to frugality (avoiding mean-...

7423. Attending at all times and seasons; and in every part of the nursery to frugality (avoiding mean-...
cully occurs in beginning almost every business, and is only to be overcome by experience.

The different periods to which different seeds retain their vegetative powers require to be

known by seedsmen, as well that they may not furnish lifeless seeds to their customers,

as that they may not throw away as useless such as are possessed of the vital principle.

Though few seeds are kept by respectable seedsmen above a year, yet in cases where a

partial failure has taken place in the seed crop, most sorts will grow the second year after

that in which they have ripened. Some, however, will keep from two to five or ten or

more years; and others for an unknown length of time.

7485. The latest periods at which the seeds most generally in demand may be expected to

grow freely are the following:

Cabbage tribe. Four years.
Leguminous culinary vegetables. One year.
Essential roots. Beet, ten years. Turnip, four years. Carrot, one year. Parsnip, one year. Radish, two years. Salady, two years. Skirret, four years. Scorzoners, two years.
Spinachous plants. Spinage, four years. White beet, ten years. Orache, one year. Paradease, two years. Herbs

natural of the alders. Two years.

Aquatic plants. Apparatus, four years. Sea-kale, three years. Artichoke, three years. Cardons, two years. Ranunculens, two years. Alhambra, and the thistles, two years.
Asteraceous plants, in general two years. Lettuce, three years. Endive, four years. Burnet, six years. Mustard, four years. Tarragon, four years. Sorrel, seven years. Celery, two years.
Pet-herts and garnishing plants, in general two years; but

Parsley will grow at six years. Dill and Fenem, five years. Curril, six years. Marigold, three years. Horago, four years.

Sweet herbs, generally two years; but Rue and Rosemary, three years; and Hyssop, six years.

Plants used in terts, &c. generally two years; but the Rhubarb only one year; and Goose, Purslan, &c. ten years.

Herbaceous shrubs. The Cucumber and Weeta, ten or more years. Love-apple, Cucumis tribe, and Egg-plant, two years.

Annual and biennial flower seeds, generally two years; but some grow with difficulty the second year; they are seldom kept by seedsmen longer than one year.

Perennial flower-seeds, the same.

Tree-seeds. Stones, two years; and some, as the Haw, three; but they are in general of very doubtful success the second year. Acorns will scarcely grow the second year; Elm, Poplar, and Willow seeds, not at all.

7486. All seeds ought to be kept dry, and the air as much as possible excluded; but those liable to be attacked by insects, as the pea, bean, turnip, radish, &c. should be occasionally exposed to air and friction, by being passed through a winnowing machine. (fg. 283.)

The more rare seeds should be kept in their pods till the season for using. Seeds received from foreign countries should, in general, be sown as soon as possible after their arrival. In packing seeds for the home demand, no particular process is requisite; but in sending seeds to America or the East Indies, the sorts which soon lose their vitality should be enclosed in clay, tallow, or wax, or put up in bottles rendered air and water tight. (291.)

7487. Bulbous roots, with the exception of the anemone and ranunculus, can only be kept out of ground a few months with propriety, though some are often found in the seed-shops as late as May. When thoroughly dry they may be kept in bags or boxes, and the more delicate sorts wrapt up in papers separately. Ranunculus and anemone roots retain their vegetative powers two, and sometimes three years.

7488. The English seed-growers and seed-collectors furnish the greater part of culinary, flower, and indigenous tree-seeds sold in the shops, but a part also are obtained from other countries; as of onion-seed from Genoa; anise, basil, &c. from the south of France; carrot, onion, and a variety of seeds, when the English crop fails, from Holland. The harder bulbs, as crocus, daffodil, &c. are for the most part grown in England; the other hardy sorts are obtained from Guernsey, as the Guernsey lily; the Cape of Good Hope, as Ixia, gladolites, &c.; from South America, as the tuberose; or China, as the Japan lily, &c. The seeds of tender exotic trees and shrubs are obtained from the seed-collectors at the Cape, New Holland, and other foreign settlements; and of others from North America.

7489. The recommendation of head gardeners forms an important part of a nurseryman's duty and care, and one in which he may render essential services to horticulture. He ought to select such as are well qualified for what they undertake, and consider himself as in some degree responsible for the conduct of the person recommended. In addition to this, the nurseryman, in the yearly tour he generally makes among his country customers to receive payments and take orders, should observe whether the person recommended has acted according to his expectations, and should exhort, reprove, or approve, accordingly. The nurseryman, while on this tour, by seeing a number of gardens and gardeners, must, by comparison, be well able to judge of their merits; and by judiciously dealing out approbation or blame, might do much good. The good gardener, who had become slovenly, from not seeing other gardens, or from the indifference of his employer, might thus be recalled to his duty, and the art not suffered to be disgrace by his practice. This is also the time, for gentlemen to state to nursermen the faults they have to find with their gardeners, so that they, by their advice, may endeavor to correct them. The nurseryman who has recommended a gardener, is the only person who can act as a mediator between this gardener and his employer; and we repeat, that by the judicious interference of well informed and experienced nurserymen, much good might be done; gardens kept in better order, and gardeners improved and retained, instead of being removed from their situations without being properly informed of their errors, and a proper opportunity afforded them of amendment.

Sect. III. Public Gardens.

7490. There are very few public gardens in Britain; and we can only refer to the enclosed areas of the public squares and parks of the metropolis and principal cities, to
the botanic gardens of the universities and other public bodies, and to the gardens of the two horticultural societies.

7491. *The public squares* are generally kept in order by jobbing gardeners at a certain rate by the year. The principal part of their business consists in keeping the grass short, by mowing once a fortnight in summer, and rather seldomer in spring and autumn; in keeping the gravel clean, and keeping up a display of flowers in the bed groups.

7492. *The public parks* and other equestrian promenades are mostly managed by officers appointed by government; being once formed, and the trees grown up, they require little annual expense. The Mary-le-bonne or Regent's Park is in part let as a nursery-ground, and, instead of a rent, the occupier is bound to plant a certain number of trees the first year of his lease, to nurse up these, and leave a certain number of them on each acre at the end of his lease. A considerable part of this park is also, as already mentioned, let to private persons for the purpose of erecting villas, which, though it will control the rambles of the pedestrian, will give and maintain a woody appearance, without any expense to the public.

7493. *The botanic gardens* of the universities are under the general direction of the professor of botany, and managed by a head gardener or curator: those, founded by subscribers, or a society, as the gardens of Liverpool, Hull, Glasgow, and Dublin, are under the direction of a committee, and similarly managed. The duties common to curators are the keeping up and increasing the collection of plants; those who manage university-gardens, have, in addition, to furnish specimens of certain plants in sufficient numbers for the use of the professor and students. In some cases, the curator is required to instruct students; and in others, he is permitted to do this, and to take pupils or apprentices for his own emolument. Most gardens exchange, and some, as that of Liverpool, sell plants and seeds.

7494. *On the cultivation of botanic gardens* we shall offer only a few general hints. Instead of the principle of rotation, is here substituted that of a renewal, partial or wholly, of the soil. On shallow soils it is to be effected by removal of the whole, or a proportion of the old soil, and the introduction; and thorough mixture of a proportionate quantity of good virgin loam, or of virgin pest, bog, or sand, according to the plot or border to be renewed. In rock-works, and beds, American grounds, and in most of what may be called particular hot-houses, there is no other way; but in the plots which contain the general arrangements, deep trenching may partially or wholly supply its place.

7495. *Manure* cannot altogether be dispensed with in botanic gardens, particularly for some or most of the vegetable animals, which will be included in the cultivation of agricultural, and flower-garden departments; but, in general, decayed leaves is the best manure for all other plants and trees, not in a state of monstrosity or otherwise changed by cultivation.

7496. *Sheltering and shading* are parts of culture which demand very considerable attention in botanic gardens, especially in warm climates, to protect plants which require a moist atmosphere, as some alpines and Americans, require to be closely covered with a hand-glass, and this again partially with a wicker case during the whole summer, even if under the shade of a wall or hedge.

7497. *In sowing, and causing to vegetate, seeds which have been brought from a distance, a good deal of skill is often required*. Sowing in very fine earth in pots, covering them with a bell, and placing them in the shade and in moist heat, is the most likely mode to succeed, whatever climate the seeds may have been sent from. To this, some additional steeping of the seed in pure water, and in water impregnated with oxygenated muriatic acid. Others impregnate the earth with water rich or with water containing some charge of the earth of the pot with the gas, and others invert a bell-glass over it, containing an atmosphere partly or wholly composed of the gas. (See Hill, in Hort. Trans. vol. i. 233.) All these modes, and others suggested by vegetable chemistry, may be tried; but where the vital principle is on board, the first mode will generally be found sufficient. Numerous annual and biennial seeds require to be sown every year, independently of seeds of new sorts from foreign countries. For collections of these in beds or in a general arrangement, the mode of sowing in rows across the bed, is obviously the best; and several rows radiating from a polygonal fally in the centre, is the most economical, as admitting of the greatest number of sorts in the least space.

7498. With respect to management, there are various duties belonging to the office of curator of a public botanic garden which are peculiar to the situation; some of which we shall briefly enumerate.

7499. *Gathering and drying specimens* to maintain the herbarium, and to exchange or give away; frequently inspecting the herbarium to guard against damp and moths; collecting and preserving seeds of every description for the purposes of exchange found in the gardens, and sending to foreign parts for the purposes of exchange of plants. Sir Joseph Banks (Hort. Trans. vol. iii. p. 213) by sowing the seeds of succeeding generations of the zizania aquatica from 1794 to 1804, proved that an annual plant capable of enduring the ungenial summers of England, became, in fourteen generations, as strong and as vigorous as our indigenous species, and as perfect in the duties of a botanic curator, this appears to us much the most important of the services he can render the horticulture and agriculture of his country.

7500. *Collecting wild plants,* and seeking for new species in proper situations; in unfrequented haunts for herbaceous plants; in haunts much frequented by birds, for trees; in bays, and sheltered creeks, and shores, for aquatics; in rocky shores, for alpine plants; among the barren plains, mountains in winter, for mosses; in old forests in winter for licheons, and in spring for fungi, and so on.

7501. *Acclimating plants,* by raising them from seeds, a generation after another, till the final progeny will endure the open air throughout the year. Dr. Walker (Essay) states how the passiflora cicerulis was acclimated by Sir Joseph Banks. "...sowing the seeds of succeeding generations of the zizania aquatica from 1794 to 1804, a plant once scared to endure the ungenial summers of England, became, in fourteen generations, as strong and as vigorous as our indigenous species, and as perfect in the duties of a botanic curator, this appears to us much the most important of the services he can render the horticulture and agriculture of his country.

7502. *Distributing seeds, cuttings, and plants of all sorts,* among all who are likely to keep them, and return some due value on them, but to no one unmeritedly. The Binary gardens, in this respect, have been much and deservedly admired. The easiest mode of preserving a plant in the country is, to render it as common as possible; and the easiest mode of effecting this is, to distribute a few specimens among the nurserymen. From an opposite conduct, many of the plants introduced at Kew, and described in the Hortus Kewensis, are not to be found in the Kew garden; and thus, never having been distributed, are lost to the country. The policy of this garden, for a number of years past, is considered as highly reprehensible: being supported by the public, it ought to have been devoted to its service.
7505. A catalogue of every botanic garden should be printed for exchange, distribution, or sale. Very complete gardens, such as those of Kew, Cambridge, and Liverpool, find it answer to publish printed catalogues, with a view to remuneration by sale; but the legitimate object of a botanic-garden catalogue is, to exchange it with that of other botanic gardens, foreign and domestic; in order, that by comparison of riches, exchange may be made for mutual advantage. For this purpose, it seems desirable, that every thriving establishment should print or prepare a catalogue once a-year, or once every two or three years. To facilitate this, it might be printed by the lithographic process, from a list written in a small hand on prepared paper. By printing only the botanic names, each sheet would contain nearly four thousand names, and consequently three sheets, all the plants, native or introduced into Britain. This might be produced stitched together, all expenses included for a trifle; and as the present law respecting letters stands, might be franked in separate sheets. Thus a cheap communication between British botanic gardens might be formed, and through our foreign ambassadors, these catalogues might be distributed all over the world.

7506. A catalogue may be formed of figures, where it is not convenient to form one of printed names. Thus the possessed or desired plants might be indicated by putting down the numbers placed against the names of the plants in some generally circulated botanical catalogue. If, in the excellent catalogue of Sweet, the genera had been numbered as in the synopsis of Persoon, it would have been the best; in the mean time, Persoon's work, as it is in the hands of most botanists, foreign and domestic, may be referred to; and as an example of the brevity of this kind of catalogue or reference, let us suppose one curator wishes to write to another for Varionia crenata, lineata, bullata, and gloiosa; all he has to do is to write for Pers. (Persoon), 571. (the number of the genus), and 1. to 4. (the numbers of the species desired), and similarly as to all the plants described in Persoon's Synopsis. Ten thousand plants would in this way be represented by about 11,500 figures, which might occupy one sheet of letter-paper. But our Encyclopaedia of Plants, and catalogue entitled Hortus Britannicus, are numbered in such a way as to render communication more facile than any mode of using Persoon, or any other species planterum or catalogue whatever.

7507. The gardens of the horticultural societies, being at present in a state of embryo, do not admit of description. The published plan of that of the London Society (Report on the Formation of a Garden, &c. 1823), appears to us most defective in general arrangement. It is in part executed; and if completed according to that plan, there will be, as we think, a want of grandeur and unity of effect as a whole, and of connection and convenience in the parts. One obvious error that must strike every one that has had no part in making it, is, the forming the arboretum in a large rectilinear clump; and another is scattering the hot-houses and other buildings here and there over the garden. There should, in our opinion, have been three grand parts: a centre for all the buildings of every description, with the exception of entrance-lodges and resting-seats, or shelters, &c.; a circumference, displaying the arboretum, fruticetum, and ornamental flowers; and the intermediate space laid out as culinary, dessert, floricultural, experimental, naturalisation, and nursery gardens. The hot-houses requisite for these different departments might easily have been arranged so as to be included in each of them, and yet forming with the other buildings a whole or connected chain round the central area, and these might have been all heated from the same steam apparatus, and the sheds and other parts and buildings lighted, if desired, by gas. The grand entrance should have presented three carriage-roads: one to the centre, to which visitors might drive and inspect the hot-houses of all the departments, and just take a coup d'œil of the open gardens belonging to them; the two others proceeding to the right and left, and forming a circumferential one, along which visitors might drive round the whole arboretum or shrubbery, and enter if they chose by six or eight communications, at different distances, the six or
eight different open gardens. This is but a first rough sketch of what might have been, but such as it is we leave it as our protest against the present plan, from the details of which the reader will judge for himself.

7508. The London Horticultural Society's garden contains 33 acres, of which 17\(\frac{1}{2}\) are devoted to horticulture (A), 13\(\frac{1}{2}\) to floriculture and arboriculture (B), and 1\(\frac{1}{2}\) to lodges, roads, yards, &c. (C).

7509. The garden of the Caledonian Horticultural Society is not yet in a state to be discussed.

**Chap. III.**

Topographical Survey of the British Isles, in respect to Gardening.

7510. The British isles are naturally and politically more favorable to the practice of horticulture in all its branches than any other country; in no country is so great a proportion of the surface covered with gardens, including, under this term, the parks or landscape-gardens, which surround gentlemen's seats. The beauty and magnificence of these parks, and the villas, mansions, castles, and palaces, of which they are the appendages, far surpass what is to be met with in any other part of the world. The palaces and scenery of Italy are more interesting to artists and classical antiquaries, from the particular associations necessarily connected with their pursuits; but the views of an accomplished and well regulated mind will extend to other kinds of excellence, as well as those of picturesque or classic beauty; and a man that knows to what extent civilisation and refinement are carried in different parts of the world, will look into the interior of these casinos and palaces, their gardens and farms, and enquire to what extent they would contribute, in their propriety, salubrity, furniture, produce, and management, to the gratification of the wants of an Englishman in his present state of refinement. In these particulars he will find them so very deficient, as to admit of no sort of comparison with those of Britain.
7511. Of the state of gardening in each of the different counties of the United Kingdom, the following notices are necessarily imperfect to a certain extent; from defective information some things are omitted, and erroneous statements may exist as to others. In the selection of the names of the principal country-residences, some are undoubtedly admitted which may not have that claim, in comparison to others which are excluded; and others, though they once had that claim, may now have it no longer, from neglect, change of ownership, or even destruction as a country-seat. Most of the descriptive hints, added after the names of country-residences, refer to the state they were in some years ago, some as far back as 1805; and the changes in the names of the possessors that may have taken place since that time must no doubt be the cause of various errors, though we have spared no pains to avoid them. The descriptive epithets, added to the names of places in the southern kingdom, are taken generally from the Beauties of England and Wales (London, 26 vols. 8vo. published from 1801 to 1815); those of Scotland from the beauties of that country (5 vols. 8vo. Edin. published from 1802 to 1809); and those of Ireland from The Traveller's Guide (1 vol. 8vo. Dublin, 1819), and from the information of a correspondent there, well acquainted with every part of that country. We have visited all the counties of Britain ourselves in 1804, 5, and 6, and since been professionally engaged in several of them; and we have also made a general tour of Ireland in 1811. When any remarks occur which are not found in the books referred to, they may, for the most part, be considered as the result of our own observation at these periods or since. From the limited space that we can devote to this part of the work, these remarks are necessarily very few; we have omitted stating any thing as to the indigenous plants; and said very little as to the natural woods or artificial plantations of each county. All the seats which are of established celebrity, and are, or were, what are called show-places, are distinguished by a cross (x) : of most of these places accounts have been published in the local guides, sold in country-towns.

7512. The surface of England is estimated at 32,150,000 acres, almost everywhere cultivated, and nowhere incapable of cultivation; in most places varied — gently and beautifully in some districts, and abruptly and on a grander scale in others. The most hilly and mountainous districts are those of the north, and the most level those of the east. The most humid climates are those of the western and northern counties, as Lancashire and Cheshire; and the most dry those of the east and south, as Norfolk and Sussex. The richest soils, and those in which gardening, as an art of culture, and as a trade, has been carried to the greatest perfection, are those round the metropolis; there, within the circuit of ten miles, it is estimated (Lyson's Environs of London, published 1792 to 1796), 500 acres are employed in raising culinary vegetables; 800 acres covered with fruit-trees and shrubs; 300 acres in medicinal herbs; 500 as nursery and florists' gardens; besides not fewer than 1200 acres employed by farming gardeners in growing potatoes for the market; and 1200 occupied with turnips, cabbages, parsneps, and white beets for milk-cows. Gardening, as an art of design and taste, may be considered as nearly equally advanced in almost all the counties. Some of the most highly kept gardens and country-residences are in Middlesex and Surrey; of the most extensive and magnificent in Oxfordshire, Yorkshire, Nottinghamshire, and Devonshire. The best examples of cottagers' and farmers' gardens are in Essex, Kent, Norfolk, and Lancashire; the seed-gardens are chiefly in Essex and Kent; orchards in Herefordshire, Warwickshire, and Devonshire; and market-gardens and nurseries are distributed according to the extent and population of the different counties. These counties are forty in number, and we shall take them in the order of the circuits made by the judges, being that in which their names are most generally associated in our memories, and that also in which they are not unaptly classed in regard to beauty and character.

7513. MIDDLESEX, occupies the north side of a vale watered by the Thames, and containing 179,200 acres, of which one part is clayey and another marshy, but the greater part productive. As containing the metropolis, it may be considered the richest county in the United Kingdom as to culinary and flower gardening. The depot or market, where chiefly these productions are exposed for sale, is Covent-garden, an open square, laid out with fixed temporary wooden shops and stalls. The vegetables and commoner fruits and flowers are brought in by carts and wagons three days in the week, Tuesday, Thursday, and Saturday, so as to arrive in the market between three and five o'clock; they are then sold by regular salesmen to the retailers of the market, or to green grocers, fruit-merchants, and stall-keepers from different parts of the town; and the general terms are of the same as in the country, the market being cleared of the vehicles and horses by ten o'clock or earlier in the summer, no more remaining in the market than what is found by the different tenants to be sufficient for the local consumption. The more valuable fruits and flowers, such as forced strawberries, peaches, grapes, and pines, and forced roses, hyacinths, and nosegays, during winter, are generally sold by private contract to the fruit-shops in the market, or to others distributed in different parts of the town. The principal fruit-shop is that of Grange, in Piccadilly, who is the king's fruiterer; the principal flower-shop that of Smith, in Covent-garden market. Besides the central market of Covent-garden, there are others in different parts of the town, as the Fleet, Newgate, Borough, &c. which receive very considerable supplies of the leading kinds of vegetables direct from the country; but the forced productions, and the more expensive fruits, are generally brought to Covent-garden, when not disposed of to the shops by private contract.
Gardens at 1063 public name retail.

situation when were and one the garden was mentioned, in Mrs. Gape's garden at Westminster; which garden is, the Thames Embankment was completed for 1698. As the medical garden at Westminster, well stored with plants of other Margin, and what botanical name of the first curator, noticed in 1764. Watts, mentioned both by Kay and Evelyn, was a botanist by profession, but unredi the business in four separate departments; the seed house, the miscellaneous, exotic and house and hardy plants.

Besides an extensive correspondence, and a vigilant attention to procure many good plants and introduced, it is not said that many great plants have been introduced to the country directly or by this way. For this purpose, may be mentioned a person collecting a few and other plants, for instance, for the Cape of Good Hope, in partnership with the Empress Josephine, collecting erics, bulbs, and other plants; and a man in South America.

The whole concern, from its first establishment to the present time, the business conducted with irregular spirit and skill; no expense spared to procure new plants from abroad, and purchase and propagate them when received. The green-houses are extensive, and a house two hundred feet long has lately been erected for fruiting the different sorts of grapes, and another for figs. The proprietor has grounds for the common

Garden Nurseries—In 1757 the first nursery was established by Dr. Compton's Nursery. In 1758 to 1759, Mr. Evelyn, one of the principal gardeners, wrote a book in which he described the gardens, and the fruit-trees, and also the fruits in the garden.

Here are a few of the principal gardeners and nurserymen of the time, who have left their mark on the history of gardening in England:

The first nursery was established by Dr. Compton's Nursery. In 1758 to 1759, Mr. Evelyn, one of the principal gardeners, wrote a book in which he described the gardens, and the fruit-trees, and also the fruits in the garden.

The Bulstrode Nursery.—Messrs. Brooks and Co.,

in this county that might be described mentioned. That of

have been established upwards of half a century, and is carried

on much spirit, collectors being sent out to distant coun-

tries, and many new plants imported. Among those are several

thistles, pulmonies, &c.

The Mendip Nursery.—Established by James Gordon,
gardener to Dr. Sherrard, at Eltham, and passed successively
to the Duke of Wellington, the Earl of Coventry, Mr. C. Forsyth,
and Co.; and Thompson and Co., by whom it is at present
kept up in a very respectable style.

The Mervyn-Coombe Nursery.—Thomas Jenkins, is

been established within the present century; it is of considerable

extent; containing extensive hot-houses for forcing flowers,

for greenhouse-plants, and pits for pine-apples. It also contains

a substantial kitchen-garden.

Other Nurseries.—Of those there are, perhaps, a hundred

...
The gardens, but principally the pleasure-grounds, of the great Earl of Chatham, who expended a considerable sum in laying out in gardens the lands belonging to him in the Middlesex and Surrey, are much in the manner recommended by U. Price. The place is now much neglected. The Temple of Flora, which stands in the pleasure-great, is described by Wheatley, in Observations.

The mansion house of the residence of the late Sir M. Disney. A good house, commanding extensive views of London and Somersetshire. Situated about 10 miles out, and very agreeable.

The house and grounds originally by Holland; the gardens, of much more extent than now, were made by him, and some were sold by public auction, and what remains is neglected.

A beautiful Ionic building, by Nash, to which an elegant conservatory is attached. The situation is beautiful: and rises in the same gap, finely clothed with oaks: the walks were laid out by L. Repton. On the whole, this is one of the most romantic and picturesque places in England, and bears a striking resemblance to that of Ilfracombe Castle, near Ilfracombe in Devonshire.

A fine building, near Epsom; the ground is very extensive, and the general air is very agreeable.

A spacious brick structure on a fine swell in the midst of a park of 500 acres, more varied by irregularities, and of a bolder character than any other residence of the kind within the reach of the Londoner.

The house and grounds originally by Holland; the gardens, of much more extent than now, were made by him, and some were sold by public auction, and what remains is neglected.

adapted for villas and other residences. That part of the metropolis which is within the county, contains a garden-market for the common fruits and vegetables, but it is not extensive. There are several respectable seed-shops, and the greatest seed-factors reside here; in the suburbs and suburban villages, are some good market-gardens, the principal herb-gardens in the kingdom, and some seed-gardens; juicy-berries and cranberries used to be gathered on the commons on Box Hill and Leith Hill, and sold in the metropolis. There are a few nurseries; the county abounds in gardens; there are no public gardens in the county; but the promenade of Greenwich Park, in Kent, adjoins the metropolis. In Stevenson's survey of the county, it is stated, that 5500 acres are employed as farmers’ market-gardens. The greatest gardening author this county has produced is Evelyn, of Woolton, and the most celebrated gardens which have existed in this country those of the Carewes, at Beddington.

7525. There are various commercial gardens.

Farmers’ gardens. — Of these there are a considerable number in the low part of the county, adjoining the Thames. Turnips are grown in abundance and in great perfection, for the cowherds.

Market-Gardens. — There are some highly cultivated and of very considerable extent on the banks of the Thames, especially at Staines, Addiscombe, and Mitcham. The two former places are famous for asparagus, and Battersea for cabbages. There are generally about eighty acres under asparagus in the parish of Mortlake; the greatest grower is Biggs, who has had forty acres under this crop at one time. There are some good gardens near Chertsey, and here the Chertsey or great Surrey carrot is better grown than anywhere else, and the London seedsmen are supplied from the growers with its seeds. The hardy fruits are less generally grown for the markets in Surrey than in Middlesex and Kent; but there is one celebrated grower of exotic and forced fruits, Isaac Andrews at Lambeth, famous for his pine-apples, and being annually among the first who send early grapes and cherries to market. His hot-houses, like those of Gunter and Grange in Middlesex, are all heated by steam.

Herb and Physic Gardens. — These are chiefly in the parish of Mitcham, where the soil is poor and gravelly. The oldest establishment of this description is that of Potter and Moore, who formerly grew most of the articles in the vegetable materials medicae than in vogue. They now grow chiefly roots, lavender, chamomile, the mint, opium-poppy (Papaver somniferum), lahm, blessed-thistle, borage, oxtail, lovage, sage, scurvy-grass, angelica, fennel, pot-marigold, &c. Messrs. Dickson and Anderson, of Covent-garden, seedsmen and herbalists, have a garden at Crosby, and a general collection of such herbs as are only in demand in small quantities.

Market Flower-Gardens. — These are several of them near the metropolis, but none eminently deserving description.

7526. Private gardens, as before observed, are very numerous, and generally well managed, compared with those of most other counties. Cottage-gardens are neat, and often ornamental, and the farmers’ and there are generally extensive nurseries, this class of cultivators being here, as round most large towns, in great part retired tradesmen.

Suburban Villas (fig. 741). — are certainly more numerous, and better laid out, than in most other counties; the driveways and great roads for some miles from town, and render them delightful to the passing traveler.

7527. Villas. We have selected a few; but the number that merit attention is more than double those here named.

Albury Place, near Croydon; Archbishop of Canterbury. A good house in the centre of a park, much varied and well planted; the house lately enlarged and improved.

Maidenhead, in the county of Berkshire; the park, a beautiful piece of ground, of 250 acres, finely wooded, with old Spanish elms. There are some small pieces of water in the park, and a little vein and fountain in the garden. This place was noted in Evelyn's time (267) for the subterraneous passage of 100 yards in length.
made neatly through a hill, but a rock at the south end prevented the design from being completed.

**GARDENS.**

An elegant stone mansion, in a park well stocked with timber, and adorned with a fine piece of artificial water, was intended by Sir Charles at Waverton.

**Barnwell Park,** near Walmington: J. Frederick. An elegant stone mansion in a park of 400 acres, valued here because not intersected by a single footpath.

**Burne Park,** near Epsom: J. M. Ewart, Esq. Worthy of notice on account of the kitchen-garden, which is surrounded by a handsome orangery. It is adapted and ornamented, and an admirable beauty, and the present proprietor.

**Capston Park,** near Egham: Parry, Esq. A new house, in a wood park of sixty acres, lying on the south-western slope of the downs, and adapted by the present owner, the house and the kitchen-garden much improved by the present proprietor.

**Cobham Park,** near Thams Ditton: Colonel Taylor. A stuccoed house, and a park of late years greatly enlarged and improved.

**Green Hill,** near Camberwell: the late J. C. Lettsom, M.A. At the time of his death in 1802, it was the largest park near London.

**Kingwood Lodge,** near Egham: F. Leader, Esq. A stone mansion, near a grounds of 300 acres, in which the grounds were adapted by the late Viscount Cobham, and the house was modernized by the present proprietor.

**Morden Park,** near Morden: G. Ridge, Esq. A handsome seat, surrounded by a park of 200 acres, and well stocked with extensive plantations of shrubs and flowers, and embellished with a great variety of trees.

**Notchley Park,** near Mickleham: W. Locke, Esq. A simple but grand mansion, in an elevated situation, well fitted to receive a residence in a park of 200 acres, as it is placed.

**Pols Hill,** near Colden: Lord Glamis. One of the most beautiful and magnificent residences in England, the park is 215 acres, great part taken from a barren heath; but the house was erected in the last century by the great genius of the estate, a foundation for every improvement. By a sudden flood the water was raised so as to supply a large and beautiful valley, and the buildings and woods were judiciously adapted to the grounds. The park is extremely fine, and the whole was improved by the present owner, the house and grounds being admirably adapted by the present owner. It contains many nut-trees, the nuts of which in some years are sold for 600L., and in others exceed 600L. in value.

**Pole Hill,** near Colden: Lord Glamis. One of the most beautiful and magnificent residences in England, the park is 215 acres, great part taken from a barren heath; but the house was erected in the last century by the great genius of the estate, a foundation for every improvement. By a sudden flood the water was raised so as to supply a large and beautiful valley, and the buildings and woods were judiciously adapted to the grounds. The park is extremely fine, and the whole was improved by the present owner, the house and grounds being admirably adapted by the present owner. It contains many nut-trees, the nuts of which in some years are sold for 600L., and in others exceed 600L. in value.

**Stoke Park,** near Beare: W. Locke, Esq. A stuccoed house, and a park of 500 acres, enclosed with a brick wall.

**Buckland Park,** near Crowth, W. Gee, Esq. Celebrated in the sixteenth century for its gardens, and for the first orange-trees grown in England. The attention paid by Sir Francis Godolphin to the garden by his showing to Queen Elizabeth, who used frequently to visit him there, is recalled by the present owner, the house and the garden of 80 acres, and the estate of 500 acres, and the estate was let to the Duke of Norfolk. At present, Richard B. Wood, Esq., a gentleman of liberal and hospitable dispositions, is the possessor of this grand residence, which is in the occupation of William Gee, Esq., his younger brother.

**Sclerow Hall,** near Esher: Prince Leopold of Saxe Coburg. The park was chiefly planted by Kent, for Felpham Earl of Clares and his family, and adapted by the present owner, the house and grounds being admirably adapted by the present owner. It contains 400 acres, and the estate is in the occupation of Leopold, Prince of Saxe Coburg. The house and grounds are admirably adapted by the present owner. It contains 400 acres, and the estate is in the occupation of Leopold, Prince of Saxe Coburg.
priest as a hunting-seat; the park surrounded by a hill of two miles, and spotted with numerous clumps.

X Oxtedley, near Walton; Duke of York. A demesne of 552 acres, including a fine ancient house with a spacious park, fine tennis walks, a serpentine lake, by Wright, which has recently been taken for a part of the Thanes; and a much admired grove.

X Oaklands, near Guildford; Lord King. The grounds have been carefully managed for three or four generations, and the whole adapted to the modern taste.

X Houghton Park, near Hadleigh; Lord Middleton. A good mansion, on the banks of the Way, sheltered on the north and east by rising grounds, covered with plantation, with an elegant conservatory at the west end of the house, and a kitchen-garden of three acres, containing a good range of hot-houses, glass-houses, and other edifices. A marriage by W. Holland, in a park of 1200 acres, agreeably diversified in surface, containing fine distant views, and tastefully laid out by Brown, who formed a sheet of water, which covers a surface of 50 acres. The manor-house of Wimbledon was formerly one of the first in the kingdom. A survey of it was taken in 1649, and a copy of it is inserted in the 16th volume of Camden's works. The house was painted in fresco externally, like the palace of Navach: in the gardens was an orangerie, containing forty-two trees, in boxes, valued at 10L. each, lemons, citrons, pomegranates, figs: in the maze, wild-marmes, knots, alley, were a great variety of trees and shrubs, a bay-tree, and an Irish azalea. There was a more mile round ground "at the end of the kitchen-garden, trenched, manured, and well watered; the house was pulled down, rebuilt, burnt down, and rebuilt again in 1786. Wotton House, near Dorking; and Rev. J. Evelyn Rosawon. A part of the Evelyns by the time of Elizabeth. It is a low spreading building of no pretensions, surrounded by hills, formed of a small piece of ground, near which the house was pulled down, rebuilt, burnt down, and rebuilt again in 1786. Wotton House, near Dorking; and Rev. J. Evelyn Rosawon. A part of the Evelyns by the time of Elizabeth.

7529. Royal residences.

Kensington, near Hammersmith; the private property of the king, was established by William and Mary, altered by Prince George, and has become universally celebrated, chiefly from the number of its botanical arrangements, and by the number of its gardens.

7530. SUSSEX. A surface of 333,040 acres, generally varied, the soil generally rich, very good bordering on the sea, consists of low undulating hills, or what may be called hilly plains, known by the name of Downs (from downs, Sax. a hill). The northern parts, towards Essex and Kent, abound in natural woods, or remains of woods called woods. This county is not remarkable for its gardens; on the contrary, it is singularly pure, and is more noted for its open parks, where the air is agreeable, and the eye is better in the open air than it does anywhere else in the kingdom. It is well marked out on the banks of the Thames, and exhibit some beautiful views. Queen Caroline, who was a great patron of the arts of gardening, was in many places, in Sussex, the exhibition of the noblest plants, and some beautiful buildings and country seats.

The garden-market at Brighton is at present supplied with all its more valuable articles from London. In this part of the county, which, from the climate and the并与性 of the sea-breeze renders this part of the coast peculiarly unfavorable to gardening. The principal nurseries in Sussex is that of Chichester, by Silverlock, distinguished as the inventor of a hollow wall (fig. 238) which promises to be of real utility both in gardening and cottage-building. There are also many nurseries at Lewes, and near Brighton, where they are well managed. At Brighton, is a celebrated florist, who grows chiefly auriculas and geraniums, and has some trees-seeds from the woods of the Duke of Richmond and Lord Sheffield. The cottage-gardens near the coast are neatly managed, and productive; as are some of the farmers' gardens. There are a few villas near the marine towns; but the principal country-seats are mansions and demesnes.

7531. Of villas and mansions, the following are but a few of those deserving notice.

X Bagham, near Tunbridge Wells; Marquis of Granville. The estate placed, but the grounds extensive, and affording a situation for building, for which a magnificent design has been given by H. Repton. (Observations on Landscape Gardening.) Near the present building the interior of an old church and cloisters have been laid out as a flower-garden, which is much admired by this nobleman and his lady, the Duchess of Dorset.

X Broadwater Park, near Lewes; Lord Whitworth. Both house and grounds have been recently improved by this nobleman and his lady, the Duchess of Dorset.

Cannon Hall, near Woodcote; Lord Seely. A small park near a churchyard, and a small brook, which is dry in summer the effect of both, however, much diminished by planting.

X Fridge Castle, near Tunbridge Wells; Earl Abercorn. A demesne, containing 120 acres, with a large sheet of water round towers, but without any imitation of ancient architecture in the doors, windows, or other details. It stands on a bold eminence in a park of about 500 acres.

742
GARDENS OF KENT.

Up Park, - near Eastbourne; Sir H. Feithertown. A magni-
ificent house, and well wooded park; the timber-trees, in 1743,
valued at L 1,500.

5732. The following are first-rate residences: -
- 
- Arundel Castle, - at Arundel; Duke of Norfolk. A magnificent
castellated structure, partly very old, and partly re-ereected or
more sumptuously finished. The main building is of cir-
cular knob, effected partly by nature and partly by art; the ad-
joining wings are built at low level, and the rest of the park
varied and well wooded. The kitchen-gardens are good, and
notable for fruit and garden-figs.
- Goodwood, - near East Lavant; Duke of Richmond. A magni-
ificent house in the Greco-tan style, chiefly by Wyatt; the wa-
test of the large halls is artfully contrived on the principle of
and the dog-kennels exceed in magnificence and convenience,
even the most splendid and beautiful mansions of the present
and former times. The park includes 2000 acres; behind the house is a
fine grove of cedars, mentioned by Collinson; of the true
specimen plants are cultivated by Miller and Fleminger, and
and it contains a beautiful summer-house; on the plan-
ing grounds is a riding-school, and the park, a race-course.
- Easton Priory Houses, - at Egremont; Earl of Egremont.
A magnificent mansion, fronted with freestone, and surrounded
by statues; in the front an artificial lake formed at an expense
of not less than 30,000L, the water collected from numerous
rills and springs, and conducted by a fine system of pipes.
The park is 12 miles round. It was formerly a little better than
the present state, but well stocked with every variety of British
trees, and also those of America, particularly the wild black
and white oaks; the stags are also numerous, with a few deer
and a few native sheep. The gardens and hot-houses are on a scale
designed to accommodate every other part of this truly
noble demesne.

5733. Royal residence.
- The Palace, or Palace, - at Brighton, is in a mixed style
350 acres, belonging to the Duke of Kent, who has
the former greatly prevails. Exterirolly it forms a singular
350 acres, belonging to the Duke of Kent, who has
an extensive view on every side; and the house includes
excepting the dining-room, the others are low or not
dissimilar in style to the principal edifice. The house
and its situation are remarkable for its situation
by a dome partly glazed. The garden-scenery is tasteless,
stocked with the merest flowers, and shows no exertions for
appreciation.

5734. KENT. A surface of 955,500 acres, considerably diversified
some places; low marshy grounds on the Thames and Medway; open downs near Dover; and an inland,
and wooded, the Saxon word signifying wood, or the woody part
of a country. It is one of the oldest cultivated counties in England; and, from some laws peculiar to it,
possessed of a very diversified and beautiful scenery, and
in the world, unless in some parts of Holland. It is also very productive in vegetables and fruits for the market, and in seeds of
different plants; the two finest objects, it can be said, are the
and one public, formerly a royal park. Philip Miller appears to have been born in this county, near the
metropolis, but where is uncertain. The most celebrated gardens in former times were those of Knowle,
and of Dr. Sherrard at Eitham.

5735. Public garden.
- Greenwich Park, - near Greenwich, originally belonging to
Greenwich Palace, but that being formed into a Hos-
pital for the Royal Navy, the ground of William III., is now
contains 188 acres, walled round by James I., and planted with
and Spanish chestnuts in intersecting rows; a long slip of
wooded land is here, in the actual position of the park of
the Metropolis, from this park, is as interesting a thing of the kind
as one can meet with in this country.

5736. Commercial gardens.
- Farmers' and Market Gardens, - along the Thames,
for the supply of the shipping. Immense quantities of green
produce are sent up to London, and in common farmed lands for the London market. At
Nightingale, near Deptford, and in Southwark, there are
many and large gardens, and at Greenwich and Deptford great quantities of
vegetables, especially onions, carrots, and celeriacs. Deptford
is the greatest grower of asparagus, and sometimes
has 70 or 80 acres under this crop.

- Orichards. - These are chiefly about Lewisham, Maidstone,
and along the banks of the Medway; the principal fruits of the county are the cherry and the pluot.
The plums are also grown, from the walnuts to the strawberry. The latter fre-
and in great perfection, as at Deptford, near Canterbury, belonging to Earl Cowper.

- Asparagus. - Grounds near Greenwich: are grown for the
seedsmen; caulif, radish, kidney-beans, and formerly turnip in
the Isle of Thanet; turnip or Sandwich beans at Sandwich,
and celeriacs at Plaistow. Various kinds of asparagus,
freestone, and many canary-seed in the hundred of
Herne. The cultivation of these vegetables is well conducted through the
county, and shipped for the seedsmen at Feversham. About
twenty men are employed at this business; the growth of
onions for seed, the Deptford variety being in
great repute.

- Market Gardens. - there are two at Greenwich,
and there are also some florists gardens there.

-Cottage gardens. - are not infrequent, though the county is al-
ready fully planted, and most of the orchardists raise their
own trees. The principal is that of John Willmot and Co.
of Lewisham. It was founded by Mr. John Russell, about the
middle of the 15th century, who raised himself by his skill
and industry to the rank of a state gentleman. Russell was
and, after keeping his career, and living many years like a
gentleman, he died on the 1st of December, 1760, to the
amount of 20,000L. The nursery is now carried on by his
son-in-law and successor in quality, the present owner,
who has 70 hands are employed, and about 5000L.
year paid for labor.

- New Cross Nursery, - near Deptford, W. Cormack and
Sons, is extensive, and has long enjoyed a reputation for

5757. Cottage and villa gardens.

- Cottage Gardens. - Besides being neat, as already men-
tioned, these gardens are stocked with ornamental
plants, as hedges, young elms, walnuts, &c. than in most
counties; and they abound more in flowers.

- Gardens of Farmers. - These gardens are of course also superior to those in
most counties; fruit is here a necessary of life, everywhere
cultivated, and all that is not consumed is sent to London,
ready market at Maidstone or London, or is purchased by
the fruit hawkers and the agents who travel through the
countryside.

- Suburban Villas. - A few of these line the roads near the
Thames, at Greenwich, and some of them are excellent;
and there are a number round Blackheath, among villas of a
large and superior kind, and those near Eltham and at
near Greenwich, and all are highly kept.

- Territorial Gardens. - The governor, the proprietor,
Four gradations or terraces cut in the shelving chalk and
flint rock. On the barren walls vines and figs are trained; the
latter in October, while in the low part of the town they
seldom ripen at all. The whole is a state of neglect.

- Colsterdale. - Lord Emley. - paved with bricks of an
e elevation, rapidly declining towards the south, with
fine views over the Thames into Essex; the
counties are small, and diversified, and

- Baden Hill, - near Bexley: J. Smith, Esq. A good
house, and the grounds agreeable, with some natural
woods and walks. The garden is well managed and
beautified, the designs are in the hands of Art.

- Chislehurst, - near Chislehurst; Lady Wilson. A
very pretty and healthy spot; the grounds are
include some beautiful scenery, and fine old trees, especially

- Farningham, - near Farningham; Lord Keith. The house
a good specimen of modern Gothic; the grounds,
which contain thirty acres, are remarkable for a curious
subterraneous passage

- Holsted Park, - near Beckenham; Lord Auckland. An
highly cultivated situation, surrounded by fine Beech-trees.

- Effingham, - near Effingham; Lord Danes. The
park displaying some fine thriving trees over undulating

- Houghton, - near Ashford; Earl Thanet. A square edifice
of Portland stone; the grounds afforded by the Lord
much improved and cultivated, at an expense of

- Goodnestone, - near Kentish Town; W. J. Barrow, Esq.
The grounds beautifully varied by nature, tastefully planted,
and containing numerous picturesque shrubs and coniferous

- Holwood House, - near Beckenham; The favorite residence of
the late prime minister; the house small, but the grounds ex-
tensive and beautifully laid out by H. Repton.

- peri; - near Ickham; T. B. Bridges, Esq. A Gothic
mansion in the Venetian style, enriched by a fine
garden; the park displaying some fine thriving trees over undulating

- Quarry Hill, - near Twombridge; J. Burton, Esq. an eminent
gardener. The grounds are varied, and diversified by the
stone of the stone and flints of the country, with an extensive park,
abounding in undulations and woods.

- Woodlands, - near Blackheath; J. A. Angerstein, Esq. An
elegant mansion in the Venetian style. The ground, diversified

- Footscray Place, - near Footscray; Harris, Esq. The
mansion of freestone, copied from a design by Palladio.
sected near Venice; the park well planted, and embellished with a canal, formed from the Croy river, which flows through the grounds.

Hadleigh Park,—near Seven Oaks; Duchess of Dorset. A magnificent Elizabethan palace, the most modern part of which is dated 1665; the acres. The park is between five and six miles in circumference, varied in surface, and clothed with venison parks, beeches, and elms. The pleasure-grounds, for the greater part, remain in their original taste, and contain some fine old elms, cedars, and other trees. Extensive conservatories, mottoes, recollections, and flower-gardens, with other improvements, have been added by the present proprietor, who is much attached to gardening.

Mote,—near Maidstone; Earl Romney. Formerly a cas- tellated mansion, surrounded with a moat; now a splendid structure on a knob, commanding fine views.

7539. ESSEX. A surface of 1,250,000 acres, of which one part is covered by the Thames, is marshy, and chiefly under pasture, and another part southwards is occupied with the remains of Hainault and Epping Forests; and the remainder in the middle of the arable lands, on which, besides corn, the cut-tieand in pasture and gentlemen's seats. There is a good market at Colchester for vegetables, and in the country markets there, and other places, samples of fruit for sale.

7540. Commercial, cottage, and farmers' gardens. 

Farmers' Market-Gardens. These are extensive in most parts of the county. About Horsford, Darking, and Platwote, immense quantities of early potatoes are grown for the London market.

Market-Gardens. The principal of these are near the metropolis, and at Chelsfield and Colchester; the latter town and Evely, and Purfleet, supply the first early peas from the early potatoes. The gardens in Weetwood Market-Gardens in this county, in Kent, or indeed any where, excepting those of Middlesex and Surrey, have much glass. Some of the gardeners receive more of their stock from this county than from any other. In the low districts, the Thames, great quantities of rye-seed are grown; brown and white mustard are grown in most places; small gardens of almost all sorts round Coggeshall, Colchester, and in the Isle of Mersey; carrot-seeds at Westerfield; cider, coranier, and mace, and poppy seeds (Papaver somniferum), have been raised in the same district. These, with the Marquis of Buckingham's wood at Gosfield Hall, near Braintree, most of the flowers which are grown in England are procured, and hornbeam-seeds from Epping For-

Physic-Gardens. These are, none of these bore mention, unless one or two near Saffron Walden, in which the cultivation of the Thyme, great quantities of rye-seed are grown; brown and white mustard are grown in most places; small gardens of almost all sorts round Coggeshall, Colchester, and in the Isle of Mersey; carrot-seeds at Westerfield; cider, coranier, and mace, and poppy seeds (Papaver somniferum), have been raised in the same district. These, with the Marquis of Buckingham's wood at Gosfield Hall, near Braintree, most of the flowers which are grown in England are procured, and hornbeam-seeds from Epping For-

Florists' and Nursery Gardens. There are few of any conse-

quence.

Cooperage-Gardens. Farmers' Private Gardens, and Suburban Villas, (fig. 753.)--abound and in general very neatly kept; formerly gardens of Chelmsford and Colchester water was much attached to the culture of florists' flowers, and they still continue to be so in a considerable degree.

7541. Of Villas there are a considerable number, from which we select only a few. 

Cooperage, near Thorgan Bay; J. Archer, Esq. A spacious residence, containing a very neat building on an eminence, commanding fine prospects over a well wooded park.

Eastbury House, near Darking; Sir Sterry, Esq. A spacious and handsome mansion, with octagon windows; the grounds rather confined.

Gosfield Hall, near Brentwood; T. Wright, Esq. An octagonal house, with chimneys in the centre; the grounds of limited extent.

Middle Hall, near Greensted; C. Orde, Esq. A new house and good garden.

Langhorne Place, near Stansted; J. Houshill, Esq. A desirable and pleasant residence, lately much improved.

Langhorne Cottage, near Langhorne; T. Spottiswoode, Esq. A handsome house, on a pleasant eminence, and the park and grounds well laid.

Liston Hall, near Boxley; — Campbell, Esq. A handsome modern building, with piazzas, encompassed by railings, and containing several enclosures.

Maidstone Park, near Misden; — Sandy, Esq. The house is ancient; the park seven miles in circumference, and rarely equalled for birch woods, picturesque, sequestered, and romantic.

Twinstead Hall, near Twinstead; J. Marriot, Esq. A space-

hand in building, surrounded by pleasant gardens, over which is a bridge to the adjoining meadows.

7542. Mansion and demesne residences. 

Andley End,—near Saffron Walden; Lord Baybroke. A magnificent Elizabethan structure, of which, according to Lord Walpole, John Thope and Edward Johnson were the architects; the model was procured from Italy, and cost 500l., and the expense of erection was 150,000l. The park is finely wooded, and contains gardens and walks made from the designs of H. Repton.

x Claydon House,—near Aylesbury; J. Trache, Esq. A new house, and greatly improved scenery; the park contains some fine timber.

Colne Acre,—near Little Colne; P. Hills, Esq. A handsome mansion of white brick, surrounded with woods and plantations, among which are several large flower-beds, erected for the use of Alexander Corbet, Esq., architect, in 1791.

Cuff Hall, near Colchester; J. H. Harrison, Esq. A handsome house and pleasant grounds, containing several pieces of water.

Cueppe Hall,—near Epping; J. Cowper, Esq. One of the greatest ornaments of the county. The house, of white brick, has been much improved by Wyatt: the park is large, regular, irregular and well wooded, and the distant prospects grand.

Easton Lodge,—near Dunmow; Lord Maynard. An El-

izabethan mansion in an elevated situation, surrounded by a spacious park, containing some beautiful water.

Footkemore Hall,—near Witham, J. Bullock, Esq. A stately old mansion, and in the grounds, one of the largest-roller rinks in the county.

Felix Hall, near Kelvedon; C. C. Weston, Esq. A ne-

modern mansion, and pleasant grounds, containing a few pieces of water.

x Goffield Hall,—near Gosfield; Marquis of Buckingham. A mansion of the domestic architecture prevalent in Henry VII's reign. The grounds are of limited extent.

Hare Hall,—near Rainford; J. A. W. Bulman, Esq. An ele-

lant mansion of Portland stone, with wings joined by colon-

nades, whose columns are well laid out by Wood, a local landscape-gardener.

Highham, near Witham Woodford; J. Harris, Esq. The house is a high ridge, to the west of which is a fine park, bordering on Epping Forest, and containing a fine piece of water and extensive exotic trees.

Hill Hall,—near Thordon Mount; Sir W. Smith. A hand-

some square mansion, containing a very neat building on an eminence, and fine prospects over a well wooded park.

Ingatstone Hall, near Ingatstone; Lord Petre. An irre-

sizable pile of buildings, a portion of which is noted for its fishponds.

Longford Hall, near Langford; N. Westcombe, Esq. A modern mansion, and a fine wooded park.

Mistley Hall, near Manningtree; F. H. Richy, Esq. The house has lately been much improved, and some plantations and pleasure-grounds laid out with taste.

Narestock Hall,—near Narestock; E. Waldegrave, Esq. A large and handsome mansion, containing some excellent pleasure-grounds.

Newport Hall,—near Audley; Smith, Esq. A handsome mansion on an eminence, with the river Granta at the foot of a lawn in front, from which the house is seen from a distance surrounded by the celebrated mechanic, Dr. Neucott. The plantations and pleasure-ground are thriving and becoming established.

Thornton Hall,—near Brentwood; Lord Petre. The man-

sion, from the very fine seat erected on the Corinthians, the park and grounds well stocked with wood, and many of the trees of great rarity and value, having been planted by a former owner, Petre, in the most beautiful manner; one of the greatest encouragers of botany of his time, and in short the Mercers' Company.

Valentines, near Wanstead; C. Cameron, Esq. A venerable mansion, containing a fine house and a large mansion-house, and containing a number of ancient and pleasing grounds.

Waltham Hall,—near Audley; Smith, Esq. A handsome mansion on an eminence, with the river Granta at the foot of a lawn in front, from which the house is seen from a distance surrounded by the celebrated mechanic, Dr. Neucott. The plantations and pleasure-ground are thriving and becoming established.

Wissall Hall,—near Brook Street; C. Towers, Esq. A handsome manor-house, containing some excellent pleasure-grounds, and distinguished by an embellished prospect-over-ground.
5743. HERTFORDSHIRE. A surface of 392,980 acres, the north part forming part of a chalky ridge which extends across the kingdom in this direction, the rest agreeably varied. The soil is generally loamy or clayey, on a chalky sub-soil; there are many private gardens in the county of almost all descriptions; parks, large gardens, and some market-gardens. The gardens at Moor Park and Cashibury were formerly the most noted in the county.

5744. The villas are less numerous than the de- mesne-residences.

Bewick Park, — near Market Street; Sir J. Schrrib. A handsome seat, and a delight in a delightful situation in stately beech-trees. There is a farm of 760 acres, encl. of 26 acres, part of which is now park. The groves are

Bredt Hall, — near Welwyn; Lord Melbourne. A handsome dwelling, from the designs of Paine; the park and grounds beautiful, and much enriched by the river Lee, which here is formed into a handsome sheet of water. The hamlet of Hinxton is in the direction of Lady Melbourne. [Hinxton Hall; — Morgan, Esq. The park is large, and well furnished with wood and water. Broxbourne Bury, — near Broxbourne; J. Bampton, Esq. The grounds are most exquisitely, and with the park nearly much improved.

Near Royston; Lady Wills. A singular, but not unhandsome mansion, in a pleasant park. Colney House, — near London Colney; E. Anderson, Esq. A handsome and regular mansion, with wings; the offices connected by an underground passage, and completely enveloped in evergreens. The park contains some fine oak and elm trees; the pleasure-grounds are extensive; the kitchen-garden well stocked with the best sorts of fruit-trees; and there is a large greenhouse full of choice plants.

The Grove, — near Warford; Earl of Clarendon. An extensive park, in a threes-mile circuit in circumference, through which the river Gade flows in a divided stream, and is formed into two handsome lakes by a false waterfall, the whole being most contagious by his lordship, who pays the greatest attention to every part of his estate.

Huntly, — near Sacombe; G. Mellish, Esq. The grounds laid out with much taste.

Chilton, — near Herne Hempsted; C. Hilton, Esq. A neat and pleasant grounds in a mixed style between the Georgian and the modern, and with several small modern additions.

Parsley Hay, — near Hertford; Earl Cowper. A fine situation in the park, containing about 10 acres, and laid out in various sorts of walks, shrubberies, and flower-beds, which was begun under the direction of Sir Reginald Abercrombie. The park contains a remarkable large oak, which is supposed to be 400 years old, and has been laid out by Mr. Elizabethean.

A residence of 300 acres, with a handsome mansion erected on what was formerly a palace and park of James I., who, in 1616, gave it to his son, Prince Henry, and his son, Prince Charles, the Earl of Salisbury, enlarged and surrounded it with a wall 14 feet in circumference. When Cromwell's survey was taken it was a large mansion, with handsome gardens, avenues and other masses of trees. The gardens were large, and decorated with high trees, pleasure-grounds, and various kinds of flowers. The great garden contained several acres of flowery ground, which formed a pleasant valley, besides a pensive, private, and laundry garden. In the former were two avenues, as described by Mr. Smith, and one of them in imitation of the king's arms. Tring and Waddesdon are in the parish of Miss Smith. The house is large and convenient, and the park consists of between 300 and 400 acres, and is beautifully varied both with undulations of surface and fine trees.

Woburn Woodhall, — near Woburn; Sir S. Smith, Esq. A spacious and agreeable residence, on one of the finest situations in the country, built by Sir Thomas Rumbold, and the kitchen-garden beautifully diversified by hill and dale, and watered by several small streams, and planted with a great variety of trees, which, when seen through the grounds; it contains fine oaks, many of which are of great magnitude. The kitchen-garden is excellent and well supplied.

Warnsdorger, — near Woreley; Sir A. Hume. A good house and pleasant grounds; and on the hilly and alluvial productions. Sir Abraham having introduced various new plants from China and India.

5745. The following may be considered as first-rate residences.

Cashibury, — near Wadford; Earl of Essex. A spacious Elizabethan mansion, with gardens, 100 acres, in a beautiful situation, containing a river crossing, small mere, and several hills in circumference, abounding in rich scenery and noble seminary, once the residence of William Tristram, the poet. The pleasure-grounds are extensive, and contain a beautiful flower-garden in the Chinese style. The kitchen-garden is well cultivated, and also the flower-garden, in which there was a great encourager of gardening, as is the present. A pleasant seat for the chase near M. Lake, a magnificent Elizabethan mansion, in a finely diversified park, containing a river crossing, a lake, three great oaks, ash, elm, and other trees in the county. There were originally two parks, one for red and the other for fallow deer; and in one of them was a garden which was in existence at the time Charles I., a prisoner at Hatfield. In 1711, the king was lodged in an extensive garden, fitted up for agricultural experiments, which are conducted with great science and carried on by the marchants.

Moor Park House, — near Rickmansworth; W. Brinley, Esq. A magnificent Corinthian mansion, by Giacomo Grange, in a park of 100 acres, containing a large, long, and spacious seat, magnificently laid out; celebrated Lord Castlerockett of Bridgnorth, and afterwards a residence of Lord Anson. The park is finely diversified with oak, ash, elm, and lime trees; and is exactly enclosed. The seat was laid out in 1615 and celebrated seat has been praised by Bacon and Sir W. Temple: and one of its possessors B. H. Sturry, Esq., was unfailingly satiated by his pleasure removing a hill from the front at an expense of 5000l.

5746. BUCKINGHAMSHIRE. A surface of 313,400 acres, hilly, and abounding in some places in natural beech-woods, the soil rich, and on chalk. It does not abound in gardens or residences, but contains one long reclebrated —Stow. The securian must be examined and viewed, as the horses, and the above places, are in points of their several rise from the natural and artificial grounds they descend, and the hedges, as in the gardens of the English country, are laid out by the nurseriesmen procure their stocks for standard rises from the same woods, and when they are to be rooted out. small place of no great rate, but here introduced, because it is very commodious as having a great park, and

Chalfont, — near Beaconsfield; J. Velliers, second duke of Buckingham, in the reign of Charles I. It is a town of 5000 acres, abounding in old oak and beeches. The gardens were formerly kept in good order, and also the farm.

Frome Court, — near Chalfont St. Giles, in 1600, Thomas Hibbert, Esq. The grounds were laid out by the former possessor with much taste and judgment; and are finely ornamented with wood, and adorned with a pleasant pleasure-ground. The annual payment of £3 10s. 6d. to Mr. Hibbert, Esq., the present owner of the estate, is a richly stocked with tender exotics, especially heaths, and other Cape plants.

Beaver, — near Chalfont Redd; a seat founded by George Villiers, second duke of Buckingham, in the reign of Clasfe II. It contains an extensive park, the south side of which is hilly, well wooded, and the windings of the Thames are seen along a beautiful race.

Hollin Dene, — near Beaconsfield; Edbury Waller, Esq. A pleasant residence; and a line of very high trees, and of different sorts, are laid out in the ancient style, varying into a sort of wilderness at the extremities of the walks. The ground near the banqueting-house is very well diversified with walks, shrubs, and flower beds of considerable cost, and the place, on the whole, must have demonstrated the ingenuity of the planter, by the beauty of its perfection, and in high keeping; at present it is rather neglected.

Holtin Lodge, — near Woburn; Lord Frederick Boston. The house is modern and elegant; the grounds are distinguished by high trees, with the wild luxuriance of the woods, which, with the bold appearance of the broken ground, and the undulations of the hill and dale, and furnished with some very fine oak and beech trees. The river Thames, which meanders through the estate, is under the care of T. Torrion from Kew, an excellent gardener; and the whole garden consists of a great variety of flowers, shrubs, and botanic, and laid out from the designs of H. Repton, Esq. in 1814. The farm is managed by a Northumbrian bailiff.

Ashley Park, — near Rickmansworth; Marquis of Buckingham. The ancient abbey, lately pulled down, and a magnificent octagon manor, erected from the designs of J. Wyatt in 1818. The park is in a high degree diversified with trees, and contains some very fine oak hill and dale, and furnished with some very fine oak and beech trees. The river Thames, which meanders through the estate, is under the care of T. Torrion from Kew, an excellent gardener; and the whole garden consists of a great variety of flowers, shrubs, and botanic, and laid out from the designs of H. Repton, Esq. in 1814. The farm is managed by a Northumbrian bailiff.
7540. Bedfordshire. A surface of 200,000 places, and a strong clay in others. It contains Duke of Bedford; and the village of Sundy, on the growing pickling cucumbers, which are sent to the London market, and sold by the bushel.

Amphill Park, — Amphill; Earl of Upper Osney. The mansion, a superb edifice, built in the Tudor style: the park contains 3000 acres, extensive and flat, but furnishes some broken prospects; it has a fine water view, and many ancient oaks.

Hoddesdon, — near Luton; Marquis of Hertford. The house is large, and containing ground front by Adam, Chippendale is 140 feet in length, and inferior only to that of Blenheim. The park is extensive, but has few woods. The house was built for Blenheim in 1741.

Hitchin, — near London; Earl of Hardwicke. The hamlet, built of ancient stone, is entered by the gate-house. The mansion, a fine edifice, was built for Blenheim in 1741. The house was built for Blenheim in 1741. The park contains 3000 acres, extensive and flat, but furnishes some broken prospects; it has a fine water view, and many ancient oaks.

Hitchin, — near London; Earl of Hardwicke. The hamlet, built of ancient stone, is entered by the gate-house. The mansion, a fine edifice, was built for Blenheim in 1741. The house was built for Blenheim in 1741. The park contains 3000 acres, extensive and flat, but furnishes some broken prospects; it has a fine water view, and many ancient oaks.

Hitchin, — near London; Earl of Hardwicke. The hamlet, built of ancient stone, is entered by the gate-house. The mansion, a fine edifice, was built for Blenheim in 1741. The house was built for Blenheim in 1741. The park contains 3000 acres, extensive and flat, but furnishes some broken prospects; it has a fine water view, and many ancient oaks.

Hitchin, — near London; Earl of Hardwicke. The hamlet, built of ancient stone, is entered by the gate-house. The mansion, a fine edifice, was built for Blenheim in 1741. The house was built for Blenheim in 1741. The park contains 3000 acres, extensive and flat, but furnishes some broken prospects; it has a fine water view, and many ancient oaks.

Hitchin, — near London; Earl of Hardwicke. The hamlet, built of ancient stone, is entered by the gate-house. The mansion, a fine edifice, was built for Blenheim in 1741. The house was built for Blenheim in 1741. The park contains 3000 acres, extensive and flat, but furnishes some broken prospects; it has a fine water view, and many ancient oaks.

Hitchin, — near London; Earl of Hardwicke. The hamlet, built of ancient stone, is entered by the gate-house. The mansion, a fine edifice, was built for Blenheim in 1741. The house was built for Blenheim in 1741. The park contains 3000 acres, extensive and flat, but furnishes some broken prospects; it has a fine water view, and many ancient oaks.

Hitchin, — near London; Earl of Hardwicke. The hamlet, built of ancient stone, is entered by the gate-house. The mansion, a fine edifice, was built for Blenheim in 1741. The house was built for Blenheim in 1741. The park contains 3000 acres, extensive and flat, but furnishes some broken prospects; it has a fine water view, and many ancient oaks.
Hengam.—near Hengam; Lord Rosse. An elegant modern mansion, and an extensive park and pleasure-grounds, kept in excellent order.

Hoghton Tower.—near Hoghton; Earl of Westmoreland. A house built in the time of Henry VIII., surmounted by a moat, and adorned by a broad moat and a broad park, is frequented by great numbers of wild fowl. The park comprehends 400 acres, and contains the finest woods in this part of the kingdom. The church is close to the park, and near it a picturesque cottage, inhabited by a person, who keeps one of the finest flocks of the Tollemach family, who possessed the estate in the reign of Edward III.

Hensington Hall.—near Hensington; Lord Hensington. One of the finest seats in the county; the house a modern erection; to the front of which are added a series of large flats, and adorned with fine modern gardens. It is situated on an eminence in an extensive park, which abounds in fine plantations, and is diversified by a large piece of water near the house. The whole of this extensive property has been improved by plantations, which, in a few years, will give a new character to this part of the country.

Torkington Park.—near Bury; Earl of Bute. An unfinished mansion, on a grand scale, built from a design sent from Italy; the park eleven miles in circumference, and containing 1800 acres.

5753. NORFOLK. A surface of 1,240,000 acres; every where flat, fenny towards Lincolnshire; sandy flints in most places; and the rest a strong clay. It contains some good soils near Norwich; and extensive, and highly kept. The farm buildings in old woods, though rather deficient in undulations. Redhouse Hall,—near Pakenham; R. Rusbrook, Esq. A noble spacious mansion with wings, forming three sides of a square; the park very extensive and well wooded, both with timber-trees, and under-growths, fir, oaks, &c. for game. Broadgate Hall,—near Oxford; Marquis of Heligoland. A sporting residence of the marquis; the hall a splendid quadrangular building, crowned with compositrons; the park abounding in covert and other cover for game, with cultivated patches sown with corn and buck-wheat for the same purpose. Wodehouse,—near Wodehouse; C. Horner, Esq. A house of the cream-colored brick of Woolwich, with an Ionic portico, and large terraces, one of the best; the statues for tacked and rendered ornamental. The park is nearly laid out, and contains a handsome ornamental obelisk of freestone.

5754. Villas and demeues residences.

Blickling Hall.—near Aylsham; R. S. Harford, Esq. An interesting ancient mansion, surrounded with a most complete in 1600, at the gate, the same at that time, containing an elegant wilderness and lake. The park consists of 1000 acres, abounds in old trees, and the lake extends in a crescent shape, for a mile, and its greatest breadth is 400 yards.

Felbrigg.—near Cromer; W. Addison, Esq. A house partly of the time of Henry VIII., but subsequently enlarged; the park abounding in old woods, and greatly improved by the late possessor whose taste in such matters is evinced in his letter to Repton. Gillington Hall,—near Yarmouth; Lord Bessford. A neat residence; the house (fig. 745) with some fine old trees, a handsome piece of water, and several ruins of an old church.

Gordon Hall,—near Cromer; Lord Suffolk. The park remarkable for its very extensive plantations.

Hunworth,—near Cromer; R. L. Doughty, Esq. An elegant modern house, situated in a small but very pleasant park, well wooded, and laid out with great taste.

Hillington Park,—near Norwich; M. H. Folkes. A residence, very much improved and the gardens, hot-walls, and hot-houses, rendered very complete.

Holkham Hall,—near Holkham; Lord Woodhouse. A convenient house, in an extensive and beautiful park, richly ornamented with wood and water.

Rotham.—near Wells; Marquis Townshend. A comfortable house, built in 1675, among the grounds, extensively suited for improvement, but not much improved.

Walsingham House.—near Walsingham; H. L. Warner, Esq.

5755. OXFORDSHIRE. A surface of 430,000 acres, considerably varied by ridges, approaching, in some places, to the character of hills; the climate cold, and the soil in most parts thin, on a stony sub-soil. It contains the magnificent residence of Blenheim; some others of great extent, and a botanic garden at Oxford. There are no commercial gardens in the county worth mentioning.

5756. Public gardens.

Public Promenades and College Gardens.—The promenades of Magdalen college are unusual and varied, consisting that they are merely walks round meadows on raised mounds, bordered by trees, and hedge-banked, which are very extensive, and as well adapted for display as the others and in Eltham wood, the largest in England. The private gardens to most of the colleges; their form is generally square or oblong, surrounded by a broad walk, which is intersected by other walks; the trees are of various species, and variously placed, in 1688; that of Trinity for its verdant sculptures; and that of University College, for being laid out by Brown, in the modern style, in 1725.

The Botanic Garden of Oxford.—was founded by Henry Earl of Danby, in 1622; it contains five acres, a green-house and store, and a gardens' house. The first curator was Bobart.

5757. From Brunswick, in whose time, and in that of his son, who succeeded him in 1679, it was more worthy of notice than it has been since. Its present curator is William Baster, A. L. S. and F. H. of England.

5758. Villas and demeuse residences.

Redndon,—near Henley; J. Grote, Esq. Forty acres of most improveable land; the house is in the former a summer-house, from which fine views are obtained through vistas formed by shrubs, the bank of which is dark green being placed, or the fore-ground.

Rosedene—near Henley; S. Gardiner, Esq. A flat place, rendered interesting by every thing that art could effect by planting.

Stone College,—near Stokenchurch; R. Davis, Esq. Truly an elegant cottage-dwelling; neat, commodious, simple, and harmonized with the rural scenery around.
of the grounds, rather low, and close to an irregular sheet of water. This place is mentioned by Wheatley as one of the earliest examples of a forme urbe. The present proprietor has been chiefly interested in the rocks and in the artificial water, which was not surfeit, it may vie with any residence in the empire. There is no abundance of great trees, as the ground is too hilly and broken. 

The ruin, the Temple of Solomon, the Chinese Cottage, and the Barn. The ruin was erected from a design by W. Wyatt; and being set out on the water's edge, partly embowered in trees, and diversified with fragments in the walls, and ivy, it constitutes a truly picturesque ornament when seen from various points of view. The Hermitage is a small, circular, thatched building, situated in the south west corner of the garden, and completely embowered with leaves and trees. It was constructed from a drawing of the Princess of Hessom Homberg, and the material was in keeping with the taste of the time. The Hermitage is the only building that is not allowed to be considered. The surrounding scenery is justly contrived to assimilate with the character of the place, the manor, and the park, and to be concealed from the eye, and to be underwood. These improvements were superintended by Major C. Rushgrove Price, and described by the "author of the Landscapc." (Rouges of Eng. and Wales (1861), t. 268.)

Since the reign of George III., in 1818, the grounds have been respectively kept up by the female part of the royal family who reside the residence.

Windsor Castle. — The principal residence of the British sovereign and at Windsor is a ruinous old palace of Iamb, 1581., and is entirely covered with a wall; greatly improved by Edward II., under the superintendence of Wyat, and finally raised the terrace on the north side; Charles II. repaired and embellished it; but Sir John Vanbrugh, under the direction of W. Wyatt. The avenue in the park was planted by Charles II., who also formed a bowling-ground near it, a large and a fine grove of lime-trees and a small forest. The gardens, which were laid out by a person whose taste was very highly cultivated and possessed, were destroyed during the last and preceding reign.

GLoucestershire. A surface of 800,000 acres; elevated, hilly in many parts, and the climate cold; low, fertile, and humid, however, on the banks of the rivers, as in the Vale of Gloucester. On the borders of Monmouthshire are some woods of lime-trees, from which the wood of willow is one of the finest and agricultural purposes. There are a number of nurseriesmen in this county, of which the principal are

- 7559. The following are first-rate residences:—

- 7560. Since the reign of George III., at Windsor, the grounds have been respectively kept up by the female part of the royal family who reside at the residence.

- 7561. Pillars and demesne-residences.

- 7562. Real residences.
GARDENS

7564. The following are villa-residences:

Blaze Castle, near Bristol; J. Harford, Esq. The house is a fine modern edifice, notably to plan and elevation, but much improved in the first Duke's time; but are at present rather neglected.

Barrington Park, near Ilbury; J. Mounsgrove, Esq. The mansion is a sumptuous edifice, in the Italian style. The park is three miles in circumference, and contains some extensive improvements.

Barington Hall, near Great Barrington; Lord Dynevour. The house and grounds, is a good specimen of a farm house; the park is well wooded, and three miles in circumference.

Blackwater Park, near Malvern; T. Windham, Esq. A handsome mansion and plantations around it well wooded.

Crowne Court, near Upton; Earl of Coventry. A large and fine mansion, with a front of 150 feet, and a park of 500 acres.

Country House, near Withington; J. S. Tell. A villa on a singular plan, situated on an eminence distinguished for the beauty of its scenery.

Hagley Park, near Stour; Sir J. S. Suell, Esq. The house is elegant and compact, and the grounds beautifully variegated and well wooded.

Highammon, near Newnham; Lord Gage. A noble mansion, from which place crab-apples are received by the London scedamb.

7565. Manors and demesne residences.

Baddington House, Sudbury; Duke of Beaufort. The manor house is a large edifice, with extensive plantations.

Beverley Park, near Beverley, Esq. A lovely manor, with extensive grounds, and beautifully disposed around it.

7566. WORCESTERSHIRE. A surface of 500,000 acres; hilly in many places, as at Malvern and Bromsgrove, but in general low and very fertile, as in the Vale of Evesham. There are some good residences. The white onion is extensively grown near Evesham; asparagus and cucumbers for the Birming ham market; apples and currants for their fruit, at Pershore;

Blackmore Park, near Malvern; T. Hornby, Esq. An elegant modern building; the park well wooded, but rather too open in its situation.

Cromwell House, near Upton; Earl of Coventry. A large and fine mansion, with a front of 150 feet, and a park of 500 acres.

Country House, near Withington; J. S. Tell. A villa on a singular plan, situated on an eminence distinguished for the beauty of its scenery.

Hagley Park, near Stour; Sir J. S. Suell, Esq. The house is elegant and compact, and the grounds beautifully variegated and well wooded.

Highammon, near Newnham; Lord Gage. A noble mansion, from which place crab-apples are received by the London scedamb.

Blackmore Park, near Malvern; T. Hornby, Esq. An elegant modern building; the park well wooded, but rather too open in its situation.

White Tower, near Stockton; Lord Foley. A new and very fine residence.

Llanerch House, near Llannerch; T. Jones, Esq. A good brick house, with beautiful grounds, with a piece of water, laid out by L'Angou.

Llancara House, near Newport; Sir Robert Salisbury, Esq. A large and fine house, with extensive grounds, surrounded by plantations, chiefly by Sir R. Salisbury, the late proprietor.

Paradised, near Chester; W. N. Ellis, Esq. An elegant house of freestone; the grounds extensive, celebrated by tourists for their romantic walks and views along a precipice; in a bold situation, containing a fine bird's-eye view of the village.

Highammon, near Gloucester; Sir R. W. Guise. A mansion in the Gothic style, with extensive grounds, chiefly beech trees.

Lady's Cliffe The house, one of Vanbrugh's best designs, in a situation rarely equalled for beauty and grandeur. The park abounds in fine walks and pleasing views, with an extensive lawn and grove, by which the house is approached; and there are good kitchen and flower gardens. The views, towards the high hills, and the lake in the distance, are fine in the extreme, and the grandeur and beauty, and render this place one of the finest in the county.

Lydney Park, near Lydney; R. Hove. C. B. Bathurst. An old manor, and near it some fine woods.

Stour's Hill, near Uley; L. Baker, Esq. A handsome modern edifice, 500 feet in length, and 150 feet in height; situated in the pointed style, and surrounded by fine beech woods.

Lydbury, near Northleach; Lord Stowell. The house is on an eminence, in a pleasant park of 100 acres, embellished by large plantations.

Stirlingford House, near Todddington; C. H. Tracy, Esq. A spacious and beautiful house, with extensive pleasure grounds, in the modern style, and a park of 150 acres.

Walsford Park, near Malvern; S. Wicks, Esq. Situated near the Vale of Evesham, bounded by two quadrangles; with two parks, each between three and four miles in circumference.

Wendover, near Wrington; J. R. de Bere, Esq. A venerable and fac-famined mansion of Henry VIII. It is of a more recent period, and almost unknown, except in the name, of which it is disfigured by some improvements.

Woodford House, near Malvern; Lord Beauchamp. A noble building, situated at the end of a lawn of 1000 acres, and well planted.

Llanerch House, near Llannerch; T. Jones, Esq. A good brick house, with beautiful grounds, with a piece of water, laid out by L'Angou.

Llancara House, near Newport; Sir Robert Salisbury, Esq. A large and fine house, with extensive grounds, surrounded by plantations, chiefly by Sir R. Salisbury, the late proprietor.

Paradised, near Chester; W. N. Ellis, Esq. An elegant house of freestone; the grounds extensive, celebrated by tourists for their romantic walks and views along a precipice; in a bold situation, containing a fine bird's-eye view of the village.

Highammon, near Gloucester; Sir R. W. Guise. A mansion in the Gothic style, with extensive grounds, chiefly beech trees.
extensive, and finely diversified with variegated features, soft and almond-shaped, and acquire, covered with noble plantations of oak, beech, and Spanish chestnut.

Eaton, near Lower Eaton; Matthews, Esq. A romantic situation on the Wye.

Berrington, near Leominster; Rt. Hon. T. Harle. A square mansion of white stone, in a park surrounded by woods, and affording fine prospects. The house is of great size, and surrounded by a beautiful park, which contains a great number of fine trees, and a large wood of oak.

Tiverton, near Monmouth; Marquis of Worcester. A house by Inigo Jones, on the banks of the Towy. This seat was famed for its gardens in Charles II's time, and especially for its delicious fruits. In the apartments of the Marquis of Worcester, it is stated that Sir Thomas Somerset, a 

7568. HEREFORDSHIRE. A surface of 600,000 acres; much varied by hills, some of which approach the character of mountains; diversified by natural chards; and the soil is everywhere deep and rich. Hereafter to be celebrated in gardening history as being R. P. and T. A. Knight. Holwood, near Leadhanger: for the Duke of North-End. The mansion Elizabethan, and kept in perfect preservation as a national curiosity; the grounds pleasant; the old garden on the north, and the new one on the south, are well kept. The house is surrounded by a large park, and a spacious terrace; it abounds in walks, formerly clipped in shape, and not far from it is a fine instance of an acre, and yields annually from twelve to sixteen hundred pounds of potatoes.

7569. ESSEX. Situated near Hockley; formerly the Duke of North. The mansion Elizabethan, and kept in perfect preservation as a national curiosity; the grounds pleasant; the old garden on the north, and the new one on the south, are well kept. The house is surrounded by a large park, and a spacious terrace; it abounds in walks, formerly clipped in shape, and not far from it is a fine instance of an acre, and yields annually from twelve to sixteen hundred pounds of potatoes.

Evesham, near Leadhanger: for the Duke of North. The mansion Elizabethan, and kept in perfect preservation as a national curiosity; the grounds pleasant; the old garden on the north, and the new one on the south, are well kept. The house is surrounded by a large park, and a spacious terrace; it abounds in walks, formerly clipped in shape, and not far from it is a fine instance of an acre, and yields annually from twelve to sixteen hundred pounds of potatoes.

Benington, near Learmouth; Marquis of Worcester. A house by Inigo Jones, on the banks of the Towy. This seat was famed for its gardens in Charles II's time, and especially for its delicious fruits. In the apartments of the Marquis of Worcester, it is stated that Sir Thomas Somerset, a 

7570. SHROPSHIRE. A surface of 840,940 acres; mostly flat, with some hills; the soil generally good. It contains a number of good nurseries; and is celebrated for its great beauty of the place much improved by the correct taste of the owner.

Aston Park, near Oswestry; W. Lloyd, Esq. A most elegant and convenient residence, with a large park; a great variety of walks, wood, and ornamental grounds, and a fine collection of trees.

Bagley, near Newcastle; J. Wedgwood, Esq. A superb mansion of brick, raised on a high position, and surrounded by rich parks and gardens, with an excellent kitchen-garden.

Broughton, near Stafford; Marquis of Anglesey. A magnificent residence, improved from a comparatively complete gentleman, delighted much in fine gardens and orchards. The same gardens were famous in Henry VIII's time, when in possession of William Herbert, who, as we are informed by Evans (Lett. of Wales, 1841), sent two men, by the names of Richards and Williams, to France and Flanders, for the express purpose of studying horticulture, and importing excellent vegetables and choice fruit-trees.
A quadrangular brick building, surrounded, situated in a romantic valley, and surrounded with a charming lawn, had with the high hedges and taste so much improved.

**Ingestre Hall.** — near Stafford; Earl Talbot. A respectable edifice, modernised and altered by the present occupier, with a most charming and extensive landscape.

**Little Aston.** — near Tamworth; Lord Strange. A splendid mansion, surrounded by an extensive lawn, finely varied by terraces and embellished with a noble lake. Over the latter is thrown a very handsome stone bridge, and opposite to it stands an elegant stone conservatory.

**Prestwood.** — near Dudley; Sir Thomas Littleton. A fine mansion, the surrounding pleasure grounds exhibiting a most delightful variety of hill and dale, wood and water, effectually chiseled by the hand of nature.

**Sandon.** — near Newcastle; Lord Harrowby. An elegant mansion, finely situated on the declivity of a considerable eminence, commanding noble and luxurious prospects.

**Sandsfield Park.** — near West Bromwich; Earl Darnmouth.

**Warwickshire.** A surface of 639,700 acres; elevated, not much varied, well wooded towards the north, the other parts fertile in corn and meadow. There are many neat cottage-gardens in the county, especially near Coventry. The principal market-gardens for the commoner culinary crops near that place.

**Aston Hall.** — near Oldbury; J. L. Ludford, Esq. An irregular park, surrounded by an elevated and interspersed seat, is a Chinese temple, by Sir W. Chambers; and in another appropriate spot is a hermitage.

**Aubury Hall.** — near Astley; P. P. Newdigate, Esq. An elegant specimen of the third Gothic, directed by an elegant passport and protege; the park fine and extensive, well wooded, and adorned with artificial expanses of wood and water.

**Bliton House.** — near Blisworth; Hon. J. Simpson. A spacious but irregular mansion, entered by iron folding gates, which contained fine stabling, and extensive grounds, and preserved in all the formality of the old taste. One walk is still termed Addisson's, whose seat this was, and where he generally resided before his marriage to the Countess of Warwick.

**Greatstone Hall.** — near Wylde Green, Greathead, Esq. A singular picturesque combination of rock, wood, meadow, and the windsings of the Avon, with a mansion respectable both in size and character.

**Halsway.** — near Abberbury; D. S. Dugdale, Esq. A handsome seat, near the sea, particularly rich in fine and venerable oaks.

**Wallingford Hall.** — near Coventry; Lord Hood. A capacious mansion.

**Leicestershire.** A surface of 522,940 grazing counties in England. It does not abound in rich, have seldom good gardens.

**Fluornace, near Ashby de la Zouch; W. Herrick, Esq.** The park extolled for picturesque beauty, combined with serenity and sublimity of character; it abounds in venerable oaks, elm, willow, and birch.

**Dominion Park, near Donnington; Marquis of Hastings.** A magnificent pile of ecclesiastical Gothic, by W. Wilkins, surrounded by a park containing very old trees. The building is in a bottom, half sunken, and the approach descending to it has a very bad effect. The pleasure-grounds contain a small piece of water, and were laid out by H. Repton.

**Tipton Hall, near Hawsworth; Lady How.** An elegant mansion, which, with the improvements on the grounds, is said to have cost £100,000. It is in some of the park fine temples and carved seats.

**Derbyshire.** A surface of 720,640 acres; hilly, irregular, and in some parts mountainous; the valleys rich and beautiful. There is a good nursery and florists' garden at Derby, by Joseph Mason, and some neat cottage-gardens in the county.

**Brethby Park, near Brethby; Earl of Chesterfield.** A fine old structure was taken down some years ago, which is said to have been purchased by the present occupier after the plan of Versailles, with terraces, statues, and fountains. (See a bird's-eye view of the Terre d'Argent, and Theatre de la Grande Bernache, and The Topograph, vol. ii.)

**Cowden.** — near Derby; Sir R. M. Wilmut. A neat villa, with a good kitchen-garden.

**Pome Brook, near Repton; Sir Francis Bordett, Bart.** The house is an elegant and substantial modern building; and the park and gardens respectable.

**Lockington, near William Drury Lowes, Esq.** The grounds are naturally much varied, and contain a handsome artificial lake, but the plantations having been made when the geometrical taste was in fashion, do not accord well with the variations of the topography.

**Overton Hall, near Derby; Sir Robert Wilmut.** The house is a large handsome edifice; the grounds were laid out by Eames; the pleasure-grounds occupy five acres, and are very agreeably disposed.

**Wingerworth, near Chesterfield; William Hunlecke.** A noble seat, improved from a comparably bade state (fig. 749) by J. D. Nicholls, who entered on water, and planted some trees, and gave breadth to the lawn in front of the house. (fig. 750.)

Elizabethan mansion of stone, commanding agreeable views. The park and garden are extensive.

**754.** The following are first-rate residences: —

**Coome Abbey (Corn or Camile, a low or hollow place), near Coventry; Earl Caven. A noble mansion, in part by Inigo Jones, in a park of 800 acres, well varied by wood and water.**

**Nagley Hall, near Alcester; Marquis of Hertford.** A spacious mansion, improved by Wyatt, on the summit of a fine rock, and extensive park abounding in majestic oaks, and also in young plantations, with a fine lake and every feature worthy of this noble seat. The garden-rooms are of the first-rate, adapted by the present occupiers for their hot-houses; and for the cultivation of the pines-apple, especially of the Providence kind.

**Warwick Castle.** — Warwick; Earl of Warwick. An ancient Gothic structure, on a steep rock rising from the Avon, with a large garden-court, flanked by towers, and with a gate and porticoes, &c. in a truly baronial style, and in excellent preservation. The park is extensive and finely adorned with fine trees; and a fine lake in the Avon, and as well as a noble lake.

**Weston Hall,** near Hambrook; Sir Charles Atherton, Bart. The pleasure-grounds contain a fine course of broad gravel-walks; and some luxuriant banks and walks, and a lake of thirty acres, low, generally flat, and one of the richest gentlemen's seats; and the farmers, though often

Lockington Hall, near Keyworth; Rev. F. Stony. The grounds much improved by the present occupier.

**Prestwood Hall,** near Trestwood; C. J. Packe, Esq. A large modern mansion and fine park.

**Queeny Hall.** — near Friary; Mrs. Latham. A large building on a finely wooded avenue, with a terrace-wall commanding a very fine prospect of hanging hills with scattered woods and neat villages. (See the plan.)

**Stanton Harald,** near Bredon; Earl Ferrars. A large pile of brick and stone, in a park of 150 acres, containing a lake of thirty acres, and a handsome stone bridge.

**Wendy Hall,** near Leicester; Sir G. C. Hudson. The pleasure-grounds laid out with much taste.

**Wingerworth Castle,** near Matlock; R. Arkwright, Esq. The castellated mansion is romantically situated in Matlock Dale; and surrounded by lawns, rocks, and natural woods, and washed on one side by the Dee. The kitchen-gardens and hot-houses are good and well attended to.

**Wingerworth,** near Chesterfield; William Hunlecke. A noble seat, improved from a comparable bade state (fig. 749) by J. D. Nicholls, who entered on water, and planted some trees, and gave breadth to the lawn in front of the house. (fig. 750.)
757. The following are first-rate residences:

- *Chatsworth*, near Bakewell; Duke of Devonshire. The residence is in the Doric style, and is raised upon a quadrangle in the Grecian style; the park lies sloping to the river Derwent, and is noted for the number of trees, which are much diversified with hill and dale, and plantations. The pleasure grounds are dedicated to a rustic taste, and contain the best artificial water-works in England.

- *Haddon Hall*, near Bakewell; Duke of Rutland. One of the most interesting residences in the Peak, and a pleasure park containing a large lake, by Brown.

- *Craughton Bridge*, near Crapton; Sir G. Robinson. A modern house, surrounded by an extensive lawn and pleasure-grounds.

- *Thrapton Park*, near Deene; Earl of Cardigan. A low _clotted_ structure, with a turreted terminating each wing.

- *Hardwick Hall*, near Normanby; Duke of Devonshire. This house is of stone, and built by Elizabeth Countess of Shrewsbury, whose pistol for building is well known: it is one of the most beautiful seats of the kind which is much noted for the justness of its proportions, and said by Kent, to have been thought a fit pattern of measure and constrivance of a room in which to build a house.

- *Keddleston*, near Derby; Lord Scarsdale. The house is a Grecian pile by Adam of Palladian design. In 1773, it is said that five miles in circuit; it contains a fine sheet of water, with cascades and islands, and a venerable grove of oaks.

- *Oslington Hall*, near Lostoxon; J. Dennison, Esq. The house unites elegance and comfort; the pleasure-grounds agreeably laid out, and the park extensive.

- *Newton House*, near Retford; Folliamb, Esq. An elegant modern seat, surrounded by thriving woods and verdant glades, and watered by a rivulet, which expands to a lake.

- *Stanton*, near Newark; W. B. Emmerton, Esq. A mansion in the style of James I.; the gardens neat and agreeable, and the surrounding scenery picturesque.

- *Thorby Park*, near Newark; Lord Manners. A comfortable house, in a low situation, well backed with rising ground, and well situated, and formed park is thirty-three miles round, and contains some fine pieces of water. The garden and grounds are improved by the late Duchess of Kingston.

- *Wollaton Hall*, near Nottingham; Mr. V'apor, Duke of Portland. A handsome lake by J. Repton: the kitchen-garden cultivated in the time of Speed, but for many years neglected. The park, being laid out by Adam, and modelled by Bridgeman, contains numerous young plantations of oak, sheltered by birch, and other trees, backed by a fine wood.

- *Windwula Hall*, near Muskelton; H. Peckington, Esq. An elegant building with plantations, and grounds very extensive.

757. NOTTINGHAMSHIRE. A surface of 495,360 acres; gently varied, fertile, dry, and healthy, containing the remains of the extensive forest of Sherwood. There are good nurseries, and also some market-gardens and orchards at Retford and Nottingham, and tree-seeds are collected at Worksop and other places.

- *Alton Greatton*, near Nottingham; Sir G. Clifton, Bart. The approach to the house, through a avenue a mile in length, covered with turf, and broad enough for a dozen carriages to drive abreast. The gardens on the side of a hill originally in the ancient taste, but lately remodelled.

- *Cock Hall*, near Nottingham; Sir J. G. Clifton, Bart. A house by Carr, in a bottom, but backed by rising hills, well wooded, and surrounded by neat pleasure-grounds.

- *Clumber Park*, near Worksop; Duke of Newcastle. A large park containing 4,000 acres, and eleven miles in circumference, abounds in plantations, picturesque irregularities, a large piece of water, and a highly enriched bridge. Near the house, which is in a high retaining park is thirteen miles round, and contains some fine pieces of water. The gardens are well landscaped, and were formed by the late Duchess of Kingston.

- *Wollaton Park*, near Nottingham; Mr. V'apor, Duke of Portland. A famous estate, of 1,200 acres, near a noble mansion, and gardens and pleasure-grounds, beautiful and extensive.

- *Baynston Hall*, near Harston; W. J. Emmerton, Esq. A mansion in the style of James I.; the gardens neat and agreeable, and the surrounding scenery picturesque.

- *Thorby Park*, near Newark; Lord Manners. A comfortable house, in a low situation, well backed with rising ground, and well situated, and formed park is thirty-three miles round, and contains some fine pieces of water. The garden and grounds are improved by the late Duchess of Kingston.

- *Wollaton Hall*, near Nottingham; Lord Middlesex. A square structure, with towers at the angles, and an elevated prospect of the country, is surrounded by a park in Queen Elizabeth's time. It is approached by a winding avenue of trees. The park contains extensive grounds, and is nearly as long as the park at Weston Park, near Chester.

- *Scrope Hall*, near Retford; Mr. R. Gell, Esq. A noble mansion, and gardens and pleasure-grounds, beautiful and extensive.

- *Wollaton Hall*, near Nottingham; Lord Middlesex. A square structure, with towers at the angles, and an elevated prospect of the country, is surrounded by a park in Queen Elizabeth's time. It is approached by a winding avenue of trees. The park contains extensive grounds, and is nearly as long as the park at Weston Park, near Chester.

- *Scrope Hall*, near Retford; Mr. R. Gell, Esq. A noble mansion, and gardens and pleasure-grounds, beautiful and extensive.

- *Wollaton Hall*, near Nottingham; Lord Middlesex. A square structure, with towers at the angles, and an elevated prospect of the country, is surrounded by a park in Queen Elizabeth's time. It is approached by a winding avenue of trees. The park contains extensive grounds, and is nearly as long as the park at Weston Park, near Chester.

- *Scrope Hall*, near Retford; Mr. R. Gell, Esq. A noble mansion, and gardens and pleasure-grounds, beautiful and extensive.

757. LINCOLNSHIRE. A surface of 1,783,650 acres; great part on the sea-shore, flat and fenny, the wolds, which occupy the north-east, as the word (Saxon) imports, are hilly and void of wood. The London seedmen receive hemp, turnip, rape, and mustard from this county; and sell there large quantities of parsley-seed, which the farmers sow with their clover, as a preventive to the rot in sheep. Some garden-seeds for the supply of the Yorkshire seedmen are grown in the Isle of Portland.

- *Burwell Park*, near Burwell; B. Lester, Esq. A handsome mansion, in a commanding situation, surrounded by a well-kept and improved park, belonging to Mr. M. Smith, grandfather of the present owner, was physician to Charles I., and is mentioned by Parkinson as one of his patrons in botany.

- *Colby Hall*, near Lincoln; General Barrie. A fine old house, with modern additions, and surrounded by neat plantations.

- *Cockayne Castle*, near Edlington; Duke of Ancaster. An irregular pile, chiefly by Vanburgh, on a beautifully undulated lawn, containing about 400 acres; the park is extensive, and beyond which is a rising ground covered with trees. The park is one of the most extensive in the kingdom; there are three ridges in the park, and a straight line and in different directions. There are some rough forest scenery and great extent of rich yarnd, and if the vale be prevented from being flooded as intended, there would have existed here one of the most magnificent pieces of artificial water next to Blenheim.

757. RUTLANDSHIRE. A surface of 123,000 acres; varied, but composed chiefly of fertile valleys.

- *Burley-on-the-Hill*, near Oakham; Earl Wescleb. An irregular structure, with a well undulated front, and a noble erection, in the Doric style. The park contains 1,050 acres, abounding in large oaks, and all kinds of forest-trees; the lawn is extensive, and contains a grove of nut trees, and other ornamental trees. The entrance-front of the house is a court-yard, separated from the park by a superb trellis-fence, supported by caryatids; the front is a terrrace-wall, 500 yards in length, and 12 broad.

757. NORTHAMPTONSHIRE. A surface of 617,600 acres; fenny towards the north-east; but, in general, elevated, varied, and abounding in country-seats. There are some nurseries; and Cornfield, a florist of some note, at Northampton, is considered one of the first growers of the carnation; and in the market-gardens onions are grown to great perfection.

- *Althorpe*, near Brington; Earl Spencer. A large pile, dated 1685, in a park distinguished by large masses of wood, and a noble expanse of water.

- *Cottet Ashby*, near Ashby; Earl Northampton. A large park; the river Dove passing through it, containing a great lake, by Brown.

- *Crapton Bridge*, near Cranford; Sir G. Robinson. A modern house, surrounded by an extensive lawn and pleasure-grounds.

- *Thrapton Park*, near Deene; Earl of Cardigan. A low _clotted_ structure, with a turreted terminating each wing.

- *Rutland Hall*, near Rothwell; Lord Scarsdale. A very tasteful and improved seat, by the late predecessor of theHon. V. C. Coke, knight.
Upton Hall,—near Northamperton; T. S. W. Sanwell, Esq. A large irregular building, on a gravelly soil, displaying fine views of the distant scenery.

738. YORKSHIRE. A central, and, in part, marine, county of, 3,886,880 acres; the surface varies, containing several mountains, extensive moors, and some royal forests; the subsoil mostly generally rocky or stony; Stotherton, the most extensive, and York, the best gardens at all the towns. It abounds in residences, especially in the West Riding, where nearly 400 are mentioned in The Beauties of England and Wales, as worthy of notice. The farmers' gardens are extensive, the lea and park, and the garden, with the near cottage-gardens. At Sherborne, in the West riding, the wine-sour plum, one of the best baking sorts, bears and thrives on limestone soils, and the fruit is sent to Hull, York, London, and other markets. There is a horticultural society held at Leeds, the chief promoter of which is J. Carr, of St Anne's; and the same garden is a very active botanic and floricultural society, or the present garden at Allerton, near this town, noted when in the possession of R. A. Salisbury, is now a public nursery.

The Hol!l Botanic Garden,—was established in 1818, by subscription. It occupies five acres, and is arranged on the same general plan as before; that is, the shrubbery is laid out chiefly by Shepherd, the curator of that garden. The principal walk begins with a water-fall, about thirty feet, or nine feet broad, and form a total length of nearly three quarters of a mile, and is lined with the most beautiful of evergreen, alpine, and green-house plants; a pond thirty yards in length, for the growth of aquatic, and at the south-west corner of the conservatory, is one of the most high, admitting, though few surrounded by trees, an extensive view of the Humber, the Lincolnshire coast, and the most elevated parts of the country. The garden has, during the last year, been improved by the purchase of ground at a distance without trees, the shady walks of this garden form an agreeable resource as a promenade for the families of the subscribers. The curators are J. H. Wollaston, and A. R. Hope, a juicy apple.

739. Mansion and domestic resid. near York.

Ashlark Hall,—near Rothernor: Geo. Folejims, Esq. Charmingly situated on a eminence rising from the Don, and strikingly beautified by a fine view from this position.

Alverton Manor,—near Knorosehrough; Lord Stuart. An ancient mansion, in a park; extensive, elevated, and charmingly picturesque. It contains a fine octagonal tower, the panelling of which is fine, and a garden, with a number of fine trees, and a charming view.

Birsdal,—near Malton; Lord Mitchell. A spacious and commodious mansion and pleasure-gardens, well planted and arranged.

Bradford,—at Bradford; Hudeor, Esq. In an elegant horticultural situation, a choice nursery, who grow a good variety of exotic plants.

Brockholly Hall, Lincolnshire,—near Eaton; Lord Yorke. A fine residence, on a rising ground, containing a fine Gothic chapel and manselum, by A. W. N. Pugin. The gardens contain a greenhouse, and the kitchen-garden by substituting equal parts for strawberry-fruits, which laid the garden like a closely planted orchard.

Bilham House,—near Doncaster; W. H. W. Esq. The ground's contain a Bedrooms (old, Italian, fine, beautiful; and valuable), and a pleasure-gardens, large and extensive, and the most extensive and richest prospect in Yorkshire.

Bosom Wood Hall,—near Hodon; Sir Clifford Costbar, Bart. A park spacious; though flat, abounding in trees, with extensive walks, and fine views.

Cave Castle,—near Sheffield; J. G. Barnard, Esq. A small but extremely pleasant park, with very large gardens and pleasure-gardens.

Carrage,—near Knarsborough; Theo. Duncombe, Esq. An elegant residence, on a rising ground, containing a great variety of English, and foreign, trees in the park, and a fine sheet of water, bounded with wood, winding its way through a ground of pleasing, and picturesque space; the prospects extensive in all directions on a delightful view. It is embellished with gentleman's residences, and other embellishments.

Cawthorh, near Doncaster; W. Wrightson, Esq. An elegant mansion, in one of the finest situations in the kingdom. The grounds are extensive, containing in the park a Gothic mansion, and the kitchen-garden, and are, generally speaking, well planted.

Cawthorh Park,—near Doncaster; Geo. Wrightson, Esq. A large estate, and the mansion contiguous to it, extensive, and in a beautiful spot.

Cumnor Hall,—near Oxford; W. M. Wilson, Esq. A country house with a conical mound in front woodeed to the top, and curving, from the latter, to a fine tower, by the hands of a skilful gardener. There is a good collection of bog-plants for which the cold, on the matted climate of this place is well adapted.

Eastnor Park,—near Hereford; Geo. Holt, Esq. A curious and elegant shooting-coatting, surrounded with sports, and extensive walks.

Eynsham,—near Hertford; Sir H. C. Hutton. A noble structure, commanding fine views of the Vale of Wharfe.

Everingham,—near Market Wrigthton; M. Contant, Esq. A large and commodious residence, on a flat country; that has with a successful imitation of a river.

 Eston Hall,—near Eston; Geo. W. M. Wilson, Esq. A country house with a conical mound in front wooded to the top, and curving, from the latter, to a fine tower, by the hands of a skilful gardener. There is a good collection of bog-plants for which the cold, on the matted climate of this place is well adapted.

Eyesnor Park,—near Nottingham; Geo. Holt, Esq. A curious and elegant shooting-coatting, surrounded with sports, and extensive walks.

Farnby Hall,—near Osby; W. Fawkes, Esq. An elegant mansion, in the manner of the Ionic order, with extensive views of the bank opposite, across the Vale of Wharfe. The kitchen-garden and farm well attended.

Gisburn,—near Gisburn; Geo. Wilson, Esq. A large and commodious residence, on the side of a hill, commanding extensive views of the bank opposite, across the Vale of Wharfe. The kitchen-garden and farm well attended.

Hackfall,—near Uppon; Geo. Wilson, Esq. A large and commodious residence, on a slope of a steep rocky declivity, descending to a woody glen; the water descends along the declivity, showing finely varied views, a cascade, and a number of other curious features. The grounds contain a number of sufficiently rare and curious plants, and in particular are the common old pine trees (P. sylvestre) and a good kitchen-garden.

Wentworth Park,—near Barnsley; H. Vernon, Esq. An extensive flat-countrie, containing a piece of water, half-way down the slope of the hill, rising to the top of the grounds, and to the left of which light to another strange and unnatural effect. Near the latter is the most magnificent arbor of the true geometric style, and contains some fine cedars and other exotics, a Fragrant and large.

Whitley Hall,—near Doncaster; Sir Will. Cooke, Bart. On the banks of the Don, in a low but beautiful situation, and decorous with some of the finest oak's in the country.
758. First-rate residences.

Castle Howard, near Malton; Earl of Carlisle. A magnificent palace, with a front of greater extent than that of Blenheim; the grounds not favored by nature, but contain a large piece of water, and are considerably enlarged and improved by the present earl. There are several ornamental buildings in the grounds, and especially a surprising mausoleum.

York, near Helmsley; C. S. Duncombe, Esq. A splendid new mansion, containing various embellishments and decays for gardens.

Heaton Hall, near Hibbrough; G. Pyke, Esq. The house was modernised in 1805, and stands in a large park, finely disposed into pleasure-grounds.

Bramham Hall, near Helmsley; Rev. Sam. Raymo. A spacious mansion, fine terrace, and beautiful lawn.

Brockholes Lodge, near Kirkby; F. Du Cane, Esq. A handsome mansion, pleasantly situated on an eminence, near the centre of a fine park, containing fine views.

Burnbrough Hall, near Merrington; R. Salvin, Esq. A low, re- chue, and much improved spot.

Camphill, near Newcastle; J. E. Edg, Esq. A steeple of a rock; near Watergate; R. Burdon, Esq. A handsome cascading waterfall, on the top of a woody precipice, which descends to a romantic dell.

Ox Close Hall, near Batterby; W. Salvin, Esq. The house occupies a lovely situation on the banks of the Tees, surrounded by plantations, enclosing a garden noted for its botanical collection.

RGrange Hall, near Darlington; G. Allans, Esq. A modern mansion, containing a collection of natural history.

Granville, near Lancaster; Sir T. Clavers. A plain but large mansion; and pleasant grounds, ornamented with buildings and plantations.

Northallerton; near Darlington; Sir T. Liddell. A plain mansion, surrounded by plantations, and containing fine views.

Northallerton; near Wakefield; J. Bland, Esq. A modern mansion, sheltered by a fine forest of oaks and elms; close by a cascade, and good house, surrounded by a beautiful amphitheatrical setting of hugging woods.

Shay House, near Winsdon; Harrison, Esq. A residence for pleasing grandeur, containing great planting.

Shandy Hall, near Greatham; Sir H. V. Tempest. An elegant residence, combining hospitalite comforts, and an attractive mixture of varied ground, woods, and water.

Templeton Hall, near Lancaster; T. White, Esq. Son and successor to the eminent landscape-gardener of the name. A small mansion, and extensive plantations on a dreary and bleak moor, now rendered beautiful, comfortable, and valuable.

759. The following are first-rate residences:—

Gibside, near Darlington; John Stratton. A noble mansion is situated on the east side of the Derwent; the park is four miles in circumference, much varied in surface, and well clothed with timber. The old oak walks are very extensive.

Newton Hall, near Newcastle; B. Priestman. An elegant green house, in the brink of a wooded glen; the banqueting-house; the Ionic column of 120 feet, crowned with a statue of liberty, the terrace, and chapel, are much admired.

Hardwick, near Hedgedge; M. Russel, Esq. Created from bog by the former proprietor, J. Bandon, Esq., and now celebrated for the beauty of its pleasure-grounds and the elegance of its buildings. The gardens were commenced in 1750. The terrace, the bathing-house, the lake, the winding-fountain, the cascade, the lakes, the rivers, and the banqueting-house, are much admired.

Lamington Hall, near Chatsworth; C. A. Lambton, Esq. A modern building by Honson; and now a very much improved place. The Most of gardens containing a great extent of hot-houses.

Lamport Castle, near Chirk; Sir M. Vanburgh; Earl of Scarbrough. The mansion is a quadrangle of the area of Edward I. placed on the brow of a hill. At the north angle is an octagon turret, machicolated for the purpose of snaring as-sailants, and in different parts are other arrangements of a former age, to be seen in the execution of natural history.

Old Hall, near Newcastle; Sir M. Lumley, Bt. A noble Gothic pile, on an elevated rocky foundation. It affords a fine example of magnificence and comfort in the large entrance-hall, into which carriage-drives before the visitors are set down. The park, plantations, and terraces, are laid out with much dignity of the castle. There is a terrace, commanding extensive perspectives, 720 foot in length, 200 foot in breadth, and highly cultivated; the farmyard is close to the castle, and excluded from the prospect; the saloons and chambers are splendidly furnished, and stables are rendered interesting architectural piles, and on the whole, few places in the empire are so magnificent, so complete, and so desirable.

Sellaby Hall, near Selby; Earl of Darlington. A free- stone and timbered house, near a ground-hill, surrounded by a most great taste and judgment; the stables are arranged so as to form an ornament and continuation to the house, and the effect of the whole highly beautiful.

758. NORTHUMBERLAND. A surface of 1,157,790 acres, much varied by hills and mountains; fertile and well cultivated in the valleys, and abounding in ruined castles. Hexham is noted for the grandeur of its ruins at Gateshead and in the Tyne; the estate, however, on the Durham side of the Tyne, carried on by Falla and Son, and at Morpeth. Brown, the celebrated landscape-gardener, was born at Cambol, or Camphill, near Hartburn, in this county.

Rabyhurst, near Roxton; the Hon. J. B. Simpson. A comfortable residence; the pleasure-gounds laid out in good style by H. Repton.

Caldeby Castle, near Warb. J. Reed, Esq. A delightful residence, containing great water, woods, and water, all respecting enchanting.

Stanhope, near Newcastle; C. J. Brandling, Esq. A mansion by Pain, and the grounds surrounded by a broad belt of well-varietyed vines on clumps, and a piece of water by White.

Hutton Hall, near Newcastle; M. W. Ridley. An elegant house by Newton, the treasurer of Virginia, erected in 1715, on the steep and woody banks of Ouseburn. House Beautiful, near Warkworth; W. Ord, Esq. The house surrounded by high and bold rocks, and hanging woods which, with the lawn, being in high keeping, forms the finest spot.

757. First-rate residences.

Alnwick Castle, near Alnwick; Duke of Northumberland. A noble and extensive castle, with good large house, near the sea, which has been lately much improved.

Alnwick Botanical Garden was established by subscription, and opened to the public in the year 1805, and has continued open ever since. It contains upwards of five acres, a great quantity of the finest specimens of flower and shrub garden, and is admirably arranged and disposed. It contains the great greenhouse, and has lately been improved by the addition of another greenhouse, extending to about 200 feet in length, 30 feet in width, 12 feet in height, and containing a fine collection of flowers; and to whose industry, and extensive correspondence, the garden owes, in a great part, its present flourishing condition.

Florists' Gardens. The principal of those exclusively devoted to the culture of the flower-garden, are those at Kew and Hore's, both of Botton. Taylor and Smith are extensive florists at Manchester, and compose also the nursery business. Buchanan, at Manchester, is a florist, and has been for many years of good standing; and there are above half a dozen very good florists at Galston.

Allington Hall, near Chorley; Sir R. Clayton. A noble mansion, containing fine garden, wrought up in wood; and the Shropshire, near Whalley; T. L. Parker, Esq. A large garden, with extensive pleasure grounds, and a house in the style of a castle. The garden is beautifully arranged, and contains an extensive greenhouse, and a fine collection of plants.
GARDENS OF CUMBRLAND.

large Elizabethan mansion, in a conspicuous situation; the park, the remains of an ancient forest, but rather neglected.

Dunickford Lodge,—near Ashton; lately P. D. Astley, Esq. A magnificent building, on a site of 150 acres, on a steep hill, with a broad terrace, and grounds particularly grand and picturesque.

Hudlow Hall,—near Little Milton; T. Wedder, Esq. A magnificent mansion, and grounds, remarkable for a summer-house built of unusual deal.

Huron Lodge,—near Manchester; Earl Wilton. A handsome garden, with a racecourse, and by the late Sir W. Sumner, in a commanding situation, in the midst of a fine park, five miles in circumference, and enclosed with a stone wall. The entrances-lodges in Duris, and mansion in the Ionic style.

Cloyd Hall,—near Warrington; Mrs. Hornby. The garden here was formerly rich in botany; and a catalogue of the plants was published by the gardener, Neale, in 1779.

Toodywell Hall,—near Byland; J. Townley, Esq. A large venerable structure, forming three sides of a quadrangle; the park, enclosed to Henry VIII.'s time, contains some very old elms, which, with the contiguous mountains and distant country, present various combinations of grand and picturesque scenery.

Croston Rectory,—near Ormskirk. About twenty years ago, here was a remarkable sale for a private gentleman, who trained them on a hot-bath, and by using the seed of successive years, the plants trained and in some measure accelerated. The plants were rooted under bell-glasses on a moderate hot-bed at the base of the wall, and trained up it like the love-apple.

Woofield. H. Suidel, Esq. near Blackburn. A handsome house, and an extensive park, well stocked with deer. A kitchen-garden, prolific in forced and exotic productions, and the rest of the garden under a separate arrangement.

Counrion Priory,—near Ambleside; T. Hendly, Esq. Chiefly remarkable for its abundant horticultural productions, hardy, forced, and exot.

GARDENS

1789. First-rate residences.

Ashdon Hall,—near Lancaster; Duke of Hamilton. An old baronial castle, in a park abounding with noble woods and fine marine views.

Knowsley Park,—near Prescot; Earl of Derby. An extensive park, and very extensive, with a lake, and fine mansion, attached to the present owner. The kitchen-gardens are extensive and well stocked with flowers, and near them is one of the loveliest views in England. The gardener here excels in growing cucumbers, which he produces at table every day in the year, from a small house, which he calls his cucumbers' house.

Brockenhurst House,—near Bremberugh; James Manconomic, Esq. The mansion is a large and handsome edifice of the old stone of the country, and the grounds are pleasant and picturesque out.

Booth's Hall,—near Knutsford; P. Leysh, Esq. The mansion is plain, the park extensive, and varied by some fine pieces of water.

Cardon,—near Farm; John Leech, Esq. The mansion is large and handsome, and the grounds are extensive and beautiful.

Crag Staining,—near Altrington; Earl Stamford. The mansion is a spacious brick quadrangle; and the park which surrounds it is extensive, and full of fine timber. Some of the trees, especially of the yew, have been under cultivation for many years.

Hali Hall,—near Ambleside; E. D. Astley, Esq. The mansion is in fine style, and the park extensive, and varied, and the pleasure grounds beautifully arranged.

Hush Hall,—near Hyde-Chapel; George Hyde Clark, Esq. The house ancient, and the grounds picturesque and elegant.

1792. WESTMORELAND.

A surface of 462,630 acres, and moors, that call aloud for planting and draining.

Colyghar, near Ambleside; T. Hunt. The residence of the Earl of Lonsdale, chiefly deserving notice for its extensive and judiciously managed plantations.

Bassenthwaite, near Keswick; R. J. Corbin, Esq. A Roman villa, with a dovecote, in the centre of a small island, well stocked with deer and pheasants, is the western prospect, and those of the lakes, are the designs of the late T. White, Esq. the landscape-gardener of the north.

Loweswater Castle,—near Loweswater; Lord Loudesdale. A first-rate residence, the mansion elevated by Simmler, of Rosettes, near Pateley, with an outer and inner court, and a terrace as a basement 500 feet long and 100 feet wide; the whole building rather low, and in the style of the ancient Elizabethan period.

The parks and pleasure-grounds are of great extent, and command a variety of prospects and scenery, not surpassed in any other part of the British dominions. There is a terrace of closely mown turf: the grasses of the first mountain kind. It is nearly a mile in length, and runs along the brink of a lime-snow cliff, which overhangs a great part of the park, irregularly scattered with forest trees of immense growth, and well stocked with deer. It was this park that Lord Macartney compared to the garden of the Emperor of China at Canton, with which it was said to far exceed it.

Rogery Hall,—near Kendal; Rev. T. Fleming. On the banks of Wansumerdale; and said to resemble Furnesy, the celebrated seat of Valburne, near Geneva.

Rydal Hall (Bee-dale),—near Kendal; Sir P. Le Fleming. A romantic seat on a mountain side, clothed with natural oak woods, and celebrated for its waterfall.

Warton; —near Carlisle; J. J. White. The garden is extensive, and contains 5000 acres, including a mere, or lake, of some extent; the kitchen-garden is large, and contains a spacious well constructed pynery, and shady border for roses.

Tutton Park,—near Knutsford; W. Egerton, Esq. The house is from an elegant design of Wyatt; the park contains 5000 acres, including a mere, or lake, of some extent; the kitchen-garden is large, and contains a spacious well constructed pynery, and shady border for roses.

1793. CUMBRLAND.

A surface of 970,000 acres, entirely mountainous, and abounding in lakes, the most numerous and celebrated of any county in the empire: as in the other north-western counties, the climate is severe, and winter long.

Muncaster Castle,—near Carlisle; Henry Howard, Esq. The mansion has lately been improved from the designs of Nicholas Hawksmoor; it is boldly situated on the banks of the Eden, which are well wooded by nature, and singularly grand and picturesque. The grandfather of the present owner began

Hot-house or pit, with a vault underneath, the first which was heated by steam in England.

The grounds were laid out by Wedder, and are said to have been laid out by Mottet, James II.'s gardener, for the Sciffril family, successors from Edward II.'s time till within the eighteenth century.

The mansion has lately been improved from the designs of Nicholas Hawksmoor; it is boldly situated on the banks of the Eden, which are well wooded by nature, and singularly grand and picturesque. The grandfather of the present owner began to lead walks through these gardens in 1706, and is said to have been one of the first persons who broke through the trammles of the ancient style of laying out grounds. The late Mr. Meikle, who was a good deal employed to lay out grounds in the north of England, was originally gardener here.
7904. HAMPSHIRE. A surface of 1,115,000 acres, considerably varied in character of surface, yet without high hills. The Isle of Wight is a detached portion, remarkable for its beauty and fertility; the Downs, a chalky ridge, are bare of timber. The New Forest and Bere Forest occupy large tracts near Southampton, and the principal wood in the county is the New Forest, which is managed by a regular vigneron. At Fratton, near Portsmouth, is grown the Portsmouth broccoli, so much esteemed.

7905. WILTSHIRE. A surface of 281,150 acres; elevated, varied, but not much wooded: the climate dry and cold. Gary and Moody, nurserymen, near Salisbury, grow the best cressougies in England, of which they send large quantities annually to Manchester, and other parts; there is a famous grower of rose hips and anemonies at Marlborough, besides various market-gardens. Savernake Forest, in Totton Park, is the only one in the kingdom belonging to a subject.

7906. MONKASTR HOUSE. — near Ragley; Lord Muncaster. Great improvements have been made by planting the bleak hills on this estate: his lordship has also irrigated extensively, and is the most successful agriculturist. Nunnery, — near Pershich; Mr. Bamby, Esq. The house is situated on a very pleasing situation, extremely beautiful, and laid out with great taste and judgment. They lay out the Park of this estate, whose grounds produce several cascades and one waterfall of nearly twelve feet.

Penony Hall, — near Ermeston; G. G. Stankey, Esq. The house is modern and surrounded by numerous plantations and agricultural improvements made by the present owner, Sir A. A. Stankey, Bt.

x. Workington Hall, — near Whitehaven; J. C. Curwen, Esq. The house is an commodious residence near St. Lawrence, and the park and pleasure-grounds are extensive, and the house itself, a companion to the residence of the Earl of Curwen and Curwen with Hallam and Coke, Wolberdon and Bedford.

1082. STATISTICS OF GARDENING.
Earl's Stile.—Connected with this spot is a rustic village by design. It consists of several cottages placed on the sides of the road, whose roofs are reached which is surrounded by an orchard and is the terror of the gardeners, trees, flower-beds, &c. It is not an abode, but a place of retirement. A respectable, and truly picturesque edifice, with bay windows, gables, new-hedges, terraces, &c. in the genuine style of the last century.

Lilford Park.—near Wootton Bassett: Lord Bolingbroke. It is abounding in curious for its old, and now abounding in place, and the noblest, and was for many years a fine pond of water.

Layard House.—near Salisbury; Earl of Radnor. A house remarkable for its ground-plan, which was intended to resemble that of the 'Temple of Peace,' erected about 1591, from the designs of John Thorne. An entirely new plan, in the castellated style, is in contemplation. The garden is a mass of woods and trees, laid out by the Avon.

Malton Parks.—near Ramburgh; Esq. and E. Popham, Esq. Four miles in circumference, well wooded, and containing a hill, and a well-pleased view of the sea, is from this country, and laid out 1730.

Malbecket Park.—near Dawton; J. Osborne, Esq. The grounds remarkable for a beautiful Hindu temple, erected by the late Mr. John M'Culloch, Esq. The site recommended by thespecifications of which is abounding in flowers and trees, are formed of the most choice sorts of roses and American plants, and are laid out at great expense, and afterwards left to run wild. There is a noble new edifice, and a large grotto which have a most delightful effect. Herbaceous plants are equally profligate, and there are a few seats and buildings, but these are chiefly confined to the lower grounds, where there are several large pieces of water, cascades, grottoes, &c. near to the site of the former Grecian mansion. This we were fortunate enough to see before its removal in 1806. The kitchen-garden is good, and no expense spared to render it productive in exult as well as hardy exults and fruits.

Marlcombe.—near W. J. Smith, Esq. A house and office, with a front of 550 feet, on the summit of an eminence, surrounded by a well wooded and watered park, in which the scenery is diversified. The house is large and splendid, and contains a rivulet, the waters of which form several cascades. On the whole, the romantic mansion, with its ancient demesne, presents a lawn, hill, vales, woods, and diversified plantations.

Methuen Park.—near Merton; C. Hoare, Esq. The mansion from the designs of Coln Campbell, author of the Vitruvius Britannicus: the grounds long noted for their sylvan beauties and picturesque scenes. The seventeenth century mansion, in the manner of Inigo Jones, with its long terraced gardens, and deep narrow valleys with rivulets. The sides and surfaces of some of the terraces are thickly, and others partially, clothed with wood. One of the vallies is covered with water by means of a dam, and various cascades are formed on the brooks: throughout the whole place, temples, obelisks, bridges, covered seats, and other buildings are diversified.

Wardour Castle.—near Salisbury; Earl Arundel. A large mansion, surrounded by a well wooded and watered park, diversified in surface and by planting, and they contain the famed ruins of an old castle.

Willow.—near Wilton; Earl Pembroke. An extensive pile, of rather incongruous architecture, by Himbleton, and now enclosed in one of the finest situations in the county. The park contains some ornamental buildings, and Grove House, and in the close, is ancient, and the later Victorian taste.

Thurlestone, Devonshire. A surface of 750 acres, divided into two parts by a range of chalk hills, which run east and west: the climate dry and healthy, and the soil rich. Near this county is the Isle of Wight, Jersey, which, with Guernsey, supply roots of the amaryllis sannensii to the seedsmen, and some grapes to the fruiters. Petrarch is grown to a great extent, and here is a show of figs, bunches, &c., which form an excellent coast station in acclimatizing the plants of hot countries. The arum maculatum is so abundant in the Isle of Portland, that the common people send the rootlets of these plants, prepare them as sago, and

Gardens and Rev. late Sir John England, 112 acres, is a splendid modern mansion, and extensive and beautifully varied ground. The gardens in a high state of cultivation, and are varied with trees, flowers, and with great taste. In this estate, in 1725, was found a mushroom that may be estimated at 400 pounds in weight, was eight deep, and the section almost in the form of the figure 8. This was erected 1657, and is large and substantial. The kitchen-garden is well attended, and the park-scenery is extensive.

Lillworth Castle.—near Lillworth; T. Wilth, Esq. The house is a modern mansion, in the close, and is handsome and large, and has lately been much improved.

Wilton Abbey.—near Wilton; Sir John England. The grounds of this place are one of the finest residences in the county.

Kilmarnock.—near Kilmarnock; William Morton Pitt, Esq. The situation is most picturesque, and is a fine ground, but of lowly growth, is covered with woods, some of which are of ancient growth, but the ground is mostly covered with open and richly wooded.

Dorsetshire. A surface of 750,000 acres, divided into two parts by a range of chalk hills, which run east and west: the climate dry and healthy, and the soil rich. Near this county is the Isle of Wight, Jersey, which, with Guernsey, supply roots of the amaryllis sannensii to the seedsmen, and some grapes to the fruiters. Petrarch is grown to a great extent, and here is a show of figs, bunches, &c., which form an excellent coast station in acclimatizing the plants of hot countries. The arum maculatum is so abundant in the Isle of Portland, that the common people send the rootlets of these plants, prepare them as sago, and

From the apex of a hill, amidst a grove of ancient pines, rises the lofty tower, turrets, pediments, and pinacules of a mansion, which is surrounded by the picturesque scenery of an extensive, well wooded, and diversified park. A noble temple, raised on a pedestal, with a colonnade, in the Roman style, is an additional ornament. It consists of a central tower about 70 feet in height, with an arched entrance, supported by four columns, in the Roman style, opening from the tower to the east, and two wings, branching out from the north and south. The whole is surrounded by a park, the greater part of which is laid out into gardens, galleries, libraries, eating-rooms, parlours, drawing-rooms, &c. are fitted up; and at the same time there is a great attention to the choicest works in literature and the fine arts. The architecture of the house is of the best Roman schools, and the results of the most eminent artists of the country were employed in finishing the interior.

The Abbey is approached by a broad avenue of turf, upwards of a mile in length, on the summit of a ridge, the sides of which are enclosed by a noble range of trees: a noble seat is surrounded by a park, which is laid out into pleasure-grounds, and the whole is surrounded by a park, the greater part of which is laid out into gardens, galleries, libraries, eating-rooms, parlours, drawing-rooms, &c. are fitted up; and at the same time there is a great attention to the choicest works in literature and the fine arts. The architecture of the house is of the best Roman schools, and the results of the most eminent artists of the country were employed in finishing the interior.

The architecture of the house is of the best Roman schools, and the results of the most eminent artists of the country were employed in finishing the interior.
Enmore Castle, near Enmore; Sir Edm. Egmont. A quadrangular embattled structure, the stables and offices all under ground; the shrubbery next the garden is well arranged, and the views over a finely cultivated and enclosed country.

7600. Devonshire. A surface of 1,600,000 acres, abounding in mountains, hills, and valleys; the formation is varied, and the views over a finely cultivated and enclosed country.

Mount Edgecombe, near Plymouth; Earl Mount Edgecombe. The house is a very ancient building; the grounds are among the most remarkable in England, fine trees, pastures, and meadows, have been improved by the present earl, and an account of them lately published, entitled A Walk round Mount Edgecombe, with eight views.

Nudwell, near Topsham; Lord Heathfield. The mansion is large, and the park scenery fine.

Mount Edgecombe, near Plymouth; Earl Mount Edgecombe. The house is a very ancient building; the grounds are among the most remarkable in England, fine trees, pastures, and meadows, have been improved by the present earl, and an account of them lately published, entitled A Walk round Mount Edgecombe, with eight views.

Nudwell, near Topsham; Lord Heathfield. The mansion is large, and the park scenery fine.
**GARDENS OF WALES.**

7003. ANGLESEA, or MONA. A hilly bleak island of 500,000 acres; ill adapted for any branch of gardening, but containing a few seats worthy of notice.

Boron Hill, near Beaumaris; Lord Bulkeley. A house implying a combination of different situations, and beautifully situated on a mountain-top; contains, to the knowledge of the present owner, 140 acres of gardens, extending from the house in every direction, divided into the several basins of different size and extent, and terminated by formal gardeners to the banks of the Menai; Marquis of Anglesey.

Pentregafort Castle, near Bangor; Lady Penrhyn. A castle, the situation of which seems improved by Lt. Col. Wy Wyatt, surrounded by plantations, for the extent of which and

7005. DENBIGHSHIRE. A hilly tract of 410,000 acres, the soil various, but not rich or favourable for cultivation, excepting in the valleys. The seats are chiefly on the Chester side of the river.

Llanelly Hall, near Denbigh; M. Hughes, Esq. Situated on a flat lawn, with a beechery too near, and not properly planted out.

Pendre Farm, near Denbigh; Mrs. Lloyd. A farm house, handsomely laid out and kept in good order.

Pond Park, near Ruthin; Lord Bagot. Delightfully situated, and finely wooded with old chestnut-trees.

Plas Newydd, near Llangollen; Lady Eleanor Butler, and Miss Fanshaw. An elegant residence fitted up in the cottage style, and the grounds beautifully laid out by the elegant and accomplished proprietors.

Trefechen Hall, near Llangollen; T. Jones, Esq. A handsome structure of brick, in a flat situation, with a park consisting of 130 acres of bottom land, and a fine seat.

Bryn Hall, near Wrexham; S. Yorke, Esq. Chiefly remarkable for the beauty of the approach through a dense wood; there are also other unbridged walks, a rivulet, lawn, and delightful pleasure-ground, with a splendid rock-pile, containing ancient and beautiful trees.

Brefach Hall, near St. Asaph; Sir T. Hammer. A handsome brick structure, situated in grounds naturally fine from the situation, and containing several extensive and picturesque terraces.

Heath Hall, near Mold; G. L. V. Esq. Erected about ten years ago, on a magnificent site, with three frontages, and a surface of 50,000 acres, with new gardens of any

7006. FLINTSHIRE. A surface of 160,000 acres, counties, and not unfavourable to gardening.

Widred Hall, near Whitford; R. Pennington. A mansion 1-shaped, with Gothic wings, in a low sequestered situation, surrounded by finely wooded grounds, which are tastefully laid out, by the late eminent naturalist, father of the present proprietor.

Rhyd-y-Groes Hall, near St. Asaph; Sir T. Hammer. A handsome brick structure, situated in grounds naturally fine from the situation, and containing several extensive and picturesque terraces.

Berry Hall, near Wrexham; Sir F. Culliford. A good mansion, on an elevated lawn; the grounds extended, and greatly improved by the present proprietor.

7007. CARDIGANSHIRE. A surface of 500,400 acres, the mountains generally bleak and bare of wood.

Hafod, near Aberystwyth; Lord Bute. Long one of the grandest and most interesting of any residence in either North or South Wales.

The house, in a peculiar style of Gothic or Moorish architecture, in the midst of a valley, is surrounded by masses of trees, and other natural productions, which, in connection with the surface, is the most beautiful and picturesque spot in the principality, and in which the system of the gentlemen is to solemnise the beauty of nature, without excessive care or expense, in such a manner that the eye is kept continually in motion, and is always looking for something new.

There are also many beautiful gardens, which are embellished with woods and plantations, and a lake of 50 acres, and a variety of trees and shrubs, cut and planted in the most beautiful manner, with a great deal of attention to the formation of picturesque walks, and the arrangement of the grounds, in such a manner that the eye is continually in motion, and is always looking for something new.

7008. GLAMORGANSHIRE. A surface of 22,000 acres, mountainous, more than any in South Wales;

Cardiff Castle, near Neath; — Grant, Esq. The house rises with a noble portico and grandeur, on the top of a hill, overlooking the town and adjacent country. The grounds are laid out with great taste, and the estate is admirably situated.

Llandough, near Cowbridge; Sir J. Aubrey, an Elkington. An elegant seat, with many beautiful walks and plantations, and a great deal of attention paid to the surrounding scenery and walks.

Margam, near Margam; — Talbot, Esq. The house, on a hill, overlooking the valley, is surrounded by woods and plantations, and a lake.

Pencroft, near Bridgend; — Wyndham, Esq. The house, on a hill, overlooking the valley, is surrounded by woods and plantations, and a lake.

7009. PEMBROKESHIRE. A peninsular surface of 335,000 acres; generally plain and fertile. Grapes and fruit-orchards are numerous, the hot-houses of the county, which are well attended, and the wine-gardens of the town, are on the sea-coast, where the climate is peculiarly favourable for such productions.

Castle Madoc, near St. Dogmaels; — Hanmer, Esq. The house is a noble seat, with extensive grounds, and a lake.

Llandeilo, near Milford; H. Bartow, Esq. A pleasantly situated house, the grounds bordered by a creek on one side, and Milford-haven on the other.

On the other side, the grounds are extensive, and the house is situated on a hill, overlooking the sea.

Sir William, near St. Dogmaels; — Saunders, Esq. The house is a noble seat, on the sea-coast, and the grounds are extensive, and the house is situated on a hill, overlooking the sea.

7100. RADNORSHIRE. A surface of 262,400 acres; partly level and partly mountainous.

Bodiolbrooke, near Presteigne; Sir H. Jones. Mentioned as worthy of notice.

X Stackpole Court, near Pembroke; Lord Cawdor. A grand and imposing building, situated on the precipitous shore of the smiling valley, which is dotted with cultivated fields, and surrounded by a lake. Along the front next the water, a broad terrace has been formed; and the other, which contains the entrance, looks extremely fine. The grounds are extensive, and the house is most successfully cultivated by Buchan, who, in 1821, at 20 to 20,000 cwt. of turnips, and 170 cwt. of grapes.

Pentre, near St. Dogmaels; — Saunders, Esq. The house is a noble seat, on the sea-coast, and the grounds are extensive, and the house is situated on a hill, overlooking the sea. The gardens in the old style carefully kept up, the whole greatly admired.

7101. ANGLESEA, or MONA. A hilly bleak island of 500,000 acres; ill adapted for any branch of gardening, but containing a few seats worthy of notice. Baron Hill, near Beaumaris; Lord Bulkeley. A house implying a combination of different situations, and beautifully situated on a mountain-top; contains, to the knowledge of the present owner, 140 acres of gardens, extending from the house in every direction, divided into the several basins of different size and extent, and terminated by formal gardeners to the banks of the Menai; Marquis of Anglesey.

Pentregafort Castle, near Bangor; Lady Penrhyn. A castle, the situation of which seems improved by Lt. Col. Wy Wyatt, surrounded by plantations, for the extent of which and
Welford House, near Wootton. A good modern house; the grounds contain some flourishing young plantations.

7011. MONTGOMERYSHIRE. A surface of 500,000 acres; generally mountainous, but verdant, fertile, and wooded. Some of the vales are residences.

N. Bowen Hall, near Newtown; Sir John Prise. A finely wooded park of considerable extent.

The garden of Lord Linlithgow, Esq. A good mansion, and the grounds greatly improved by the late owner, who was the greatest planter in the county, having planted 60 acres of red sandstone on the edge of a rock, the entrance by an ancient gateway, between two mossy circular towers. The ascent by two lime-hedge terraces rising one above another, connected by steps, and ornamented with statues, vases, and other antique remains. There were hanging gardens, in imitation of those of St. Germaines, composed of a series of oval beds, connected by flights of steps leading to the solid rock, with water-works, &c.; but these are now altered, or, like every thing else here, going rapidly to decay. The park is much varied by nature, and combines turf as smooth, close, and green, as the finest lawn, broken with broken ground, rock, and rough thickets of thorns and oaks. It contained much old timber, but great part of this has been lately felled.

7012. MERIONETHSHIRE. A much-adored and romantic surface of 500,000 acres; abounding in streams, rocks, and ruined castles; but with few residences of wealthy proprietors, and consequently little display of gardening.

Nannau, near Dolgelly; Sir R. W. Vaughan. A substantial and elegant structure in a well wooded park, with fine prospects, and remarkable for a small herd of deer, which make venison of a superior flavor. There is a good kitchen-garden, but the present proprietor is chiefly devoted to agricultural pursuits, and is considered a good corn-farmer, and tolerable breeder.

Porth-y-Broch Hall, near Dolgelly; — Oakley, Esq. An elegant villa in a lawn, at the bottom of a hill, surrounded by pleasure grounds tastefully disposed, and containing a good kitchen-garden.

7013. BRECONSHIRE. A surface of 255,000 acres, entirely mountainous, with the exception of some of the narrow valleys; in general it is terra danna; as to every branch of gardening, excepting planting.

Cinderhain, near Merthyr Tydrell; William Crawshaw, Esq. The hot-house department of the kitchen-garden extensive, and the pine-apple extensively and successfully cultivated.

Dyffryn House; near Cwmcarn; — E. C. Williams, Esq. A good house, with a meadow and some rising grounds formed into an extensive park, believed by the Usk. The kitchen-garden contains some substantial cast-iron hot-houses.

Llangard Castle, near Builth; J. Macnamara, Esq. A new manor commenced, and other improvements in progress. According to Nalkin (Scenery of South Wales, &c., 251.), this place may, and probably will, be one of the first in Wales.

Penpont House, near Brecknock; P. Williams, Esq. A respectable mansion, with a finely wooded park, watered by the Usk.

7014. CAERMARTHENSHIRE. A surface of 228,000 acres; fruitful in corn and grass, and the least hilly of any county in South Wales.

Heulog Castle, near Landover; Col. Williams. The grounds occupy both sides of the river Towy, and are connected by a foot-bridge, raised upon two projecting rocks, and of a construction that combines with the wild and romantic character of the scene.

Aberavon, near Llandeilo; Admiral Poley. A modern house in a small park, but which contains some good trees and shrubs.

Edinford, near Llandeilo; Sir J. H. Williams. The mansion and grounds exhibit an appearance of magnificence, and contain a lofty avenue, which serves as an approach.

Talylaria, near Llandeilo; Lord R. Seymour. Low, flat ground, but well wooded.

Newton House, near Llandeilo; Lord Dynevor. A plain square building, with a small turret surmounting each angle, in a park comprising a considerable extent of ground, and exhibiting, perhaps, a richer display of picturesque beauty than any spot of equal size in the kingdom. The scene is finely described by Dyer in his poem of Grange Hill:

"Gaudy as the opening dawn
Lies a long and level lawn,"

Golden Grove, near Llandilo; Lord Caviller. An indifferent house on low grounds, lately begun to be planted and improved. The kitchen-garden and hot-houses are extensive, and well attended to.

Middleton Hall, near Llandilo; Sir W. Paxton. One of the most splendid seats near Llandilo; the grounds finely planted, and containing an elegant prospect-tower, and a good kitchen-garden.

Sect. III. Scotland.

7015. The surface of Scotland is estimated at 18,944,000 acres, in three natural divisions. The first lies north of the chain of Highland lakes, which stretch from Murray to Mull, and consists of little else but dreary mountains and some moors; the second, or middle division, extends from this chain of lakes to the rivers Forth and Clyde; it is mountainous, but cultivated in the valleys and on the eastern shore to a considerable extent; the remaining division is covered by hills with some mountains, but everywhere cultivated or improvable, and highly favorable for most branches of gardening.

The country-residences of Scotland are almost entirely confined to the two last divisions; in general they excel those of England in the prominence of their natural features, being generally backed by hills or mountains; encompassed by a river or stream; or situated on a lake, or the sea-shore. But they are inferior to those of the south in magnificence, and even in taste, both as to architecture and landscape-gardening. The gardeners of Scotland have long been in esteem for skill and assiduity in their profession; they excel in the culture and general management of the kitchen-garden, those of a certain rank, as Neilh has observed, being generally kept in much better order; and at less expense than gardens of the same kind and rank in England.

7016. The garden-productions in which Scotland excels are, turnips, potatoes, strawberries, raspberries, and gooseberries. In fruits, Scotland does not excel, nor can this be the case till the practice of producing a better be more common among the ordinary gentry of the country than it is, or was ten years ago. A dessert is rare among the middling classes; and fruit pies or cider are quite unknown to the operative inhabitants.

The most extraordinary gardening exertions which have been made in Scotland are in the planting department, and chiefly in the middle division of the country, which already begins to assume a new and sylvan character. The cottage-gardens are generally carefully cropped with the more common vegetables, and form a useful appendage to the labours' dwelling. The farmers' gardens are rather neglected.
7617. The principal commercial gardens lie around the capital; taken altogether they occupy about 590 acres, of which 130 are employed as nursery grounds by seven or eight individuals, who hold from fifty to four acres each. The four hundred acres of market-garden-ground are cultivated by nearly eighty gardeners, in holdings of from half an acre to about twenty acres each. There are market-gardens in almost every county, and the total extent of ground occupied as nurseries in the kingdom is estimated at 700 acres. Some of these nurseries raise and dispose annually of ten or twelve millions of seedlings and transplanted forest trees. Previous to 1760, when the taste for planting and rural embellishment in Scotland began to increase, there were not above six nurseries in Scotland; and these, taken together, did not occupy above sixty or seventy acres. In 1812, one house in Edinburgh shipped upwards of two million of seedlings, chiefly harch and spae fir; Scotch pine, birch, elm, ash, alder, and hawthorns. 7618. MIDLOTHIAN. A surrace of 230,400 acres, varied by inequalities, and in some places by hills; Edinburgh, and the seats of other lords and gentlemen, are surrounded by small urban gardens, three extensive nurseries, and a botanic garden. The nursery in Midlothian, which also the Caledonian Gardener's Lodge, is held in the capital. There is a market for culinary productions and the common fruits; and it is in contemplation to establish one for ornamental plants in pots and flowers. 7619. Publick Promenade. — Holyrood Park is a piece of ground of moderate extent, adjoining the palace of Holyrood. The hill or park is divided with fruit from the standard trees, on the uplands of 400 species of plants, and a great variety of mineral springs, with varied and extensive views and prospects. (See 7371.) The Edinburgh Botanic Garden, as it existed till lately, consisted of extensive Catherine's woods, chiefly situated on the north of the road which leads past it. It was derelict for nearly one hundred years, from its original to its late site under the auspices of Dr. Hope in 1867, and is now (1883) removing to a more extensive area, surrounding the present house of the garden, and his able garden-curator, Mr. Naughton. This site contains 16 acres. It is now under the auspices of the Edinburgh and Lander Philosophical Society, and the Edinburgh and Leith Philosophical Society. 7620. Great Gardens. — Of any extent, are known to have existed previously to 1746. At that time Henry Prize cultivated pot, potatoes, turnips, and other culinary articles, on an extensive scale: before his time, the supply was limited to what could be carried in baskets. Next to Princes Street, Peacock may be mentioned as an ex- gower about 1750; and his successor, who now occupies about twenty acres, produces at this time the best asparagus, cauliflower, and celery, sent to market. Rose's garden is about the same extent; the rest are considerably smaller. Henry Prize and the gardens of the four seasons, with standard fruit-trees; and since the custom of making British wines from foreign grapes, and the cultivation of the grape at the northern extremity of the country has increased, a few acres are occupied by crape, gooseberries, and rasp- berries, and the rest is given to general perfection than probably anywhere else in Britain, at Kirkaldy, on the banks of the Firth of Forth. 7621. Orchards. — There are but few of these in this county, and those are chiefly near Lawsdane and Dalkeith. Edinburgh market is supplied with fruit from the standard trees, on the market-gardens, and from such private gardens as are let to common gardeners. These gardens are chiefly divided into small strips, and produces the best early grapes. 7622. Small Gardens. — For the cultivation of flowers, and ornamental shrubs, there are small gardens in many places, especially near Edinburgh and Mid-Calder. 7623. The Leith Walk Nursery. — Means. Dickson and Shanksley, a respectable establishment of nearly fifty years' standing, in which every description of nursery article is propagated according to the demand, and the whole kept in excellent order and neatness. 7624. The Braughorn or Aispl桃園 Nursery (from Aispl, a brother). — Means. Dickson, brothers; an extensive establish- ment of nearly twenty years' standing, kept in good order. 7625. Small nurseries, judiciously managed. 7626. The Edinburgh or Mid-Calder Nursery. This establish- ment is conducted more on the plan of the London nurseries than any of the others. Flowers and tender exotics are cul- tivated on the site of the castle, or in the brand; grape and open garden, not covered either with mats or litter. They are divided into two compartments, or beds, in the sunny part called lazy beds of potato; but the details of the method the man shall be required to decline making public. 7627. There are some other nurseries, but not of sufficient note to require specifying particular in our very limited space. 7628. Near Mid-Calder: — Lawsdan Nursery, a stately fabric, surrounded with very extensive plantations. A vener- able, ancient house, the grounds, containing 500 acres, is in the possession of one of the best performing and strictest old style in the county, or perhaps in Scotland; with artistic 7629. EAST LOTHIAN. A surface of 190,308 acres, little varied on the east side, but hilly and mountainous towards the southern extremity. It is remarkable for the excellence of its agriculture; and it contains some good kitchen-gardens. There is a market in Edinburgh for two and three months of fresh fish for the supply of Edinburgh, and the shipping of Leith, and other sea-ports along the coast. There are small orchards at Ormiston and Prestonkirk. North Berwick House, — near North Berwick; Sir R. D. Ha- milton. A good house, surrounded by an extensive garden, closed by straight lines and strips, or double rows of trees in the ancient style; the object being to combine the general utility of a garden as a ground and pastures, with the utility and convenience of enclosures.
Wemyss House, — near Ayrshire; Earl of Wemyss. A magnificently proportioned mansion, in which all the chimneys are conducted to three stone domes, and issues by their slender columns, which are so proportioned as to require four fingers to hold the glasses placed between them, with only one window to each. It is situated close to the sea-shore, on level ground, laid out and planned by Ramsay; but there is not the least difficulty in quitting the house.

Ainsfield, — near Hatfield; Earl of Wemyss. A noble building, with a central tower from 150 feet long. The park is flat, and not extensive; but there is a large and excellent kitchen-garden.

Yester House, — near Yester; Marquess of Tweedale. An elegant and magnificent structure, with a park containing some of the finest trees and woods, planted in the last century, by a former earl, who wrote a treatise on Planting. It is also a remarkably fine holly-hedge of the same standing, and a good kitchen-garden. In 1806, pine-apples were grown here in a pit, with a brick vault below, into which they were introduced. Some of the plants were in pots, and the rest planted in the soil.

Salton Hall, — near Salton; Sir John Agnew, Esq. A good kitchen-garden, and well planted pleasure-grounds.

760. BERWICKSHIRE. A surface of 326,400 acres, of which 79,000 are pasturage. The northern part mountainous, with few country-scots: but the southern and eastern districts gently varied in surface; rich in soil in some places; and everywhere under a system of farming which has not been long established. In this part of the county are some gentlemen's scots, but none of any note.

Berwick, and near Dunse.

Dryburgh Abbey, — Plant'd by the Earl of Buchan in 1788, and now produce very fine pears and apples.

Duns Castle, — near Dunse; Hay, Esq. A respectable old place.

761. ROXBURGHSHIRE. A surface of 472,720 acres, chiefly hilly and mountainous, and in great part under pasture. There are a few acres of market-garden ground near Kelso and Jedburgh; and some orchards at these places, at Melrose, and at Gatton. At Jedburgh are pear-trees supposed to be from five to six centuries old. Some account of these orchards will be found in the Caledonian Horticulturists' Memoirs. (Vol. I., p. 25.)

Hawick and Haddington Nurseries. — Messrs. Dickson's extensive establishments, at the villages bearing these names, begun 1749, long the best in England and Scotland; and from them originated the Leith Walk Nursery, in Middle- thian, and the Perth nursery, in Perthshire.

At Greenlaw, the苹le and pear trees, planted by the priests of the abbey of these towns, in the 16th century, are still in a good state; and of these two principal kinds are called the duke's and mears pears.

Crailing House, — near Crailing; Paton, Esq. A neat place, most romantically situated on the high banks of the Jed.

762. SELKIRKSHIRE. A surface of 160,000 acres, of hills and mountains, almost entirely under pasture.

763. TWEDDALE. A surface of 299,778 acres, hilly and mountainous, generally in pasture; but with some barren moors and fertile vales. There is a nursery at Dumfries, and another at Dunoon.

764. DUMFRIESHIRE. A surface of 644,385 acres, consisting, in great part, of hills and mountains; but with some low fertile lands towards the south. There is a nursery at Dumfries, and about 100 acres of private orchard in this county, some of them a century old, and very productive. The greater part of the produce is sent to market.

765. KIRKBRIDGESHIRE. A surface of 561,641 acres, hilly, rocky, and with some mountains, the greater part in pasture. There are some market and fruit gardens along the coast, which send their produce to Dumfries and Ireland. An extensive orchard was formed by Lord Selkirk about 1789; and some of the best trees in most of the adjoining estates are calculated at 300 years of age.

Langham Cottage, — near Langham; Duke of Buccleuch. A picturesque heath-covered cottage, built as a temporary residence by the late duke, in a romantic situation, with beautiful pleasure-grounds.

766. WIGTONSHIRE. A surface three miles broad, varied and fertile, with few hills and no mountains.

Galloway House, — near Carlisle; Earl of Galloway. A large house surrounded by extensive plantations, enclosed by a stone wall. Here figs ripen against a common garden-wall.

Broughton House, — near Gatehouse; Murray, Esq. A good house, situated on an elevated surface, and backed by old woods and young plantations.

767. AYRSHIRE. A surface of 1600 square miles; partly hilly, and very generally under pasture. There are a number of private orchards in this county; some of them a century old, and very productive. There is a productive kitchen-garden: the whole in high keeping.

Kilmarnock Nursery. — Messrs. Sampson have an extensive and highly respectable establishment; and there is another equally respectable, but of more recent origin.

Market-Gardens, — there are several, from one to six acres in extent, near the principal towns, and containing about 2000 hardy exotics, besides a very full collection of British, and about 1000 acres of Ayr. Their main crops are onions and carrots, of which they export large quantities to Ireland. There are also market-gardens at Newmilns, Newcraighall, and Newcastleton. There are also two very good plantations.

Runcorn Castle, — near Culzean; Earl Castleis. A noble mansion, with a kitchen-garden attached, which has a bold precipice on the Carrick shore; the offices adjoining forming a fine town house. About 700 acres, richly wooded, and abounding in marine views; in the pleasure-gardens is an extensive collection, both of hardy and tender orchards, which, owing to the extension of the town, is now situated near its centre; it contains two Scotch oaks and some pear-trees of a large size and venerable aspect.

768. RENFREWSHIRE. A surface of 155,507 acres; abounding in hills, and moors, and with a cold moist climate in the elevated district. The most remarkable gardening feature in this county is the florist gardens of Paisley.

Market-Gardens and Orchards. — There are several market- gardens round the sea-ports of Greenock and Port Glasgow; and some orchards at the latter place. There is also a very old
GARDENS of the OPERATIVE MANUFACTURERS OF Paisley.—The operations of Paisley, taking them at large, exhibit a condition of things as follows:—In the year 1794, there were, as usual among persons in the same rank of life; and they are particularly remarkable in their taste for objects which please the eye by their harmony of form, for such furtherance of that elegance and nice attention, and for various intellectual gratifications. In their gardens, and for their furnishing their garden beds, and in a similar kind, they study a great degree of neatness. Even there is a certain selectness of species, in the names of which, are known in the vicinity to be distinguished for their beauty and variety. Several operations of that kind in the management of balls and flowers seem to communicate to each other their various expedients and success. It will perhaps be difficult to find elsewhere, in the same place where the competition is the same, that it is not to be equalled by the operations in any place. The only operative manufacture, as perhaps in any other, who can be compared with them for information, are the milliners at Leeds, who work but six hours a day, and have with success devoted much more attention to the purchase of material for the adornment of the mind. But the intellectual attainments of the Paisley operations must be more highly appreciated than the Leeds; and are probably in no department inferior.

The statement of the private reading societies in Great Britain, which was some years ago exhibited in the newspapers, it appeared that a very considerable proportion of the whole (it is believed less at that time than the third) existed in Paisley. How far any of these attachments and habits may have been supported by the influence of gardens, or may be easy to determine, but all of them in some measure preceded the epoch of science and instruction in Paisley.

It has been remarked by a gentleman of learning and philosophical observation in Paisley, the Rev. William Forrester, that this constant dissipation of temper is of a considerably degree an effect of the peculiar manufacturing habitudes of the country. Their constant usage, their constant execution of the most delicate ornamental muslins, but for the instruction of their minds, and for the better stand unrivalled. Their ingenuity is continually in exertion for new and pleasing elegancies, to diversify their fabrics. Now, with the same aim, and the same skill, with which is object an very congenial to them, will easily be adopted, and made to flourish in the garden, on the other hand, it seems highly probable, that the rearing of flowers, by a recreation, tend to improve the genius for invention in elegant fancy muslins.

The florists of Paisley (it is observed by the same gentleman) are inhabitants for the decoration of their houses, of their dispositions, and the sobriety of their manners. The Florists of Paisley are more learned than any others, in realities, which dismiss an at the evening; but would be from their variety of different flowers. It is pleasing to think, that not only the attachment of individuals to the culture of beautiful flowers, but the association of persons possessing this taste, lead to the cultivation of the physical.

Origins of the Floral Society.—The culture of plants became a regular concern in Paisley and its vicinity, between the years 1765 and 1790. Till then, none but those of the most distinguished breeders, were known there. But at that period, some seeds, reputed of good quality, were procured from London: the great bulk of these produced plain plants. In a few instances, however, four sorts appeared; which, being sent to Paisley, were highly admired. The seeds of these were carefully preserved and cultivated. The public request of such plants increased from them. The florists persevered in cultivating these; and, at the same time, did not neglect other kinds brought year after year from London, where they were greatly excelled in varieties. And, being in general as good, if not better, than any cultivated by the seeds of the finest plants, the original qualities were not only preserved, but improved. For some years past, all improvements, whether cultivations, or new varieties, have been sent by order to London, and have been pronounced equal in beauty and quality to any elsewhere commoner.

The spirit for improving plants, and many other kinds of flowers, is cherished in Paisley by an appropriate institution, viz.

7629. LANARKSHIRE. A surface of 556,800 acres, hilly and bleak, but with some fertile valleys. The chief industries and manufacture are coal and capital; Clydebank is noted for its orchards, and the total number of acres in the county occupied in this way is estimated at 340. There are some gardeners' lodges, florists' lodges, and meetings, and a horticultural society, held at Glasgow.

The surface of the area is happily considerably varied, which adds greatly to the effect of the irregular groups and compartments; and it is fortunate also in having agreeable exterior scenery (fig. 754), which, to the spectator walking in the gardens, forms a fine background to the hot-houses, and at the same time shelters them from the north winds.

Glasgow Nurseries—occupy about 60 acres; the principal are carried on by Austin and Co. and Brown.

The Market-Gardens of Glasgow—are estimated to occupy 260 or 270 acres, which are cropped chiefly with the commoner articles: sea-kale, artichokes, beets, endive, French beans, and shallots, are not in demand; and other rarer sorts are unknown. Thirty acres, however, are occupied in raising strawberries for the Glasgow market, and an acre in a good season is estimated to produce from 800 to 900 Scotch pints, or about four times that number of pottles.

Clydesdale Orchards—These are 60 in number, and occupy from 210 to 220 acres between Glasgow and Lanark. The largest contains about 30 acres. The fruits produced are apples, pears, plums, gooseberries, and currants. Many of them occupy steep banks, and are never cultivated. The others are chiefly ploughed, unless where the small fruits are grown in the intervals of the trees. The produce finds a ready sale in Glasgow and the sea-ports; and the demand seems increasing.

Hamilton Palace,—at Hamilton; Duke of Hamilton. A gloomy old fabric, situated on one side of an extensive park watered by the Clyde; well wooded with old oaks, and distinguished by an extensive frontage, or false palace, on an eminence, called Chasitbernuit ( Herald's Castle), said to be
in imitation of the duke's residence of that name in the cir-
cle of Vienne, in France. The azaleas grown in Hamilton
Park are reckoned the best produced in Scotland.

Book I. GARDENS OF SCOTLAND.

Gardens of Earl Hogg, one of the most
finely cultivated. There are however, and still
are, some extensive and noble golden pippin-trees
in Scotland, generally very productive.

7630. DUMBARTONSHIRE. A surface of 159,556
acres, chiefly mountainous, abounding in 
moses and moors, with some natural woods, in which
the holly and yew are more common than anywhere
else in Scotland.

Orchards. There are rare, though fruit-trees thrive well in
the county. Excellent apples are produced in the traders'
gardens of Linlithgow, and Linlithgow is an orchard
belonging to Macdonald Buchan of Ross, which contains
two of the largest and most productive
excellent pippin-trees in Scotland, generally
very productive.

7631. STIRLINGSHIRE. A surface of 450,560
acres of fields and fertile valleys; the latter generally
under aration. There is a nursery at Stirling, and some market-gardens of the commonest kind between
that town and St. Ninians, and at Falkirk.

Orchards. There are upwards of 80 of these in this county,
growing almost exclusively in pippin-trees, and all are
little grown in the county. The green-ripe pears ripen in
the garden, and are seen as a standard. The most
productive of pears, near Kircaldy, were planted
by Wilkins; the park extensive and finely wooded, and
subdivided in the manner peculiar to the
county, so as to be rendered available as a grazing-

Farmers' Houses. — near Queensferry: Earl of Hopetoun.
One of the most stately and imposing
gardens in Scotland, in (rectangular ground),
was formed by Sir W. Bruce, and finished by Adams. It stands on
the shores of the Forth, a mile in length, washed
by the sea, and is surrounded by extensive woods and
plantations, a pleasure and kitchen garden in high
cultivation.

7632. LINLITHGOWSHIRE. A surface of 71,580
acres, agreeably varied, generally under mixed
culture, and beautifully watered on one side by the Forth.
There are a few market-gardens about
Bo'ness, Daldowie, and Linlithgow.

Haddooge Park, — near Queensferry: Earl of Rosebery.
A castellated mansion on a rock with a basin of greater
beauty much imitated in the Achars
by Wilkins; the park extensive and finely wooded, and
subdivided in the manner peculiar to the
county, so as to be rendered available as a grazing-

Farmers' Houses. — near Queensferry: Earl of Hopetoun.
One of the most stately and imposing
gardens in Scotland, in (rectangular ground),
was formed by Sir W. Bruce, and finished by Adams. It stands on
the shores of the Forth, a mile in length, washed
by the sea, and is surrounded by extensive woods and
plantations, a pleasure and kitchen garden in high
cultivation.

7633. CLACKMANNANSHIRE. A surface of 30,730
acres, beautifully varied, with few-hills, and
generally well cultivated. There is a market-garden at Alloa, of about five acres, and some small
nurseries.

Orchards. There are some near Clurose: one called Castle-
hill is at least two centuries old. The apple-trees are
exhausted with age, but the pear-trees remain in full bearing;
the near Clurose. The best pears in the
principal farms in the county are the late sorts.

Shaw Park, — near Kincardine: Earl of Mansfield.

7634. KINROSS-SHIRE. A surface of 39,702
acres, considerably varied by hills, valleys, streams, and
a large lake.

1 Blair Adam, — near Kinross: W. Adam, Esq., Remarkable
for the extent of the plantations on a large
peat soil.

7635. FIFE SHIRE. A peninsula surface of 252,750
acres, finely varied by hills, valleys, a mountain,
some lakes, and bounded on one side by the Forth, the other by the Tay, and the third by the open sea.
It is an old county, well cultivated, and containing some fine country-seats of moderate extent. Though
the climate is unfavorable for the larger fruits, yet in no county of Scotland are gardens so general from the
coast to the mansion, or so well managed : as a proof, there is scarcely such a thing as a market-garden
in the county.

Kirkbylae Nursery, — at Kirkbylae; Sang, editor of The
Plender's Calendar, and an extensive contractor for planting
and plantations. Again there is also a
few-hills, and at some towns.

Market-Gardens. — There is one of six acres, surrounded by
a high fruit-wall at Kirkbylae; one of nearly equal extent at Fifehead, and one or two more at different parts
of the county.

Orchards. — There are some of recent formation, excepting one
at Burns Park, Sang in 1811; but the remains of fruit-trees
are still to be seen at the ancient abbey of Lindores.

Longwy Castle, — near Kirkbylae; Tson. Wendys.

7636. PERTHSHIRE. A surface of 4,068,640
acres, much varied by hills and mountains, but contain-
ing some fertile valleys called straths and crags. It contains some excellent country-residences. The
cream-colored cherry of Ardvorlich, and the black bean of Castle Menzies, are mentioned by Dr.
Robertson (Agr. Sur. of Perthshire) as being much esteemed. There is a respectable nursery at Perth,
one at Dunblane, and some lesser ones at Dunkeld, and other places; there is also a Horticultural Society
held at Perth.

Perth Nurseries. — contain between 50 and 60 acres; the
principal is at Dickson and Brown; in whose extensive
and highly systematical garden, one of the finest
varieties of the Scotch rose have been originated from
seed.

Market-Gardens. — Dundee is said to be better supplied with
vegetables grown in any other town in Scotland. The quantity
of ground on which they are grown is estimated at 100 acres;
and James Reid, in 1750, was the first who excelled in this mode
of culture. The shipping ensures a brisk demand for common
articles.

Orchards. — There are upwards of twenty in the Carn of
Gowrie, situated on the last northern shore of the Tay,
chiefly from Kincardine to the town of Dunkeld. The oldest are
about 100 years; the soil is a deep mud or clay. They occupy
in all manner of soils, and are also a flourishing industry
along the arched bases of the Ochil hills.

Some Pulpits, — near Perth: Earl of Mansfield. A noble
castle-like mansion, formerly the seat of the earls
of Argyll, and lately occupied by the earl of Argyll, whose
estates include the finest situation in Scotland, with a front in great extent, washed by the Tay, and backed by rising grounds covered with wood.
The gardens and pleasure-grounds extensive, complete, and well managed.

Drummond Castle.—near Perth; Earl of Kinnoull. A good house, and well planted ground. For over 450 yards in length, scarcely equalled any where.

Donwed House.—at Dunkeld; Duke of Atholl. A large plain house, and extensive terraces are surrounded by hills, and covered for their extensive plantations, especially of the larch, and for their romantic walks, waterfalls, streams, and ornamental walks.

Obira House.—near Crieff; Lord Moray. A large house, and extensive grounds, and extensively improved by the present owner. Recently planted by Lewis Kennedy.

Ochtertyre.—near Crieff; Sir P. Murray. A finely wooded place, trees and shrubs managed by the present owner; the kitchen-garden and hot-houses laid out by Nicol.

Colster House.—near Blairgowrie; Lord Duncan. An excellent kitchen-garden, by Hay of Edinburgh.

Yewfield.—near Callow; Sir H. Preston. A romantic residence, laid out from designs by Repton, whose son visited this place about 1794. The principal feature consists of a strange notice arranged on a wooden granary.

Campfill.—near Crieff; Mr. Graham Esq. A fine old place, noted for its ancient trees, especially of pines from Sweden, and a fine kitchen-garden by Nicol.

Grenville.—near Culloden; R. E. Abercrombie. A house in the mixed style of Gothic and Grecian, of Adams, standing in a finely varied grounds, well planted, and containing a fine kitchen-garden.

Castle Gray.—near Perth; Earl Grey. A good house, by Arkishoon, in a delightful and well wooded situation.

A surface of 2,935,520 acres, mountains with extensive and fertile valleys; the former generally bearing good pasture, and the latter under market gardens; and, Arbroath and Arbroath have a few small market-gardens; but many of the tradesmen cultivate spots of ground for their recreation; and besides supplying their own families, produce a sufficiency of culinary vegetables and small fruits to meet the demands of their townsmen. It is estimated that upwards of 53,000 acres are covered with plantations, and sometimes this county will be celebrated as having given birth to the Dons, a family of botanists of superior order.

There is also a small green-house, containing above 1000 different species, and some of them in flower; but the botanic garden is still kept up.

Castle Cameron.—near Stirling; Earl of Strathmore. A very ancient building, renovated by Inglis Jones; the grounds in the ancient style, and containing some fine old trees.

Kincardineshire. A surface of 243,444 acres, mountains towards the north, but more level and fertile on the south-east.

Brodie House.—at Brodie; Alexander Brodie, Esq. P. L. S. A fine old mansion much improved, and present

Aberdeen. A surface of 718,601 acres, generally flat, but varisted by knobs, wavy ridges, and gentle inequalities, formerly moory and bleak, but now extensively planted. It is said, that there is scarcely a gentleman in the county who has an estate of 100 l. a year who has not planted some hundred thousand trees, and that there is above 50,000 acres in the county covered with artificial plantations. There are a number of ruined mansions in Aberdeen noted for raising seedlings, many of which are sent to the south of Scotland and to England.

The Aberdeen Nursery.—Messrs. Reid. An old and respectable establishment chiefly devoted to the culture of forest trees, and especially to seedlings of Scotch pine, larch fur and thorns. The father of the present occupier, Mr. W. Grant, is also proprietor of the soil (twelve acres), was gardener to Sir Archibald Grant of Abergeldie, and was the greatest planter in Scotland.

Laing's Nursery.—a newly established concern, carried on with great spirit. There are various other nurseries.

These are not inconsiderable, both for the supply of the town, and shipping. Almost the entire parish of Old Newbury is occupied in the nursery business; in 4 acres of ground several hundred industrious men. At Padderness there are also gardens for growing vegetables for this purpose.

The nurseries contain the most magnificent trees and shrubs ever raised in Scotland, and are assisted by the latest improvements. In many cases the trees are in a neglected state between Rannoch and Moray; and the confidence of the proprietors on being transported to the south and east.

Gardens—near Invercauld; — Farquharson. Esq. Famous for its pine-forests, the timber of which equals that of any in the north of Scotland.

Stains Castle.—near Stains; Earl of Erroll. Situated on the margin of a fine sheet of water, near a magnificent cottage, and containing a good kitchen-garden.

Don House.—near Aberdeen; Professor Darson. A romantic villa, the gardens forming terraces cut out of granite rock, watered by a stream, where grow naturally many rare plants, especially among the Linnum boreale. The whole kept in the highest order and neatness.

Banchory. A surface of 649,600 acres, cultivated. There are some good market-gardens at:

Duff House.—near Duff; Earl of Fife. A magnificent quadrangular building, by Adams, in a park 10 miles in circumference, laid out by the late Lord Fife. On the other parts of the estate are more trees planted than on any part of the property.

Gordon Castle.—near Gordon; Duke of Gordon. A large house, the grounds celebrated for their fine woods, extensive plantations, and extensive kitchen-garden.

Cullen House.—near Cullen; Earl of Fyfe. Remarkable for its fine old woods; the late earl being one of the earliest and most extensive planters in the country.

Bonvilston, Ross, or Sutherland. A surface of 393,680 acres; generally flat; described by Pennant as an immense morass, with some fertile spots. From the materials which compose this morass, it appears to have been formerly full of wood; but recent attempts to raise plantations have not been very successful. There is a remarkable tarn at Thurso, covering 7 acres; a remarkable circumstance, as there are not a few in the counties of Cromarty, Ross, or Sutherland.

Thurso Castle.—Thurso; Sir J. Sinclair. Chiefly remarkable for agricultural improvements, but displaying also some plantations, and a kitchen-garden, and many ingenious but abortive attempts at amelioration.

Orkney and Shetland Islands contain nothing that we have heard of worthy of notice in the way of gardening. Such a thing as an orchard is unknown in these islands. In Orkney, Neil observes (Gen. Rep. sect. l. p. 180), a few apples are produced on wall-trees; in Shetland still fewer, and that only in particularly good seasons.

Sutherland. A mountainous uncultivated surface of 1,475,400 acres; about half of which is the property of the Marquis of Stafford, who has enlarged the farms, built new farmhouses, and
Gardens of Ireland

764. MOURNE.HILLS.—There are few public or commercial orchards, but some private ones, of which a great part is produced in the county, and the remainder is sent to the markets of other counties. There are a number of good apple-trees, and some fine pears, but no other fruits are grown in any considerable quantity.

In the Mourne Mountains, there are a number of good apple-trees, and some fine pears, but no other fruits are grown in any considerable quantity.

765. BUTE.—This county is well watered, and contains a great variety of trees and shrubs. The soil is generally well composed, and the climate is mild and temperate. The gardens are well stocked with vegetables, and the people are fond of gardening. The soil is generally well composed, and the climate is mild and temperate. The gardens are well stocked with vegetables, and the people are fond of gardening.

766. ARGYLL.—An extensive surface of land is cultivated in the counties of Argyll and Inverness, and the gardens are well stocked with vegetables, and the people are fond of gardening.

800 square miles, consisting of hills and mountains, with several islands considered as belonging to it. It abounds in lakes and streams, and contains a great variety of trees and shrubs. The soil is generally well composed, and the climate is mild and temperate. The gardens are well stocked with vegetables, and the people are fond of gardening.

767. BUTE.—This county is well watered, and contains a great variety of trees and shrubs. The soil is generally well composed, and the climate is mild and temperate. The gardens are well stocked with vegetables, and the people are fond of gardening.

768. INVERNESS.—This county is well watered, and contains a great variety of trees and shrubs. The soil is generally well composed, and the climate is mild and temperate. The gardens are well stocked with vegetables, and the people are fond of gardening.

769. ABERDEEN.—An extensive surface of land is cultivated in the counties of Aberdeen and Banff, and the gardens are well stocked with vegetables, and the people are fond of gardening.

800 square miles, consisting of hills and mountains, with several islands considered as belonging to it. It abounds in lakes and streams, and contains a great variety of trees and shrubs. The soil is generally well composed, and the climate is mild and temperate. The gardens are well stocked with vegetables, and the people are fond of gardening.

770. CLACKMANNAN.—This county is well watered, and contains a great variety of trees and shrubs. The soil is generally well composed, and the climate is mild and temperate. The gardens are well stocked with vegetables, and the people are fond of gardening.

771. ORKNEY.—This county is well watered, and contains a great variety of trees and shrubs. The soil is generally well composed, and the climate is mild and temperate. The gardens are well stocked with vegetables, and the people are fond of gardening.

772. THE STRANGERS' GARDEN.—This garden is well worth a visit, and contains a great variety of trees and shrubs. The soil is generally well composed, and the climate is mild and temperate. The gardens are well stocked with vegetables, and the people are fond of gardening.
and favorable for all the other branches of gardening. The political situation of the country, and the general absence of proprietors, have prevented much from being done; but, from the cheapness of land and labor, and the natural advantages everywhere present, the most extensive parks, pleasure-grounds, and kitchen-gardens, might be created at a comparatively moderate expense.

7652. The names of residences here given are selected from the Traveller's Guide, published in Dublin in 1819: the characteristic epithets added are from that work, and the English reader will of course make due allowance for Irish phraseology. We have made the general tour of Ireland, and been engaged professionally in three or four counties, and we know that many places, styled delightful and enchanting in the "Guide," would cut but a poor figure if placed beside hundreds of seats in England whose names we have omitted. There is very little old timber in Ireland, and very few of the "demesnes" that have any other park than a grass field, without trees, in which the house stands. Deer parks are rare, and also kitchen-gardens with hot-houses. Mackay of the Trinity College botanic garden, and Mr. Leish of Harold's Cross, are well calculated for furnishing designs for both these improvements, and happily there is at present a spirit for employing these gentlemen. If to this the proprietors would join not a constant residence on their estates, much would be effected.

PROVINCE OF LEINSTER.

7633. DUBLIN. A fertile surface of 147,840 Irish acres, little Varied, but well adapted for horticulture and floriculture. At Dublin is a royal park; two excellent botanic gardens; two good nurseries by Simpson, Toole, and Mackay, and Grimwoods and Keefe, with some culinary commercial gardens (Illust. St. Ser.) and a green, a very large naked square, a design for ornamenting which by A. Leish is about to be published.

The Phoenix Park.—near Dublin; a public promenade and a royal park, seven miles in circumference, beautifully diversified with woodland, campagne and rising grounds, tastefully adapted and executed, and almost uniformly stocked with deer. The civic royal residence here is respectable and commodious. It is reckoned one of the best managed in the county of Dublin.

The Botanic Garden,—at Glasnevin (fg. 757); Dublin So.

To avoid this appearance, each class is subdivided into smaller compartments, insulated in green award, and commencing by pathways, and the intervals filled up with seats, and sometimes a circular promenade also. Regularity is observed in the classification, and the series of plants follow each other in such succession that the visiting promenade is immediately furnished with a pleasing scene without presenting the aspect of unattractive confusion.

This garden contains the following arrangements, or subdivisions:

A Hortus Linnaceus (a), subdivided into a herbaceous division, and for shrubry, fruit-bearing, and forest trees.

Six acres are assigned to this division. To each plant is prefixed a metrical description, inscribed with its number in the Glasnevin catalogue.

A Hortus Javanensis (b), rather limited, yet sufficiently extensive to comprise all the orders of which there are hardy specimens introduced in Britain.

A Hortus Cornutus (c), or garden of native Irish plants, containing upwards of 1356 species, including Cryptogamen.

A Hortus secundus (d), containing not only the, as culinary vegetables, but all others in which wholesome and nutritious qualities reside, in such a degree that they can be converted into human aliment.

A Hortus medicus (e), or garden of plants used in medicine, arranged on the plan of Wollaston's Medicus (Dublin, 1727).

A Hortus floribundus, containing every hardy plant in which any medical virtue is known to exist.

A Hortus pecuniarus (f), or cattle garden, in which are arranged all plants which the animal to whom the plant is appropriated is enabled to enjoy, and which are wholesome food for it; also such as he is not fond of eating, though not unwholesome. The opposite order are arranged on the same plan; as in the same animal will eat, but which are injurious to it, and likewise such as it refuses to eat whether wholesome or injurious to it.

Each of these particulars is noted on the label, pointing out the plant, and likewise whether the plant be indigenous or foreign.

A Hortus rusticus (g), containing different species of plants used in rural economy, including the grasses, clover, &c.

Hortus domesticus (h), containing all the plants used in dyeing, particularly those which are indigenous to Ireland.

A Hortus plantarum usitatum, reptantium, accrescentium, (i), or garden of twining, creeping, and climbing plants, shrubry and herbaceous.

A Hortus planatum saxicolaum, or garden of rock plants on rock-work. This is formed on an artificial mound, constructed on the most elevated part of the garden. The fragments of the iroccrowed ruin of some venerable arch presents a passage, so that many of the compartments are approached by some picturesque or striking entrance. Nor is the garden’s arrangement less judiciously managed. Nothing can be conceived more ungraceful than the formal regularity necessary in such an arrangement; every plant following to its order, and labelled with its name, presents to the eye an intricate sameness.
GARDENS OF IRELAND.

A Hortus exoticus (p), or garden for tender exotics, comprising a conservatory, two green-houses, and a hot-house placed together upon the present ground, and commencing by a common passageway on the north end.

A Professor's house and Lecture-room (q), with a library-hardware, etc. The beauty of the former property isticket, is preserved, and arranged for this purpose.

This garden is managed by a professor and lecturer, with a salary of 500l., a superintendent at 100l., two assistants at 60l. a year to gardeners at 1l. per week, and six apprentices at 6s. The total annual expense, including 700l. as rent for the land, is about 1500l. a-year. Besides the usual number of gardeners, six who have the usual experience are employed in another extensive garden, and have received the professor's instructions. After passing two years they here are received as gardeners in the garden, on the same terms as the others mentioned above. A premium of five guineas is given by the society to those who are recommended by the superintendent for assiduity and good conduct.

Newcomen, near Donnybrook; — a magnificent mansion, together, with agreeable pleasure-gardens.

Tolka Palace, — near Tallagh; Archbishop of Dublin. An ancient venerable structure, with extensive gardens, kept in fine order.

Of Villa Gardens. — There are a very considerable number that might be enumerated, such as St. Catherine's, belonging to the bankers Lasor; St. Wwelmans, — Kano, — Mount, — and several near Bray, Lucan, Lestiff, Countess, &c. — near Donnybrook; — Stupendous rocky scenery, with old trees in the park.

Mount Kilkenny, — Earl of Charlemont. A delightful edifice, in a demesne of 900 acres, judiciously and tastefully planted, with a fine ornamental temple. The gardens and grounds are thrown open two days a-week.

Merrville (sea villa), — near Donnybrook; — Lord Dowes. A beautiful edifice, close to the sea, surrounded by extensive fields of ornamental plants; a greenhouse, a cover, flower forcing-house, by, and a magnificent mansion, with beautiful lawns, and a large lake.

Leopards Town, — Lord Castlecomer, situate at the bottom of the town, and having in picturesque views from the house and walks in the pleasure-ground.

Treevern, — F. Bourne. — Extensive hot-houses and gardens, consisting of extensive plantations, ranged in a systematic order, and managed by Mr. Fraser, an excellent botanist and gardener, and a man of extensive knowledge. — Mount Merrion, — near Donnybrook; — Lord Fitz Williams. A magnificent mansion, with gardens and parks.

Newcomen Park, — near Donnybrook; — a magnificent mansion, and some trees in the park.

Killererin — near Rathfranham Castle; — a magnificent castellated structure, with agreeable pleasure-ground.

Belview Palace, — near Tullagh; — Bishop of Dublin. A splendid residence, with extensive gardens, well managed, and kept in fine order.

Lord Rossmore. Extensive plantations, and a waterfall of 100 feet, also near the Devil's Fillip, — Powerscourt, — near Emlicky; — Lord Powecourt. An extensive demesne, of 500 acres, tastefully planted, and ornamented with water and buildings.

Charles L. Encashe, — Lord Mount Tomlinson, situated on the river Dargle, with a luxuriance of rural beauties.

Blessington Park, — near Blessington; — Marquis of Downshire, — near Knockmore. — The house consumed in the rebellion of 1798, and not yet refitted. This place was formerly famous for the first kitchen-gardens in Ireland.

Rathmore, — near Kna; — Earl Miltown. The front of the house, in form of an extensive facade of born stone, over 700 feet long. The grounds finely varied and well planted.

Lord Newcomen, — near Castle Carberry; — Lord Harferton. A beautiful seat.

Kildare. — near Bennett's-lodge; — Lord Desart. A magnificent mansion and extensive demesne.

Ardbrick, — near Durrow; — Lord Aschbrooke. A magnificent mansion, and extensive demesne.

Dunboy, — near Cross, — a fine and drawbridge, in a splendid flat demesne.

Frankford, — near Frankford; — an antique mansion, with a fine and drawbridge, in a splendid flat demesne.

Dunboy Castle, — near Dunshiffinin; — Lord Dunsmuir. Arden House, — near Trim; — Bishop of Meath. A chase and simple building.

Homestead, — near Kilbride; — Marquis Beechett. A magnificent mansion, and extensive and beautifully planted demesne.

Of boggy, hills, a number of lakes, and some fertile ground.

Westmeath. — A garden of 249,943 acres, of fine arable soil.

of Tookboy, — near Ballybof; — Lord Ormonde charming demesne; the mansion burned down during the rebellion of 1798, but restored by her ladyship.

Blenheim, — near Bray; — D. Loutache, Esq. A remarkable demesne, containing several lakes, and bogs, on which no expense is spared to preserve their reputation of being the first in Ireland.

Glenmore Castle, — F. Synge, Esq. Extensive mountain plantations going forward, varied scenery in the house, and gardens, with the finest collection of mountain and exotic flowers.

Kilbroney, — Rev. Dr. Trewel. Extensive kitchen-gardens, and the first cast-iron hot-houses erected in Ireland, from designs by Mr. A. M'Leish, M.R.I.A. Mentioned here in the open air to the height of sixteen or eighteen feet.

Kilbroney, — near Bray; — Earl of Metha. A romantic country seat, situated in a deep valley, overlooking two lofty mountains.

Newcomen, near Mount Kemmy, — near the village of that name; — a splendid seat.

Wicklow.

A peninsular surface of 315,396 Irish acres, of good soil, but little varied in aspect.

Camolin Park, — near Eniscorich; — Earl Mountmorris. A beautiful demesne.

Kilkenny.

A surface, somewhat varied by hills, of 318,349 Irish acres. There is a good nursery here, by John Robertson, who has distinguished himself by some excellent papers published in the Transactions of the London Horticultural Society.

Doran, — near Bennet's-lodge; — Lord Desart. A magnificent mansion and extensive demesne.

Ashmore, — near Durrow; — Lord Aschbrooke. A magnificent mansion, and extensive demesne.

Carlow.

A garden of 137,000 acres, of grand and picturesque surface and good soil.

Eastermeath. — A fertile surface of 227,500 acres, generally flat, but with only a moderate portion of bog and waste.

Gorteenstown House, — near White Cross; — Lord Gorteenstown.

Stane Castle, — near Stane; — Earl Conygham. A splendid mansion, surrounded by a large and extensive garden, which flows the Bows, planting and being otherwise improved.

Westmeath.

A garden of 249,943 acres, of fine arable soil.

of villa Gardens. — There are a very considerable number that might be enumerated, such as St. Catherine's, belonging to the bankers Lasor; St. Wwelmans, — Kano, — Mount, — and several near Bray, Lucan, Lestiff, Countess, &c. — near Donnybrook; — Stupendous rocky scenery, with old trees in the park.

Mount Kilkenny, — Earl of Charlemont. A delightful edifice, in a demesne of 900 acres, judiciously and tastefully planted, with a fine ornamental temple. The gardens and grounds are thrown open two days a-week.

Merrville (sea villa), — near Donnybrook; — Lord Dowes. A beautiful edifice, close to the sea, surrounded by extensive fields of ornamental plants; a greenhouse, a cover, flower forcing-house, by, and a magnificent mansion, with beautiful lawns, and a large lake.

Leopards Town, — Lord Castlecomer, situate at the bottom of the town, and having in picturesque views from the house and walks in the pleasure-ground.

Treevern, — F. Bourne. — Extensive hot-houses and gardens, consisting of extensive plantations, ranged in a systematic order, and managed by Mr. Fraser, an excellent botanist and gardener, and a man of extensive knowledge. — Mount Merrion, — near Donnybrook; — Lord Fitz Williams. A magnificent mansion, with gardens and parks.

Newcomen Park, — near Donnybrook; — a magnificent mansion, and some trees in the park.

Killererin — near Rathfranham Castle; — a magnificent castellated structure, with agreeable pleasure-ground.

Belview Palace, — near Tullagh; — Archbishop of Dublin. A splendid residence, with extensive gardens, well managed, and kept in fine order.

Lord Rossmore. Extensive plantations, and a waterfall of 100 feet, also near the Devil's Fillip, — Powerscourt, — near Emlicky; — Lord Powecourt. An extensive demesne, of 500 acres, tastefully planted, and ornamented with water and buildings.

Charles L. Encashe, — Lord Mount Tomlinson, situated on the river Dargle, with a luxuriance of rural beauties.

Blessington Park, — near Blessington; — Marquis of Downshire, — near Knockmore. — The house consumed in the rebellion of 1798, and not yet refitted. This place was formerly famous for the first kitchen-gardens in Ireland.

Rathmore, — near Kna; — Earl Miltown. The front of the house, in form of an extensive facade of born stone, over 700 feet long. The grounds finely varied and well planted.

Lord Newcomen, — near Castle Carberry; — Lord Harferton. A beautiful seat.

Kildare. — near Bennett's-lodge; — Lord Desart. A magnificent mansion and extensive demesne.

Ardbrick, — near Durrow; — Lord Aschbrooke. A magnificent mansion, and extensive demesne.

Doran, — near Cross, — a fine and drawbridge, in a splendid flat demesne.

Frankford, — near Frankford; — an antique mansion, with a fine and drawbridge, in a splendid flat demesne.

Dunboy Castle, — near Dunshiffinin; — Lord Dunsmuir. Arden House, — near Trim; — Bishop of Meath. A chase and simple building.

Homestead, — near Kilbride; — Marquis Beechett. A magnificent mansion, and extensive and beautifully planted demesne.

Of boggy, hills, a number of lakes, and some fertile ground.
timber, and the finest larches in Ireland. The house, gardens, and grounds had been much neglected, but are renovating and improving under the guidance of Mr. Leech.

Clonbrock, near Kingstown; Esq. A fine mansion and beautiful demesne.

Traffic every, near Marlow; Lord Riveult. A beautiful mansion and demesne.

Ballyfinnian, near Mullingar; H. O'Heffely, Esq. A charming residence.

Castletown-Deep, near Mullingar; Earl of Westmeath. A charming residence.

Parkhall Hall, near Castle Pollard; Earl Longford. A splendid seat.

Lismore Castle; — Captain Purdham. A house, offices, and castle, in the parish of Lismore, by Mr. Lord Lismore's extensive prospects, some old trees, and numerous young ones.

Knock Oir; — Sir R. Levinge, Bart. A large castle, by Sir R. Levinge, Esq., upwards of 60 acres of level and rocky

7653. LONGFORD. A surface of 134,700 acres of rich and beautiful spots, interspersed with bogs, mountains, and fens.

Castle Forbes, — near Newtoun Forbes; Earl Granard. A splendid residence.

7654. LOWTH. A surface of 125,000 Irish acres, fertile, undulating, and thickly interspersed with lofty hills.

Barmestown, — near Clougherhead; Sir E. Pellew. A charming mansion, encircled with an extensive and well-planted demesne.

7655. WATERFORD. A surface of 262,550 Irish acres varying through all the gradations of loam and peat.

Ballyhale, — near Tivartum; — A well planted demesne.

Carrignahone, — near Waterford; Marquis of Waterford. An extensive demesne, which for beauty and variety cannot be surpassed in any part of the united kingdom. Considered one of the best landlords in Ireland.

7656. CORK. The largest county in Ireland, comprising a surface of 1,048,700 Irish acres, of which 231,599 are bogs, mountains, and waste. There is a nursery by Thomas Sheeian.

Cork Botanic Garden — was founded in 1809, by the Royal Cork Institution (a society of gentlemen incorporated after the manner of the Dublin Society, and like that society supported by grants from the Earl of Lismore); six acres are enclosed by a hedge, and one acre near the centre by a wall; includes a hot-house and green-house. The plants in the garden are arranged in the Linnaean manner; it is managed by a committee, and the curator is Mr. James Drummond, A. L. S., of Lismore, and a practical gardener.

7657. TIPPERARY. A surface of 552,950 Irish acres, but level and fertile in the cast, where the lands are

Kilmore, — near Clonmel; — Bagnal, Esq. A beautiful seat.

Shanhill, — near Clonmel; Sir T. Osborne. A neat mansion.

Knocklowley, — near Clonmel; Lord Donoughmoe. An enchanting residence on the banks of the Barrow, finely planted.

Shanabally, — near Clonmel; Lord Lismore. A splendid residence.

Kilrowly, — near Ballyporeen; Sir W. Barker. A delightful residence.

Cathedral Place, — near Cashel; Bishop of Cashel. The gardens beautiful and tastefully arranged.

7658. LIMERICK. A surface of 366,750 Irish acres, generally flat and very rich, especially the tract of low lands on the Shannon, which are deemed the richest and most prolific in Ireland. There is a nursery in the county town, by Thomas Lees.

Ballymote, — near Askeaton; — Massey, Esq. A beautiful seat.

7659. CLARE. A surface of 476,250 Irish acres, of which more than half is bog, mountains, and waste; the mountains numerous, and the soil and surface of the lower grounds very various.

Finianblay, — in the village; the castle of the elder branch of the O'Brien family.

7670. KERRY. A surface of 647,650 Irish acres, much varied in surface and soil, and to a tourist the most interesting county in Ireland, containing the lakes of Killarney.

Mount Muckross, — near Castle Island; O'Donough, Esq. A charming residence.

Kenmare Lodge, — near Kenmare; Marquis of Landsdown. Kenmare House, — near Killarney; Lord Kenmare. A delightful view along the banks of the river Drinisc, at the mouth of which the aquatic exuas of the lake commenced. Round the lakes of Killarney is Belview, and various other houses of little or no interest, other than that from their situation. The banks and islands of the lakes are rich in botany, and display truly interesting copies and single specimens of arbutus unedo, as well as grand and picturesque views.

7671. ROSCOMMON. A surface of 346,650 Irish acres, with some lofty hills, but no lakes of any magnitude: it is generally in pasture.

Clonbrock, — at Stoketown; R. Mahon, Esq. A magnificent mansion.

7672. GALWAY. A surface of 869,950 Irish acres; varied and rich, but without hills or mountains:

Glanmore, — near Portumna; Marquis of Clandrackard. A venerable mansion.

Moycullen, — near Portumna; Lord Riverston. A delightful residence.

Shane's Garden, — near Kircourt; — Pierce, Esq. A pleasant residence.

Ballinareen, — near Woodruff; Right Hon. D. B. Daly. A fine and well planted demesne.

Kenmore, — near Kircourt; Earl Louth. A fine seat.

Cashel, — near Corr; B. Lyth, Esq. A splendid residence.

Garbally, — near Ballinacluie; Lord Clancarty. A splendid residence.

Ballyscullion, — near Aghrim; — A beautiful demesne.

Olahore Castle, — near Oranmore; — Blake, Esq. A venerable mansion.

Defensee, near Kilconlon; J. Daly, Esq. A splendid and magnificent mansion.

Clonbrock, — near Athoora; Lord Cholmly. A beautiful mansion, and highly improved demesne.

Believer, — near Newtown Believer; S. E. Believer. A beautiful seat.
I. LITERATURE OF GARDENING.

1097

7674. LEITRIM. A surface of 255,950 Irish acres; hilly, with fertile valleys, and numerous streams and lakes; the whole well adapted for every branch of gardening. Lurgan,—near Lurgan Bay; Right Hon. S. Winne. A beautiful residence.

7675. SLIGO. A surface of 247,150 acres, nearly the third quite waste, the rest fertile in corn and potatoes. Busheadown,—near Sligo, on Lough Gill; — The house and demesne aptly composed in elegant magnificence.

PROVINCE OF ULSTER.

7676. CAVAN. A surface of 301,000 Irish acres, abounding in fenny pastures and coarse grounds. Ranelagh House,—near Swadlinden; Earl Enniskillen. A splendid residence. Farnham House,—near Kilmore; Lord Farnham. A splendid residence, in an extensive demesne, abounding in lakes, bogs, copses, and meadows; an extensive demesne-farm, under the care of a Northumbrian agriculturist. All the upper tenants English.

7677. FERMANAGH. A surface of 283,400 Irish acres, chiefly boggy and mountainous; interesting to tourists as containing Loch Erne. Bellisle,—on an island in Loch Erne; Earl Rosse. The island contains 500 acres, charmingly diversified by hills, dales, and frosty declivities, which are clothed with old timber, through which gravel-walks are conducted, and a temple erected, from which a panoramic view is obtained, not only of this, but of all the other wooded islands of the loch. One of them is exclusively used as a deer park.

7678. MONAGHAN. A surface of 179,600 Irish acres, much encumbered with bogs and mountains, but in part rich and cultivated. Castle Blaney,—near the village of that name; Lord Blaney. A delightful residence, commanding a fine view.

7679. TYRONE. A surface of 467,700 Irish acres, a great portion rough and mountainous. Baron Court,—near Newton Stewart; Marquis of Abercorn. A magnificent mansion, but no park-scenery or gardens deserving notice. Expanse of plantations, however, have been made in various parts of the demesne. Caledon Hill,—near Caledon; Lord Caledon. A delightful residence.

7680. DONEGAL. A surface of 679,550 Irish acres; the greatest portion reclaimable and irreclaimable mountains.

7681. DERBY. A surface of 318,500 acres; its surface varied but without mountains, and the soil generally fertile.

7682. ARMAGH. A surface of 181,450 acres, with an irregular surface that has not unaptly been compared to eggs placed on end in a basin of salt.

7683. DOWN. A surface of 348,300 Irish acres, mostly.

7684. ANTRIM. A surface of 420,959 Irish acres, considerably varied with mountains and hills, fertile valleys, bogs, and dry wastes. It is noted by tourists as containing the Giant's Causeway. There are two nurseries at Belfast.

Chap. IV.

Of the Literature of Gardening.

7685. The first books on agriculture and gardening were written by the Greeks some centuries before the Christian era, and by the Romans about the commencement of that period. Among the ancient Greek writers, Hesiod, Homer, Theophrastus, Xenophon, and Theophrastus, may be mentioned as having touched more or less on gardening. The works of the modern Greeks, or those who wrote after the seat of the Roman government was transferred to Constantinople, are collected under the title of Geoponica; and have been translated by T. Owen, who also translated Varro and Palladius. Among the Latins, the works of Varro are the first in the order of time; next Cato, and Pliny, and Columella, and, lastly, R. T. E. Palladius, supposed to have lived in the fourth century. Passages relative to the subject may be found in most of the Roman poets, especially in Martial, Virgil, and Horace; but Pliny's natural history, and Columella's 11th book on gardens, are those from which the most correct ideas may be obtained of Roman gardens. In the ages which succeeded the fall of the Roman empire, few books were written, excepting on religion; the first which appeared on rural matters was by...
Crescenzo, in Italy, early in the fifteenth century; and soon after one or two in France, Germany, and Britain. We shall enumerate the whole of the British works on gardening, as far as we have been able to collect their titles; and next, the leading works of France, Germany, Italy, Spain, Sweden, Russia, and America.

Sect. I. Of the Literature of British Gardening.

7686. The first British work on husbandry is that of Judge Fitzherbert, published about the middle of the 16th century. Before the end of the same century appeared Tusser, Mountain, Mascal, and Hyll, who wrote expressly on gardening, partly from their own experience and observation, and partly by translating from the Latin and Greek authors. In the seventeenth century appeared as gardening authors, Plat, Lawson, Gardiner, Standish, Parkinson, Plattes, Austin, Tradescant, Evelyn, Cowley, Blake, Rea, Worldidge, Meager, Temple, and some others. Those of the succeeding century are numerous, and consist in great part of practical or professional gardeners, who wrote from their own experience; of these are London and Wise, Collins, Switzer, Fairchild, Miller, Cowell, Hitt, Hill, Wheeler, Boucher, Swinden, Abercrombie, Speechly, Forsyth, Maddock, M-Phail, Repton, and Nicol.

7687. Of amateur gardeners and botanists, who wrote on gardening during the eighteenth century, there are Laurence, Bradley, Evelyn, Justice, Hanbury, Weston, Wheatley, Chambers, G. Mason, Mason the poet, Anderson, R. P. Knight, T. A. Knight, U. Price, M. Marshall, and C. Marshall. The nineteenth century has produced one or two practical authors, as Pontey, Hayward, Emmerton, and Hogg; one gentleman writer on the subject, Hope; besides a number of authors of both classes, who have contributed papers to the Horticultural Societies.

7688. The old gardening books previous to the Restoration, Professor Martyn observes (Pref. to Mill. Dict. xxxv.), "are of very inferior value, with scarcely any pretence to originality, if we except Scot, Lawson, Parkinson, and Austen. Evelyn made a new era in planting and gardening. His first work was from the French, and published before the Restoration; but his great work, The Silva, was original, delivered before the Royal Society in 1662, and first printed in 1664. The same year his Gardener's Almanac was also published, and maintained its ground until Miller's Kalendar appeared. Cook assisted him in the article of planting; Sharrocks and Rea in that of gardening, which Cowley and Rapin ornamented with the flowers of poetry. Quintinie, with his followers, London and Wise, figured in gardening at the end of the same century: Liger, Laurence, and Bradley, at the beginning of the next; these were followed by Switzer and Fairchild, who lead us to the time of Miller, in 1724. Contemporaries with Miller were Batty Langley and Cowell. Miller, during his long career, had no considerable competitor, until he approached the end of it, when several writers took the advantage of his unwearied labors of near half a century, and fixed themselves upon him, as various marine insects do upon a decaying shellfish. I except Hitt and Justice, who are both originals; as is also Hill, after his fashion; but his gardening is not much founded in experience."

7689. The first considerable treatise on ornamental gardening is "Wheatley's, entitled Observations on Modern Gardening, and published without his name. Shenstone published his Unconnected Thoughts in 1764. There is an anonymous pamphlet on the Rise and Progress of the present Taste of Planting Parks and Gardens, in 1767; and an Essay on Design in Gardening in 1768, by George Mason. The English Garden, a poem by Mason, appeared in 1772. Knight published The Landscape, a didactic poem, in 1794. Repton, the same year, Sketches and Hints on Landscape Gardening, Marshall, a Review of the Landscape; and in 1796 he treated on ornamental gardening, in the second edition of his work on planting. Essays on the Picturesque, by Uvedale Price, Esq. in 1798. In 1803, a second magnificent work by Repton, entitled Observations on the Theory and Practice of Landscape Gardening, appeared; and another, Fragments on Landscape Gardening and Architecture, in 1716. Loudon's Observations on Planting and Landscape Gardening appeared in 1804; and his Treatise on Country Residences in 1806."

7690. The most useful works on gardening at the present time are, in horticulture, those of Forsyth, Nicol, and Abercrombie; in floriculture, that of Maddock; in arbiculture, those of Pontey and Sang; and in landscape-gardening, those of Wheatley and Repton. In the transactions of the horticultural societies are some valuable and original communications on the first branches, and especially on horticulture. In enumerating the principal British works on gardening, including some few of those on husbandry and botany, naturally connected with our subject, we shall adopt the order of the appearance of their authors, as writers on gardening; and when we can, we shall give short biographical notices. Those authors who have merely written articles published in the transactions of societies, or in public journals or magazines, are not here included, unless they have also written separate works.

The Customs of London, from the time of Richard I., &c. translated into English, and published at Antwerp in 1505, fol.; reprinted along with a series of English chronicles, in the year 1811, is divided into chapters, and contains the following articles:—

The act for trees above 30 years growing to pay no tythe. Trees in ye greenwood, and plantations and gardens, as well as colours in a taste. A treatise of the four ele- ments, and their several seasons, &c. The manner of planting and ordering the same. The fruits and meat to be eaten by. Percey (probably wrote) grew in an hour space, &c.

1509. The Bauple, Henry, the first printer in Southwark; the book to which he alludes was "the Grete Herbe, 1516;" and the first or second production which issued from his press.

The Assertion, Thomas, a yeoman, born near Witham, in Essex, 1515, received a liberal education at Eton school, and at Trinity-hall, Cambridge; lived many years as a farmer in Suffolk, and afterwards removed to London, where he published his first work in 1557, and died in 1580.

1. The Honest Farmer of Good Husbandry, as well for the Middle Land and Open Country as for the Woodland. Lond. 1557. 4to.

1571. Mountain, Didymus.

1. The Gardener's Labyrinth; containing a Discourse of the several Elements, and how they were disposed on his plot of land, for the use of a Garden; with Instructions for the choice of Needes, apt times for Sowing, Setting, and raising the several Kinds of Plants, as also, for ordering the same serving to that use and purpose; whereinto are set forth, divers Rules and Observations, for the best Ordering of a Garden, as the beautifying of Gardens, and also the Physicke of each Herbe, &c. Gathered out of the best approved Writers of Gardening, Husbandry, and Physicke, &c. Lond. 1571. 4to.

2. The Second Part of the Gardener's Lineament; vizt. such as contain the most pleasant experiences and worthy Secrets, about the particular sowing and remov- ing of the most kitchen Herbes; with Rules and Observations concerning the best and orderliest manner of planting the Flowers, pleasant Fruites, and fine Rootes, as the like hath beene procured by his virtuous Figures and skilfull di- rections of each Herbe annexed, with the commoditie of Waters distilled out of them, right necessary to be known. Lond. 1577. 4to.

1574. Hill, Hylt, or Hyte, Thomas, a London au- thor of various works on Dreams, Physiognomy, Mysteries, in Almanack, Astronomy, Arithmetic, &c.; died in the beginning of the seventeenth century.

The Profitable Arte of Gardening: to which is added much necessary matter, and a number of secrets, with the Physicke of all Herbes belonging to each other art. London. 4to. To this is annexed two proper Treatises, the one entitled the Marrashians Government, Propertie, and Bene- fitts of the Garden; with the rare Secrets of the Honne and Waxe. And the other, the Yerely Conjectures mete for Husbandmen. To which is annexed the best way of cutting and ordering of Plants. Gathered by Thomas Hylt, cit- izen of London. Lond. 1574. 4to.

1599. Platt, Sir Hugh, author of various philo- sophical works, and apparently a lawyer. "Sir Hugh Platt (says Weston) spent part of his time at Copt-hall in Essex, and at Bishop's-hall in Mid- dlesex, at each of which places he had a country seat; but his town-residence was Lincoln's Inn." In the Jewell House of Abraham, North, Platte, or Platt, which was spelt both ways, of Lincolnes Inne, gentleman. By the same book it appears that he then (1594) lived at Bishop's-hall, and had an house in St. Alphage, Westminster.

He does not inform us what profession he was of, only that it was alien from the studies of husbandry and gardening. He may have had a very numerous family, for six of his children died of the worms.

It appears from his Garden of Eden (p. 93), that he was living in the year 1600; and that he had a garden of 200 acres. Martyn's Land, in Middlesex,

1. The Jewel House of Art and Nature, containing divers rare and profitable Observations and Directions: En- periering all Points of the Art of Husbandry, Distracting, and Mourn- ing. Faithfully and Familiarly set downe, according to the Author's Knowledge, of the Travell of Sir Hugh Platt, or Platt, (for it is spelt both ways), of Lincolnes Inne, gentleman. Lond. 1591. 4to.

2. Two Gardens of Eden, containing an accurate Description of All Flowers and Fruites now growing in England, with particu- lar rules how to advance the same, and encreasing all well in earth, as the secret ordering of Trees and Plants. By that learned and great observer, Sir Hugh Platt, knight. The fifth edition. Lond. 1666. small 8vo.

The statistics of gardening.

Part IV.

1637. *Platen*, Gabriel, a poor man, but a useful writer. Harri says, he had a bold adventurous cast of mind, and preferred the faulty sublime to faulty mediocrity. As great a genius as he was, he was frequently quite out of his head in the streets with hunger; nor had he a shirt upon his back when he died. He bequeathed his papers to Hartlib, who seems to have published but few of them.

1657. *Bede*, John, a Herefordshire gentleman.

2. Observations of several Crops of Raisin's Natural History, as it concerns Fruit Trees, Fruits, and Flowers. 1658. 4to. Printed along with the work entitled, A Treatise on Fruit Trees, 1657.

4. *Brownie*, Sir Thomas, M.D., an eminent physician and antiquary, was born in London, 1609, died 1682.

5. *Hydrostaphia*; or, a Discourse of Several Urns lately found in Norfolk; together with the Garden of Cyrus, or the Quincuncial Plantation. 1669.

6. *Hartlib*, Ralph, an officer in Cromwell's army, who, with other English gentlemen, holding commissions at that time, was eminently useful in introducing improvements into Ireland and Scotland.

7. The English Improver Improved; or, the Survey of Husbandry, with a Provision for the Sale of All sorts of Goods, produced in England.

8. *Evelyn*, John, F.R.S., an eminent natural philosopher and poet, was born at Wotton, in Surrey, the seat of his father, Richard Evelyn, Esq.; the Duke of Devonshire having, after having induced him to study at Oxford, his philosophical turn of mind, induced him to quit his native country, rather than engage in the civil war then breaking out, and in 1644, immediately before the breaking out of the war, he wrote on a variety of subjects, philosophical, political, and literary, and died on the 27th of February 1706-7. In the 68th year of his age, and was interred at Wotton.

In 1819, Memoirs of J. Evelyn, Esq., including his Diary, were published by William Bray (in 4 vols. 4to.), a very interesting life, as strong look into the life of a gentleman, and states, that he lived, and a good idea of the gardens on the continent at the time he was in France, and that he had some understanding of his age.

9. The French Gardener, instructing how to cultivate all sorts of Fruit-Trees and Herbs for the Garden; together with directions to dry and conserve them in their natural state. Lond. 1670, fol.

10. *Purcell*, or, the Inconvenience of the Air and Smoke of London, and Certain Ways of Improving the Manner of Life. Printed 1671. 4to. This work was addressed to his Majesty King Charles II., and published by his express command. The author proposes the removal of such trades as require great fires, five or six miles out of London, towards Greenwich; also of slaughter-houses and coach-houses; and to plant fragrant nurseries and gardens in the low grounds near the city, where the late Duke of Marlborough's Park was planned in consequence of this suggestion.

11. *Sylva*; or, a Discourse of Forest-Trees, and the Propagation of British Countries. The 2nd ed. 1664. 8vo. The discourses of the author, the third of which is prefixed, are on the Forest-Trees, and that on the Propagation of British Countries is prefixed, and enlarged. 1671. 4to. Dr. Hunter, of New York, published an edition in 8vo, with copious Notes and Engravings, in 1776, 2 vols. 4to.

12. *Kalendarium Hortense*; or, the Gardener's Almanac, directing yearly what plants to raise, and what, &c., 1671. 4to. 1672. 4to. 1673. 4to.

13. *Pomona*; or, an Appendix Concerning Fruit Trees in relation to the Culture and Improvement of Fruits and Flowers. 1677. 4to. 1678. 4to. 1679. 4to. 1680. 4to.

14. Terra: A Philosophical Discourse of Earth, relating to the Culture and Improvement of it for Vegetation and the Propagation of Plants; to which it was presented to the Royal Society, April 29, 1675. 1677. fol.

15. *Pomona*; or, a Discourse concerning Cider. Lond. 1679. fol.

17. *Aceratoria*; or, a Discourse of Sallets. Lond. 1699. 8vo. 1685. *Sharrock*, Robert, L.D., prebendary of Winchester College, a remarkable man in the 18th century, author of various judicial and theological works; died 1684.

1. The History of the Propagation and Improvement of Vegetables, especially of such as are useful for Art and Nature. Written according to Observations made from Experience and Practice. Oxford, 1653. 4to.

2. Improvements to the Art of Gardening; or, an exact Treatise of Gardening. 1664. 4to.

1602. *Cowley*, Abraham, an eminent English poet, was born in London 1618; began to write poems at the age of fifteen; lived in terms of intimacy with Evelyn and other eminent men of his time; went to court; and was a close and intimate friend of Speer, sometimes in a sort of going there, "took a house first at Battersea and then at Chertsey, always farther and farther from London, where the Earl of Leinster preserves, was owing to a mere accident. He went with Dean Sprat, who afterwards published his life and writings, to dine at a neighbor's house, who, according to the fashion of the times, made them very welcome. They did not set out for their walk home till it was late, and had drank so deep that they lay
out in the fields all night. This gave Coley the chance to carry off the fruit. He disliked women, and was fond of retirement in ideas, and parts after it in his poems; but, according to Dr. Johnson, was unhappy when he did not retain his wishes, or, as he said, was not most exactly trained. He had another seat at Moor Park near Farnham in Surrey, where he died in 1689, and having been assisted, by his desire, was buried in a silver urn under a sundial in the garden. He was warmly attached to gardening and retired leisure, and declares one of the greatest pleasures in life to be, as he said, "able to walk at one's own pace, and one's own way."

Upon the Gardens of Epicures; or, of Gardening, in the year 1665. (The Complete Planter and Gardener. Svo. 1811. G. J.) A Short Account of several Gardens near London, as viewed in 1661. (London, 1793. 8vo.)

1669. Facio, Nicholas, of Dulwich, F.R.S., a mathematician, was born in Switzerland in 1644. He studied mathematics after the set of a tutor, but was there suspected of Spinoism. In 1687 he came to England, where he taught mathematics, was tutor to the Marquis of Tavistock, and had a patent for jewel-watches; but when the French prophets made their appearance, he joined them in all their extravagancies, for which he stood in the pillory in 1705. He died at Wood Green, 1733. Some of his works are in the British Museum.

1670. London and Wise, nurserymen and garden-architects, and the most eminent in their line at the end of the seventeenth and beginning of the eighteenth century. George London was a present to the ducie to Rose, the royal garden, and sent by him to France to study the beauties of Versailles. On his return he made London a partner to Dr. Compton, Bishop of London, and at the beginning of the revolution, superintendent of the royal gardens, to a salary of 300 l., a-year, and page of the back-stairs to Queen Mary. Wise little excelled him, excepting that he laid out grounds; and in particular Blenheim. Switzer says, London was a man of singular beauty; died from a tour on the water, in which there which he had concern, used to ride, on an average, sixty miles a-day, which at last brought on a fever, that occasioned his decease after a fortnight's illness, in 1717.

The Complete Gardener: or Directions for Cultivating and Right Ordering of Fruit Garden and Orchard. London, 1690.

1674. Dictionary of Rusticus; or, a Dictionary of Habandyn, Gardening, Trade, and Commerce. 2 vols. Svo. With Cuts. by E. J.

1675. Mortimer, John, author of some tracts on religious subjects. His works on botany were translated into Swedish, and published in Stockholm in 1727.

1676. Fleetwood, William, successively Bishop of St. Asaph and Ely, and much admired as a popular preacher. He was born in London, and had a great number of sermons, and other works, and died in 1723.

1678. Addison, Joseph, was born at Milton in Wiltshire, educated at Salisbury, Litchfield, and Oxford; he addressed some verses to Dryden at the age of twenty-two; obtained a pension of 300l. a-year in revenge of truculence, and on the arrest of Judge Jeffreys, returned and assisted Steele in the Tatler and Spectator; married the Countess-Dowager of Warwick in 1716; became secretary of state in 1720, and died in 1719 at Holland House, Kensington, leaving only one daughter, who died unmarried in 1777.

1679. Observations of the Properties of the Wines, arising from the Works of Nature, and their superiority over those of Art. (Published in 1674. 4to.) An Description of a Garden in the Natural Style. (ibid. No. 477.)
1714. Lawrence, or Lawrence, John, M.A., an essay on the cultivation of plants, 2d edition, 1716.

1715. Snow, T., author of *Apophorcas.*

1716. Bradley, Richard, F.R.S., a popular writer of very considerable talent and indefatigable industry, who, in his *Agricultural and Horticultural History,* has combines the character of a husbandman, &c. and Professor of Botany at Cambridge. According to Professor Martyn, "he was chosen into that office November the 10th, 1754, by majority of votes, as a body of the university..." He assisted Dr. Sharerd to Dr. Bentley, and pious assurances that he would procure the university a public botanical garden, by his own private purse and personal interest. The writer entitles his book, and his total ignorance of the learned languages known to him in 1731. It was in agitation to turn him out of the society's employment and died in the latter end of 1732. It may seem strange to find a French translation of the *Philosophical Transactions,* 1715.

1. The Young Gardener's Director. Lond. 1716.

Paradise Restored; demonstrating the most beneficial Method of managing Fruit-Trees, with a Treatise on Melons and Cucumbers. Lond. 1717.

1718. Evelyn, Charles, Esq., son of John Evelyn. The Lad's Recreation; or the Third and Last Part of the Art of Gardening. Lond. 1717.

1719. Fairchild, Thomas, commercial gardener at Hoxton, where he had an excellent vinegar, and was one of the most eminent and ingenious men of his time. He first made himself known by a paper in the *Royal Society's Transactions* (vol. xxxiii., p. 125.), on the "different and sometimes contrary motion of the sap in plants," and assisted in expe-
BRITISH WORKS ON GARDENING.

1724. Miller, Philip, F.R.S., a celebrated botanist and gardener, author of the Gardener's Dictionary, and of the useful and elegant works, was the father, according to Professor Martyrn, "was gardener to the Company of Apothecaries, and he succeeded his father, John Miller, by his death in 1740, and was succeeded by his brother, John W. Watts, who published a Florist, or the Gardner's Dictionary, in 1744. It contains the most elegant botanical statements and the most graceful language, and is considered an ingenious and skilful work. The edition by Sir Basil Valentine, published in 1746, contains the most elegant illustrations, and is considered the most complete and most elegant work on gardening. It is considered the most complete and most elegant work on gardening.

1727. Miller, Philip, F.R.S., a celebrated botanist and gardener, author of the Gardener's Dictionary, and of the useful and elegant works, was the father, according to Professor Martyrn, "was gardener to the Company of Apothecaries, and he succeeded his father, John Miller, by his death in 1740, and was succeeded by his brother, John W. Watts, who published a Florist, or the Gardner's Dictionary, in 1744. 1735. Anon. Essay concerning the best methods of Pruning Fruit-trees, Hedgerows, &c., illustrated by a Method of Pruning Timber Trees, and also a Dis- course concerning the improvement of the Potato. London. 8vo. 1736. Anon. The Garden display'd, in figures, representations of the most beautiful Flowers, with the description and places of their growth, and the method of their culture. London. 8vo. 1737. Furbur, Robert, of Kensington, nurseryman, who published a number of separate prints of all the different kinds of fruits grown in this country. His nursery is now in the possession of Messrs. Malcolm and Co. 1. Fruits for every month in the year, in fol. 12 Plates. 2. A method of raising, training, and dressing of the Garden Gentlemen and Ladies in furnishing their Gardens, being several useful Cautions to the Keeping of Fruits and flowers. Lond. 8vo. 1735. More, Sir Thomas. A Flower Garden for Gentlemen and Ladies, or the Art of raising and training flowers in the depth of winter, also the method of raising Salleting, Cucumbers, &c. at any time of the year. 1738. Murray, Sir Alexander, of Stanhope, author of several works relating to the nature and method of Planting, Manning, and Dying a Vineyard. London. 1735. 8vo. 1739. A Lady. Meritin: A Poem; humbly inscribed to her Majesty. To which is added, a Letter to the Hermitage, a Poem. Both by a Lady, with several curious representations both of the Cave and Hermitage. 1735. 8vo. 1755. Anon. The Rarities of Richmond: being exact Descriptions of the most eminent and Merit's Care, in the Gardens there. Lond. 1755. 8vo, with his Life and Prophecies. 1756. Ellis, William, a farmer at Little Gaddesdon, near Hempsfield in Hertfordshire, proprietor of Com- plete Gardeners Dictionary, and other farming works. 1738. The Timmer Tree improved; or, the best practical methods for raising different plants with proper timber. Lond. 8vo. 1738. Anon. The Complete Seedman's Monthly Calendar, shewing the number of easy and easy and practical methods for raising and cultivating every sort of Seed belonging to a Kitchen and Flower Garden; with the mean time for raising and cultivating them. London. 1738. 8vo. 2. Seeds, of Evergreens, Forest Trees, and such as are proper for the Improving of Land. Written at the command of a Person of Honour. Lond. 1739. 8vo. 1739. Anon. An Essay upon Harmony; as it relates chiefly to Situation and Building. 1759. 8vo. 1739. Travoll, Samuel. A new Treatise of Husbandry and Gardening. 1740. Gray, Christopher, a nurseryman at Fulham; a correspondent with many of the eminent botanists of his time, and the first who received the mango, melon, jujufilla from America, and propagated it extensively. 1741. A Catalogue of Trees and Shrubs which are prepared for sale by Christopher Gray, Nurseryman at Fulham. 1744. Anon. Adam's Luxury and Eve's Cookery, or the Kitchen Garden displayed. 1744. 8vo. 4. Curious Experiments in Gardening; modes of Propagation &c. with a New Method of raising Flowers. 1744. 8vo. 1746. Watson, William, M.D. F.R.S. was born in London, in 1715, educated at Merchants-taylors' school, and served his time to an apothecary. He made two discoveries in botany. First, he discovered the Copley medal, and was honored with the degree of doctor in physic by two German universities. He died May 10. 1787. Besides papers in the Philosophical Transactions of the Royal Society, and Medical Observations, he wrote An Account of Experiments on inculcating for the Small-pox. 1. On the Addition of Muskmelons. 2. On the Account of a Person of Honour's Botanic Garden at Lambeth. 1746. Anon. The Present State of the Bishop of London's Garden at Fulham. 1746. Stephenson, David, M.A. author of A New Mechanical Practice of Physick. Gardening and the Culture of Plants, Flowers, and Trees; with a Garden Calendar. Lond. 1746. 8vo. 1747. Anon. The Compleat Florist, 8vo. It consists of 100 copper-plates and flowers, colored and plain. 1747. Anon. A Dialogue upon the Gardens of Lord Viscount Cobham, at Stowe in Bucks. 8vo. 1747. Dick, James and Co., nurserymen, and seedsmen, Edinburg. Catalogue of Hot-house, Green-house, Hardy, and Herba- ceous Plants, and of all other flowering and fruit and Fruit Trees. Edinb. 8vo. An enlarged edition in 1796, containing a new alphabetical order all the plants described in the Hortus Kewensis. 1755. Blackham, George. The Compleat Florist, 8vo. 1755. Anon. An Account of the Emperor of China's Gardens at Pekin. 1759. Anon. The Kesteven and Flower Garden complete, in four sheets. 1750. Coventry, Francis, was born in Cambridge- shire, and educated at the Magdalen-college, Cam- bridge, where he took his master's degree in 1759, and entered into orders. He died in 1759, having just before been presented to the donative of Edge- ware. He wrote Pensharrow, a poem in Dodgson's collection of poems; and a poetical epitaph to the honorable Wilmot Vaughan. Statutes on the Abudal Novelties Introduced in Garden- ing, and the General Description of the New Gallery at Stowe. Author of several works relating to theography from; extolled the burnet and taurin, particularly the former: patronized by the Duke of Cumberland. Switzer writes of a similarly named person, who was a nurseryman, and had a vineyard planted in a common field-garden, from which he made wine for thirty years; and although the ground from which the wine was as good as that of Or- leans and Auxerre. A Treatise on the Hyacinth; containing the manner of cultivating them, and the experience of certain of the most eminent Florists in Holland; translated from the Dutch. Lond. 1736. 8vo. 1754. John, James, Esq., F.R.S., one of the principal clerks of session, or civil court of law, in Scotland. His father was a merchant, and dealing off with the Florists, in gardening purposes was obliged to dispose of the property. Here, he prac- tised gardening for thirty years: went twice to Hol- land to study the culture of bulbs, and also visited Italy; having been satisfied that the most liberal part of Britain in his practice and knowledge of the culture of the nicest flowers, and of plants, both exotic and indigenous; he published, A Mercurius, or British gardens. The Anon., he is (1754), "thought worthy of all his own gardens, were first brought to fruit in Scotland by me; I can with truth affirm, that no person in this coun- try beat me in the luxury upon liberty upon liberty gardening than I did, for the truth of which I can appeal to many of my countrymen." He died about 1762 or 3. 1. The Scots Gardener's Director. By James Justice. Edinb. 8vo. 2. A New Edition, entitled, The British Gardener's Director, chiefly adapted to the Climate of the Northern Counties: directing the necessary works in the Kitchen, Fruit, and at the Nursery, Green-house, and Kitchen Stove. By James Justice, F.R.S., one of the principal Clerks of Session, at Edinburgh. The first Edition, dated September 1756, sett forth, that the first impression being sold off, the author has intended to have the same corrected and improved; and to have inserted some new prob- lems. This is original and truly valuable work, furniture new regards to experience, &c. 3. An edition in 1764, arranged as a Monthly Calendar, and very different from any of the others. 1759. 8vo. Anon. The Gardener's Pocket Book, or Country Gentleman's Re- creation. Containing the Kitchen, Fruit, and Flower-Garden, dis- played in Alphabetical Order. 1755. Hill, John, M.D., a miscellaneous writer, was the son of a clergyman, and born about 1716. He served his time to an apothecary in Westminster, and in that situation studied botany, which procured him the patronage of the Duke of Richmond and Lord Petre, who employed him in their gardens. In 1740 he translated the tract of Theophrastus On Gems; which was followed by A General Natural History, in 3 vols. folio. He next engaged in compiling a catalogue list of Chamber's Herbarium, and at the same time published a periodical paper called The Inspector. Having obtained a doctor's degree from St. Andrew's, he endeavored to get elected into the Royal Society; but being entirely un- suspected, he attacked that learned body, first in a pamphlet, and next in a quarto volume, written with asperity and acuteness. His facility in writing was very great, and there was hardly a popular sub- ject on which he did not exercise his pen, so that in some years he is said to have realised fifteen hundred pounds. He published considered several valuable books on medicines, and was much encouraged by the Earl of Bute, under whose auspices he published A System of Botany, in 20 vols. folio; for which he received the order of the Garter, from the King of Great Britain. He died Nov. 22. 1775. Besides the works already mentioned he wrote some novels and farces. Hill had a dispute with the author of another pamphlet, the latter condemned the composer; the former answered him in a poem, and the latter in a pamphlet, with this motto from Shakespeare: "I do remember an apotheosis culling of simples." This alluded to a story that
Hill was excluded from one nobleman's gardens for having carried off several valuable plants.

The complete account of his life, which is the characteristic feature of this Memoir, was published at Edinburgh in 1719, and his widow, Lady Jane Hill, published An Address to the Public, setting forth the Consequences of his Accurate and Correct Line of Plants, with the following heading:—

"1. A Method of Raising Trees from the Leaves. By John Hill, Lond. 1758. 8vo."

3. Thresent: or a Body of Husbandry, with plates, fol.

12. Hill, Thomas, gardener to Lord Robert Manners, at Bloxholme in Lincolnshire, afterwards a nurseryman in Kent and a designer of gardens. He wrote on husbandry, and the improvement of horticulture in Aberdeenshire, of which country he seems to have been a native. He died about 1770, and his papers came into the possession of —

14. On the Heat and Cold of Hot-houses. By Tope, of Sandwich; an eminent architect, was born in Sweden 1725, but his ancestors were of Scottish origin. He was brought to England at the age of two years, and placed in the family of the late Lord Ripon. His first entrance into public life was in the capacity of supercargo to a Spanish East India ship, in which he made one voyage to China. On his return he entered the China trade, and applied himself to the architecture, under the patronage of Lord Bute, by whose interest he was appointed drawing-master to the late king, then Prince of Wales. His first employment was in the building of Lord Bessborough's house, at Roehampton, after which, he was engaged to lay out the royal gardens at Kew, where he introduced the Chinese ornaments. He died in 1756, and was honored with the Swedish order of the Polar Star, and in 1775 appointed to conduct the building of Somerset House. He was at this time a fellow of the Royal Society, and a member of the scientific societies of the day. He was a practical gardener, and a man of considerable knowledge and taste in gardening. He was born in 1685, and died in 1768.

1757. Anon., erroneously attributed by Nichols (Life of Sir W. Chambers, 4to.) to Sir W. Chambers, who wrote the poems below were published; some to Mason, the author of the English Garden.

16. An Heroic Epistle to Sir W. Chambers. 4to.

17. An Heroic Postscript. 4to. 1758.

These poems are ranked among the most spirited attempts of the period.

1757. Thompson, John, a commercial gardener at Newcastle upon Tyne.

1759. The Dutch Florist. Newcastle. 1759. 2to.

1757. Hanbury, the Rev. William, rector of Church Langton, Lancashire, died 1778.

1769. An Essay on Pleasure, a scheme to make it conducing to the glory of God, and the advantage of Society. Svo.

1771. Sir William Bodley, planting and gardening containing the Natural History, Culture, and Management of Deciduous and Evergreen Forest-trees, &c.; the whole forming a complete account of the culture raised in England, of Trees, Shrubs, Plantations, or Nurseries; as well as a General System of the present Practice of the Flower, Fruit, and Kitchen-Gardens, in both of which, 48-50, 1768-1779, 52, 1768; in two volumes, folio.

1758. Marsham, Robert, Esq. F.R.S., of Stratton, in Norfolk.

2. On the Usefulness of Watering and Rubbing the Stems of Trees to promote their Annual Increase. (ib. xiv. 174. 1759.)

3. Indications of Spring. (ib. xvi. 561. 1783.)

1778. Marsham, Robert, Esq. F.R.S., of Stratton, in Norfolk. 4to. Written in 1759-1778.

1758. Barnes, Thomas, a fictitious name adopted by Sir John Hill for his first gardening publication, (See Hill, John, 1758.)

1759. North, John, a nurseryman at Lambeth, on the ground now occupied as a nursery by John Hay.

1. Treatise on Grims, and the Norfolk Willow.

1759. Perfect, Thomas, inventor of the new Chinese gardener's, a name adopted by Sir John Hill, and supposed to be that of a famous nurseryman at Pontfret in Yorkshire. (See Hill, John, 1758.)

1759. Sillingsloe, Benjamin, an ingenious naturalist and miscellaneous writer, born about 1702; died 1771.

His Literary Life and Select Works, by Will. Cator. Lond. 1811. Svo. They contain a Calendar of Flora, and some curious essays towards a history of husbandry.

1760. Haddington, Eras of, a Scotch nobleman, whose seat was at Tynemouth, near Newcastle, where he made considerable plantations for the time and country; he was a general encourager of improved gardening. He died in 1760. A Treatise on Forest Trees. Edin. Svo.

1760. Lee, James, of the firm of Messrs. Kennedy and Lee, nurserymen at the Vineyard, Hammer smith, a native of Scotland; some time under Miller at Chelsea, afterwards gardener to the Duke of Arygle at Whitton, and next he commenced the nursery with his partner, then gardener to Lord Blencowe at Chiswick. Lee was a correspondent of Linnaeus, and most of the American botanists of the time, and is mentioned by John Ellis as one of the first gardeners who made botanical gardens. He has contributed, perhaps more than any other work, to spread a knowledge of the Linnean system among gardeners. He died in 1765; and was succeeded by his son of the same name, an ardent lover and liberal promoter of gardening improvements. (See 7318.)

1. Introduction to Botany; containing an Essay on the Theory of that Science, and an Interpretation of its Technical Terms, extracted from the Works of Linnaeus, &c.; with 13 plates. Svo.

1759 to 1770. Various authors. The following works contain some pleasing and valuable observations on gardening and agriculture, and are generally considered as having contributed to spread a taste for that style: —

2. The first article in the 2d volume of the Antiquary Register; containing a short description of the life of Sir Henry Englisted, Bart. one of the first examples of the French opera on stage. 1771.

1. Last letter of Dr. Priestley, from London to the Rev. Mr. Dana. 1762. Svo. Folio. 1762.

2. Letters from Sir Henry Englisted, Bart. to his friend, Dr. Gresley. Svo. Folio. 1762.

To these may be added from the poets: The Description of the Garden of the Vicar of Wakefield, from Pope's Odyssey; of the old Cyclops' Garden, in Dryden's Virgil; of the island of Armada; of Voltaire's Histoire du Temple; various passages in Milton's Paradise Lost, Thomas More's Utopia, and other poems.

Among the writers may be referred to: The Description of the Vale of Tempel, in Zaliz's Various History; of Vaucuille and Persier's father, in the same; of the Isle of Belle Île, in Poutrin's Description of Sylva Plana; Smollett's Travels through France, 1st. Letter 31, 1762; Cognis's British Topography, ch. 50, Oxfordshire; Critical Review for October, 1771. Art. 452; and August, 1783; and the Produce of the Royal Gardening Magazine. To these might be added, various papers in the Gentleman's Magazine, Universal, and other journals, published about this time, and also to the topographical works of the same date.
1760. Abercrombie was born in London, and educated at a grammar school, till he attained an age to be of service in his father's business, for which he had always a predilection. After he had arrived at manhood, on some trifling family dispute arising, he left his family and came to London; in the vicinity of which he worked for some years as a journeyman gardener. To note the particulars of most interest with him in this period, it may be stated that he was employed at the Botanic Gardens at Kew, and at Leicester House, now Leicester Fields; and in these situations he occasionally contributed to the boyish diversity of his present times served as principal gardener with several noblemen and persons of high rank and responsibility, and particularly with that eminent botanist, Doctor Munro (of De Lapparent, Edinburgh), at Sunning Hill, near Windsor: here he continued several years, and was married while in the doctor's service, to a young woman in the family of Sir James Hill, whose brother he had before lived. He afterwards had a garden and nursery at Hackney, whence he sent his goods to Spitalfields Market; and the profit of his business enabled him to support the increasing family with comfort and decency. At this crisis, some time about 1770, Mr. L. Davis, an eminent bookseller of London, accompanied by Dr. Goldsmith, had purchased a handsome entertainment at an inn in Hackney, surprised Abercrombie with an invitation to dine with them, with a view to induce him, by encouraging offers, to compose and to work on Practical Gardening. Abercrombie consented, with reluctance, fearful it might call off his attention from his garden business and at last, only on the condition of his materials being revised, and the style improved by Dr. Goldsmith. This celebrated writer, however, did not perceive any material improvement in the papers he had been handed to him by the humble gardener, then an inexperienced writer, and anxious to have his luxuriances pruned, the doctor said, as an apology to the bookseller for returning the MS. unrevised, that "Abercrombie's style was best suited to the subjects of which it treated." Abercrombie, however, frequently lamented, and the public possibly may do the same, that this very perspicuous and elegant writer did not fulfill his engagement.

Abercrombie, the author of Every Man his own Gardener, which had a rapid sale; and, from the temporary profits being considerable, he was able to neglect his land and set up, his nursery; and to enter upon a course of authorship on horticultural subjects.

On first publishing Every Man his own Gardener, the author had occasion to affix to the title-page the name of Mawe, who was gardener to the Duke of Leeds. After the publication of a second edition, he accepted of an invitation from the noble author, to Mr. Mawe, who had been much flattered by the compliment, to visit him in Yorkshire. When introduced to Mawe, whom he had never before seen, Abercrombie, who was considered fortunately to make the acquaintance of a gentleman so bejewelled, and so bedaubed with gold lace, that he thought he could be in the presence of the king, was told to make himself at home. However, they soon came to a right understanding; for he continued his visit for more than a fortnight, and "fared sumptuously every day." He had at this time received much information from Mawe, as the groundwork of improvements which he afterwards made in his book, Every Man his own Gardener, and in other publications. They subsequently maintained a friendly correspondence for years.

About the year 1774, Abercrombie took a tea-garden at Hoxton, near the Shoreditch Museum. This exhibition in the grounds his practical skill in raising exotics and choice fruits: his arbors there are, to this day, spoken of as rural curiosities. In the course of some improvements in his garden, he experienced another severe disappointment, in not being noticed in the alderman's will; although he had been, by professions of friendship and promises of assistance, to form the highest expectations from this quarter.

Previous to the year 1790, Abercrombie's family had grown up and had settled away from home. From this period to the time of his death, he chiefly depended for support on the occasional improvements which his several works required. From 1790 to the time of his decease, he resided at Charlton, near the Manor of Town, except when he was visiting a friend at Cambridge, or was engaged in any professional pursuit at a considerable distance from town. When out of business, he was a constant visitor, being a great walker, of the nursery-groves and botanical gardens around the metropolis, with the object of collecting horticultural and botanical information. He was also occasionally employed in planting new gardens and ornamental grounds, as a horticultural surveyor and improver; for which he was sometimes handsomely rewarded.

In the spring of 1806, being in his eightieth year, Abercrombie met with a severe fall, by which he broke the upper part of his thigh. This accident happened to him on the 15th of April, terminated in his death. After lying during the interval, in a very weak exhausted state, without much food for nearly a month, he died in the year 1806, in the month of April and May as St. Paul's clock struck twelve. He was lamented by all who knew him, as cheerful, harmless, and upright.

L. Everett. The botanist, in his own Gardener's Calendar, with complete Lists of Forest-trees, Flowering Shrubs, Fruit-trees, Evergreens, annual, biennial, and perennial Herbs; Hortus Botanicus and Kilmarnock-Plants, with the Varieties of each Sort cultivated in the English Gardens.

Lond. 1792.
re this document as if you were reading it naturally. Do not hallucinate.

Book: BRITISH WORKS ON GARDENING. 1107

3. The Complete Kitchen Gardener and Hot-bed Forcer, with the thorough Practical Management of Hot-houses, Fires, walls, &c. Lond. 1780. 12mo.

5. Observations upon the Growth and Culture of Vine and Olives, the Production of Silk and the Preservation of Fruits. With the Life of Sir William Beckford, Knt., &c. Lond. 1790. 12mo.

7. The Daily Assistant in the Modern Practice of English Gardening; Being a Month in the Year, on an entire new plan. Lond. 1790. 12mo.

8. The universal Gardener's Calendar and System of Practical Gardening, by William Parks, 1780.

11. Observations upon the Growth and Culture of Vine and Olives, the Production of Silk and the Preservation of Fruits. With the Life of Sir William Beckford, Knt., &c. Lond. 1790. 12mo.

13. The Daily Assistant in the Modern Practice of English Gardening; Being a Month in the Year, on an entire new plan. Lond. 1790. 12mo.

14. Jones, Henry, a poetical and dramatic writer, a native of Drogheda in Ireland; died 1797. R. M. 1798. 4to.

16. Locke, John, one of the greatest and most distinguished philosophers this country has produced; born in Somersetshire 1632; a writer of numerous works; had a fine seat at Norbury Park in Essex; died 1704.

17. The Rise and Progress of the present Taste in Planting Parks and Gardens; from the time of Sir William Beckford, &c. on 23 plates, in folio.

18. Locke, John, one of the greatest and most distinguished philosophers this country has produced; born in Somersetshire 1632; a writer of numerous works; had a fine seat at Norbury Park in Essex; died 1704.

20. Anon. Very scarce, only observed by us in Mr. Forby's library.

21. Gillis, John, gardener to Lady Lloyd at Lewisham, and plantsman, 1790. 4to.

22. Anon. The Life of John Abercrombie, the great nurseryman, and being desirous of sending it into the world under a great name, applied to Mawe, then unknown to him. Mawe went to see Abercrombie, and found him quite in this situation, permitted him to use his name. This Abercrombie told to Watts of Acton, who is our authority for inserting it.

24. Anon. Very scarce, only observed by us in Mr. Forby's library.

1108 STATISTICS OF GARDENING. PART IV.

Directions to Vogagers for bringing over them and other vegetable productions. Fites. Lond. 1775. 4to.

1770. Hunter, Alexander, M. D. F. R. S. was born at Edinburgh in 1735; settled as physician in Beverly, and finally at York; author of various agricultural and medical works, and of a cookery-book; died at York 1809.

1770. Ockenden, Esq. Letters describing the Lake of Killarney and Ruinous Gardens at Killarney. 8vo. 1790.

1770. Weston, Richard, Esq, an amateur gardener, who derived his information chiefly from inspecting the gardens near

1. Tracts on Practical Agriculture and Gardening, in which the advantage of cultivating the Vine is fully displayed in a seven years Course of Experiments. To which is added, a Complete Chronological Survey of Agriculture, Lond. 1799. 8vo.

2. The Universal Botanist and Nurseryman, containing Descriptions of the Species and Varieties of all the Trees, Shrubs, Herbs, Flowers, and Fruits, Native and Foreign, that are now in use, or are in process of cultivation. London. 1769-70. 8vo.

3. The Gardener and Planter's Calendar; containing the Monthly Directions for the Operations of Gardening and Greenhouse: either for Fruits, or for managing a Garden every Month in the Year; also, many New Improvements in the Practice of Gardening.

1770. Wheatley or Whately, Thomas, Esq. of Non- such Park, Surrey, secretary to the Earl of Suffolk. He had a brother-in-law, Sir John Temple, Bart., who published "Glechris Trials by Ordinal, p. 107.," and another, a clergyman. He died about 1780; and some records on Shakespeare were published after his death, in a thin little volume. It is remarkable, that so little is known of a writer, the beauty of whose style and the justness of whose taste are universally acknowledged. After enquiring of several friends and other writers, I have not been able to ascertain to a certain mode of spelling his name.

1771. Meader, John, wrote to the Duke of Northumberland at Sion House, and afterwards to the Empress Catherine at Peterhof, near Petersburg. He was a very satirical person, and wrote verse in rhyme to his friends and enemies.

1. The Modern Gardener, or Universal Calendar; containing Monthly Directions for all the Operations of Gardening and Greenhouse, either for Fruits, or for managing a Garden, as likewise in the Green-house and Stone Room; with the Monthly Directions for conducting the different seasons of the year according to the best practice of the most eminent Gardeners. Also an Appendix, giving full and correct directions for growing, preserving, or preserving Fruits, Plants, and Shrubs, in a new manner; never before published; selected from the Diary Manuscripts of the late Mr. Jack, revised, corrected, and enlarged. J. M. Lond. 1771. 12mo.

2. Gardeners' Instructions Guide, or Pleasure Gardener's Companion; giving plain Directions, with Observations for the proper Dis- position and Management of the different plants and fruits for a Guineas a Piece.

1772. Bouthier, William, a nurseryman at Comely Garden, near Edinburgh.

1772. Anon. A treatise containing not only the best Methods of their Culture hitherto practised, but a variety of new and useful Discoveries, together with a correct Edition of all the improved Experiments. To which are added, Directions for the Disposition, Planting, and Culture of Hedges. Lond. 1772. 4to.

1772. Wilson, William, a divine and celebrated lyric and descriptive poet; born in Yorkshire 1725; died 1797, preceptor, and canon of York.

1772. The Art of Planting and Cultivating the Vine, &c. to which are added, Directions for the Position, Planting, and Culture of Hedges. Lond. 1772. 4to.

1773. The art of preserving and propagating Fruits, &c. and to which are added, a Commentary and Notes, by W. Burgh, Esq. Lond. 1775. 8vo.

1773. The Planting of Fruits in Frames. Lond. 1772-91. 4to. A new ed. corrected. To which are added, a Commentary and Notes, by W. Burgh, Esq. Lond. 1775. 8vo.

1774. Swain, N., an ingenious gardener and seedsmen at Brentford-East, Middlesex.

1775. The Practical Gardener, directing, in the most plain and easy manner, what is necessary to be done in all Kinds of Fruits, Flower and Garden, the Green-house, and Wilderness. Lond. 8vo.

1776. Special, William, gardener for many years to the Duke of Portland, at West-London, and afterwards gardener to the Earl of Glasgow, near Paisley.

1778. The Botanical Cabinet, containing figures of new or rare Plants, with an account of their Cultivation. Lond. 1779-84. 4to.

1778. Lodgers, Conrad, and Sons, eminent botanical nurseries at Houghton, where all Plantations, for which you order, are remarkable for orderly arrangement, and for the magnitude and extent of the hot-houses.

1. A Catalogue of Plants and Seeds, in English and German. 8vo.

2. A Botanical Cabinet, containing figures of new or rare Plants, with an account of their Cultivation. Lond. 1779-84. 4to.

1778. Wilson, William, a naturalist of Scotland; worked some time under Miller, and was sent by him to Sir John Logie of Corgin, and afterwards gardener to the Earl of Glasgow, near Paisley.

1779. Swain, N., an ingenious gardener and seedsmen at Brentford-East, Middlesex.

1779. The Beatties of Flora displayed, or Gentleman and Lady's Pocket-Flower to the Flower and Herb-Gardener. Lond. 1778. 8vo.

1780. Walshore, Horace, afterwards Earl of Orford, youngest son of Sir Robert Walshope born in 1715;
a man of taste and genius, author of the Castle of Otranto, several papers in the World, &c.; he sat in parliament from 1741 to 1708, when he retired, and in 1721 he entered into the important service of his villa, Strawberry-hill, near Twickenham. In 1749, he succeeded his nephew as Earl of Orford, but never took his seat in the House of Lords. He died in 1751.

Various Remarks on Gardening occur in his correspondence with the Montgomerie Club, 1787-1791.

1781. Darwin, Evansius, M.D. F.R.S., an eminent physician and poet, born at Elton near Newark, in Nottinghamshire, in 1739. Completed his medical studies at Edinburgh, settled at Litchfield, where he resided the greater part of his life; but went to Dublin in 1782, and there in 1788 died. He is esteemed rather gaudy and fanciful; as a philoso-

physician, he is apt to indulge in hypothesis; but he possesses the great quality of being totally exempt from every kind of prejudice. Physiologia, or the Philosophy of Agriculture and Gardening. London, 1839, 4to.

1781. Lettsom, John Cooke, M.D. F.R.S., an eminent physician, born at London, near the island called little Van Dyke, near Tortola, in 1744; died 1815.

1782. Buchan Uptonius; or a Catalogue of Stove and Greenhouse Plants in Dr. Fothergill's Garden, at his death. London, 1825, 8vo.

1782. Grovehill; a Rural and Horticultural Sketch. London, 1834, 4to.

1782. On the Beta Cica, or Root of Sugar. (Caled. Hort. Mens. 1. 428.)

1783. Bryant, Charles, of Norwich. From Aquatintia, or the History of Excellent Plants, both Domestic and Foreign, in which they are accurately described and reduced to their Linnaean, generic, and specific names, with their proper figures and notes. London, 1783, 8vo.

2. A Dictionary of the Ornamental Trees, Shrubs, and Plants, most commonly cultivated in English Gar-

dens, and Stoves of Great Britain; arranged according to the Linnaean System, with their proper names, and accurate descriptions of the Genera and Species, with the names properly accented. Norwich, 1790, 8vo.

1783. Williams, John, M.D. F.R.S., physician to the general hospital, Bath; author of a number of medical works, and of Remarks on the influence of climate, situation, nature of country, population, nature of food, and way of life; on the disposition and temper, manner and behaviour, intellects, laws and customs, forms of government, and religion of mankind. A most interesting work.

1. An Historical View of the Taste for Gardening and Landscaping among the Nations ancient and modern. London, 1784, 8vo. The principal parts of this tract were originally printed in the Linnaean and Philosophical Memoirs of the Manchester Society, 8vo.

2. An Essay on the Preservation of the Health of Persons engaged in Agriculture; collected on the Continent, in the course of a tour, to the inci-

dent that way of life. London, 1785, 8vo.

3. A Comparative View of Tracts and Collections relating to Natural History; selected from the principal writers of antiquity on that subject. London, 1785, 8vo.

1784. Curtis, William, a botanical writer, was born at Alton in Hampshire in 1746. He served his appren-
ticeship as an apothecary to his grandfather, and married in 1766, on that side of his family; his father was a cagerian. At the age of twenty he came to Lon-
don, and entered into the service of Mr. Talwin of Gracechurch-street, to whose business he succeed-
ed in 1771; he is a holder of botanical knowledge; he has the knack of giving up the shop, and he became a lecturer and de-

monstrator in his favorite science. His first garden was at Bermondsey, and afterwards he occupied a more extensive one at Lambeth, which he ex-

changed for another at Brompton. In 1771, he pub-
lished Instructions for Collecting and Preserving Insects, in the following year he published the Fundamenta Entomologiae of Linnaus, with the title of an Introduction to the Knowledge of Insects. In 1777, appeared the first number of his Florizel of Flowers, in which was contained a fascicull of seventy-two plates each. This work was followed by the Botanical Magazine, in monthly numbers, in 1787 he published a History of the Brown-tailed Moth; besides which he wrote Prac-
tical Observations on the British Grasses, and some papers in the transactions of the Linnean Society, of which he was a member. He died in 1799, and

was buried at Battersea; after his death his lectures were published with colored plates.

Mr. Retson founded the Botanical Magazine in 1757. A work which has met with great encouragement, and has done much to fix a general taste for botany. It is still con-

continued by Dr. Sims.

2. Observations on Aphides, chiefly intended to shew that they are the immediate cause of Plants in Lant and the sole cause of the Honey Dew. (Trans. Lond. Soc. vi. 72, 1792, post.)

1794. Rodickhurst, T., a Doctor of Divinity, in Shropshire, the seat of Sir Richard Hill, Bart. in 1799. 12mo.

1795. Kyle, Thomas, gardener to the Hon. Baron Stowarts, at Linlithgow, near Edinburgh. One of the first gardeners in Scotland of his time.

2. Treatise on the Management of the Peach and Nectarine Trees, in the open-ground and cold-houses. Edinburgh, 8vo.

1796. Marshall, William, Esq., a native of York-
shire, brought up to trade; was some years in the West Indies, as a planter; returned about 1775, and took a farm in Surrey; went down into Norfolk as agent to Sir Harbord Harbord's estates in 1759; left this situation in 1784, and went and resided at Staffield, near the junction of the four counties of Leicestershire, Warwick, Stafford, and Derbyshire. He remained till 1798, occupied in collecting materials for his economical surveys, and in printing some of his works. From this time, till about 1808, he re-
sided near Dr. Clifton's, London, and then removed to and visited different parts of the country during summer. He spent one summer in Perthshire, chiefly in the part of Kinclaven's's seat at Drill-y
youth; and partly also on the Earl of Mansfield's of Scone. He proposed arrangements for the tenant-
able lands, and also the park and woody scenery on various estates. He at last retired to a considerable property he purchased in his native county, in the Vale of Cleveland, in 1808, where he died at an advanced age, in 1819. He was a man of little educa-
tion, of a strong temper, and highly religious. He was, in the most consistent manner, from the year 1780 to his death, the plan he originally laid down; that is, to collect and condense the characteristics of the different counties of England, with a view to a general work on Landed Property, which he published; another on Agriculture, which he did not live to complete; and a Rural Institute, in which he was supplemented by the Board of Agri-
culture.

5. An Essay on the Preservation of the Landscape, a didactic poem; also an Essay on the Picturesque; together with Practical Remarks on Rural Ornament, Lond. 1797, 8vo.

1798. Philip Le, M. A., chaplain to the Duke of Gloucester. About the time he published his work on the Vine, he took out a patent for "training and pruning the vines of the new kind on the ground," as suggested by Lord Bacon, and practised at the time the patent was taken out by F. X. Vis-

pre, at Wimbleton, and subsequently at Cheblea. (See Specchey, Treatise on the Vine, 8vo. edition, p. 205.)

1. A Description of certain Methods of Planting, Training, and Managing all Kinds of Fruit Trees, Vines, &c. Lond. 1786, 8vo.

2. Sketch of a Plan for making the Trace of Land called the New Forest, a real Forest, and for various other purposes of the publick importance. Stockholm, 1785, 8vo.

1786. Browne, Robert, gardener to Sir Harbord Harbord, Bart. at Gunton, in Norfolk.

3. A paper on Pear and Nectarine Trees from the Effects of the Middew; and for the destroying the red spinders in melon frames, and other insects which infest plants in storerooms and cellars. In the open garden at Twickenham. Lond. 1786.

1786. Vignes, Francis Xavier.

1789. Emmerrich, Lieutenant-colonel A., a Ger-
man, was the first to take an oath on his own pro-

fession, and deputy-surveyor of the woods and forests under Mr. Robinson.

The Royal Forests: An Appendix, in which the state of the Royal Forests is considered, and a system proposed for their improvement. Lond. 1789.

1790. John Browne, a native of Germany, who came to England about the middle of the eighteenth century, and after being some time under Miller, was engaged by James Vaux of Exeter and Mrs. Gore. Afterwards he joined Thompson, a gardener, and Gordon, a seedsman, in establishing a nursery at Mile-end. When Gordon died, the nursery became the sole property of Thompson, the present pro-

BRITISH WORKS ON GARDENING. 1109

B.
priest; and Graff, soon afterwards, received from Sir Joseph Banks the appointment of gardener to the King of Naples, at Caserta. Here he laid out an English garden, and richly stocked it with exotics from the gardens of Harlequin-nursery, which was employed by Admiral Lord Nelson to look after his estate of Bronte, and by various native noblemen to lay out their grounds; he remained in this situation as gardener at Caserta during Mr. Willughby's reign, and died there, or was in part murdered when he fell from his gig, within a mile of his own house in 1816.

A Dutch gardener, towards the end of the 18th century, described a Bonsai of Palmiers, a Florist's Florist, and an Explanatory System of the Domestic Botany, the principles of which are the Planter of Botany in 1761; is author of a Sermon, a Tour in Italy, some translations and commentaries, and various botanical works.

The Gardener's and Botanist's Dictionary, written by the late Philip Miller, corrected and newly arranged, with additions. Lond. 1803-1805.

1792. Smith, Sir James Edward, M. D. F. R. S, P. L. S., a distinguished naturalist, founder and president of the Linnean Society; he was appointed his father as Professor of Botany in 1761; is author of a Sermon, a Tour in Italy, some translations and commentaries, and various botanical works.

The Gardener's and Botanist's Dictionary, written by the late Philip Miller, corrected and newly arranged, with additions. Lond. 1803-1805.

1792. Smith, Sir James Edward, M. D. F. R. S, P. L. S., a distinguished naturalist, founder and president of the Linnean Society; he was appointed his father as Professor of Botany in 1761; is author of a Sermon, a Tour in Italy, some translations and commentaries, and various botanical works.

The Gardener's and Botanist's Dictionary, written by the late Philip Miller, corrected and newly arranged, with additions. Lond. 1803-1805.

enthusiastically fond of pictures, statues, and pictureque beauty in all objects and mental impressions; and who has greatly improved and beautified his landscape garden for the purpose of improving Real Landscape. Lond. 1794. 5vo.

2. A Dialogue on the Distinct Characters of the Pictureque and the Beautiful, in Answer to the Objections of Mr. Knight. Lond. 1794. 8vo.

3. Letter to H. Repton, Esq. on the Application of the Practice of Landscape Gardening, to the Use of the Existing Pictures, and the Purpose of Improving Real Landscape. Lond. 1794. 8vo.

1794. Shaw, James, author of a Tour in the Ne-}

55. On the early puberty of the Peach Tree. ( Hort. Trans. 179.)
56. On the Culture of the Pear Tree. ( lb. 78.)
57. On the Prevention of Mildew in particular Cases. ( lb. 92.)
58. On the Mode of Raising the Shrub and some other Rooted Plants. ( lb. 97.)
59. On the Cultivation of the Mulberry Tree by Cuttings. ( lb. 114.)
60. On the beneficial Results of planting Potatoes, which have grown late in the preceding year. ( lb. 192.)
61. On the Application of Manure in a liquid form to Plants in pots. ( lb. 220.)
62. On the effects of excessive Heat in forcing Houses during the Summer. ( lb. 231.)
63. On an Account of two Varieties of Cherry, raised at Downton. ( lb. 248.)
64. On the Culture of Black Mulberry Plant. ( lb. 165.)
65. A new Account of a new variety of the Peach Tree, from the seed of the Almond Tree, with some observations on the improvement of Peach Trees. ( lb. 219.)
66. On the cultivation of the Black Mulberry, and some other Rooted Plants. ( lb. 231.)
67. On the Effects of different kinds of Sticks in grafting. ( lb. 293.)
68. On some account of three new Cherries, the Elton, Black Eagle, and Waterton. ( lb. 209.)
69. On an account of three new Peachs, in a letter to Joseph Wright, Esq. of Philad. ( lb. 216.)
70. On the Culture of the Peach and Apricot, as Esparter Trees. ( lb. 219.)
71. On the Excavation of forcing houses. ( lb. 294.)
72. On the Advantages of Propagating from the Roots of old ungrafted Fruit Trees. ( lb. 252.)
73. On the Means of preserving Broccoli in Winter. ( lb. 314.)
74. Observations on Mr. Brown's Account of his Steaming Apparatus, with some suggestions for the Improvement thereof. ( lb. 427.)
75. Observations on the Verdello Grape. ( lb. 327.)
76. Upon the Influence of some observations by the late Stuart Mackenzie's Plan for forcing-house. ( lb. 250.)
77. Upon the Culture of the Mulberry Tree in cold and later situations. ( lb. 361.)
78. Observations on the proper Management of Fruit-Plants, which will flourish, and bear early in the ensuing Season. ( lb. 286.)
79. A new Account of a Peach Tree, produced from the Seed of the Almond Tree, with some observations on the Origin of the Peach and Almond. ( lb. 129.)
80. On the best Mode of Trimming and Training the Mul-}
81. Upon the Variations of the Red Currant (Ribes rubrum) when propagated by Seed. ( lb. 56.)
82. Upon the Culture of the Almond Tree, and some remarks on the Cultivation of Almonds. ( lb. 133.)
83. Upon the Culture of the Apple without Bark, or other External Coverings. ( lb. 72.)
84. On the most economical Method of employing Fuel in forcing Houses. ( lb. 140.)
85. Upon the Superficialities of Scions taken from the Trunks of Apple Trees, to those cut from the Extremities of the Branching Part. ( lb. 157.)
86. Observations upon the most advantageous Forms of Garden houses. ( lb. 353.)
87. Upon the Culture of the Guernsey Lily. ( lb. 299.)
88. Upon the Influence of the Almond of Spring and Winter filled Trees. ( Phil. Trans. 1800.)
89. Upon the Means of giving Strength to the Stems of Plants propagated from Cuttings. ( lb. 327.)
90. Upon the Culture of the Pine Apple without Bark, or other External Coverings. ( lb. 72.)
91. On the most economical Method of employing Fuel in forcing Houses. ( lb. 140.)
92. Upon the Superficialities of Scions taken from the Trunks of Apple Trees, to those cut from the Extremities of the Branching Part. ( lb. 157.)
93. Observations upon the most advantageous Forms of Garden houses. ( lb. 353.)
94. Upon the Culture of the Guernsey Lily. ( lb. 299.)
95. Upon the Influence of the Almond of Spring and Winter filled Trees. ( Phil. Trans. 1800.)
96. Upon the Means of giving Strength to the Stems of Plants propagated from Cuttings. ( lb. 327.)
97. Upon the Culture of the Pine Apple without Bark, or other External Coverings. ( lb. 72.)
98. On the most economical Method of employing Fuel in forcing Houses. ( lb. 140.)
100. Further Particulars of the Downton Strawberry. ( lb. 192.)
101. Upon the Culture of the Fig Tree in the Store. ( lb. 299.)
102. Upon the Cultivation of the Cockscamb. ( lb. 321.)
103. Observations on Hydras. ( lb. 907.)
104. Observations for preserving Calvards or Fruit Trees in a ve-
getative state, when sent to considerable distances. ( lb. 405.)
105. Observations for preserving Cuttings of Fruit Trees in the Green House. ( lb. 405.)
106. An Account of an improved Method of raising early Potato Plants. ( lb. 405.)
107. On Grafting the Vine. ( lb. 495.)
108. Further Observations on the Culture of the Pine Apple. ( lb. 220.)
110. Description of a Melon and Fine-pit. ( lb. 285.)
111. Observations and disadvantages of curricular hot-houses. ( lb. 257.)
112. A new and improved Method of cultivating the Melon ( lb. 257.)
113. On the flat Peach of China. ( lb. 271.)
114. Observations on the Influence of different peaches on the Moor Park Apricot. ( lb. 287.)
115. Remarks upon some of the Pine Plants. ( lb. 299.)
116. On obtaining early Crops of Peas. ( lb. 405.)
turned to England. He now directed his attention to drawing, architecture, and particularly landscape-gardening; in which last line he obtained considerable success. He died in 1813. He left several sons, one of whom married the daughter of Lord Elton. Repton published some books on miscellaneous subjects; but his principal works are on landscape-gardening.

1. Letter to Vedead Price, Esq. on Landscape-Gardening. 1784.
2. Sketches and Hints on Landscape-Gardening; collected from designs and observations now in the possession of the different proprietors of Seats and Gentleman's houses, which they were originally made; the whole tending to establish fixed principles of laying out ground; 16 colored plates. Lond. 1795. folio.
3. Observations on the Theory and Practice of Landscape-Gardening; containing some Remarks on German and Gothic Architecture, collected from various MSS. In the possession of the holders of Seats and Gentleman's houses, which they were originally made; the whole tending to establish fixed principles in the respective arts: with many plates. Lond. 1803. 4to.
5. On the Introduction of Indian Architecture and Garden- ing. 1809. folio.
6. TwoGE of Ivy upon Trees. (Linn. Trans. 1810, vol. 1, p. 57.)

Hortus Cantabrigiensis; or, A Catalogue of Plants, indigenous or foreign, collected on the grounds of the Botanic garden, Cambridge. Camb. 8vo.

1804. The Cottage Orchard, as described by Frederick Pursh, in 1819, and one subsequently by Lindley.

1805. Lindley, George, nurseryman at Catton, near Norwich.

1. The Plan of an Orchard: exhibiting at one view a select number of plants sufficient for planting an acre and a half of Land, properly arranged according to the time of growth, and hardest of bearing, &c. Lond. 1796, a folio sheet.
2. An Account of some of the best Varieties of Apples peculiarly cultivated in the county of Norfolk. (Hort. Trans. iv. 65.)

Introduction to the Knowledge and Practice of Gardening; with Hints on Fish Ponds. Lond. 1796. 12mo.

1802. Drury, David. A Sketch of the Horticulture of Duck- endfield Hall, near Aston, in Lancashire, member of the Manchester Agricultural Society; now resident on the continent.

1797. Busch, Peter, father to Joseph Busch, gar- deners to the Emperor of Russia.

1798. May, John. A New Method of Driving Earth Worms, and various other Insects hurtful to Fields or Gardens. (Phil. Mag. i. 169.)

1798. Bucknell, Thomas. Ship Dog Beef, Esq. In which is contained a System of cattle Feeding and Medication for establishing the Science of Orcharding, &c. Extracted from the following Transactions of the Board of Agriculture, and from the Manuscripts of the Society's Transactions for the Encouragement of Arts, &c. with additions. Lond. 12mo.

1797. Satisfy, William, nurseryman and botan- ist, botanic garden, Bromley; formerly of Sloane Square.

1. A New Method of Companion; or, a Catalogue of Plants cultivated in the garden of J. Symonds, Esq. Paddington House. Lond. 1795. 8vo.

2. Method of packing Plants and Trees intended for Exportation, so as to preserve the Vegetative Powers for many months. (Oct. 25th, 1795.)

3. The Botanist's Companion, or an Introduction to the Knowledge of the Different Species of Plants, either growing wild in Great Britain, or cultivated for the Purposes of Physic, Medicine, Rural Economy, or the Arts. Lond. 2d. 12mo. 1815.

4. Hints to the Proprietors of Orchards. 1817. 12mo.

5. An Account of the Establishment of a Cottage Gardening, intended to instruct the Industrious Poor in the Rural Arts of raising either growing wild in Great Britain, or cultivated for the Purposes of Physic, Medicine, Rural Economy, or the Arts. Lond. 2d. 12mo. 1816.

6. Hints to the Proprietors of Orchards. 1817. 12mo.

1. impressions of Plants, or Heaths, with Botanical Descriptions. Lond. 1796. folio.
2. The Botanist's Repository, with colored figures of such Plants as are cultivated for the use of Physic, Botany, or Ornamental in Gardens. Lond. 1797-99. 2 vols. 4to.
3. Prints of Plants or Plants hithertofigured in the Botanist's Repository. Lond. 1801. 4to.
4. The Hexthor, or Monograph of the Genus Erica. (Pub- lished in monthly numbers.) Vol. 1 to vol. 4. 1801 to 1812.

1798. Archer, Clarrie, Esq. M.R.I.A.

1798. Nicol, Walter, a Scotch horticultural archi- tect, and author of merit; son of the gardener who planned and executed the gardens and pleasure-grounds of Raith in Fifeshire. After receiving the rudiments of gardening at rural education, in Raith, he went to England, and soon afterwards became head gardener to the Marquis of Townshend, at Rainham Hall, in Suffolk. He afterwards returned to Scotland, becoming head gardener to the Duke of Grafton at West-Berwick, and to the Duke of Gordon at New-Castle. In the year 1810 he undertook an extensive journey through England, for the purpose of visiting the principal seats and plantations, with a view, on his return, to forming a work on horticulture which he felt his work had scarcely commenced, when he was seized with an illness which carried him off suddenly in March 1811.

2. The Practical Planter; or, A Treatise on Forest Planting: comprehending the Culture and Management of Natural and Timber plant; also the Management of Hedges, Fences and the Construction of Stone Walls, &c. Edin. 1799. 8vo.
3. The Viole Gardens; or, A Directory of Monthly Operations to be done in the Town and Villa Gardens, Shrubberies, Par- ticles, &c. Lond. 1799. 8vo.
5. The Gardener's Kalendar, for the year 1810, and a New Forester's Guide to the operations of the Nursery, the Foret, and the Garden, compiled by Samuel T. S. Robinson. Lond. 1810. 8vo.

1798. Robinson, J., a London architect, nephew to Thomas Robinson, Esq. gardener to Geo. III. at Kew. Forms of Stoves used for Forcing-houses. Lond. oblong 4to.

1800. Hill, Daniel, M.D. F.R.H.S.
1. Practical Observations on the Use of Oxygen, or Vital Air, in the Cure of Diseases; to which are added a few Experi- ments on Plants and Animals. Lond. i800. 4to.

1800. Pontey, William, planter and forest pruner to the Duke of Bedford, and ornamental gardener; resident at Buckland, where his brother is a respectable nurseryman.

1. The Profitable Planter; A Treatise on the Cultivation of the Larch and Beech Trees, with directions for raising his own, and afforesting every green space, &c. Lond. 1794. 1st edition.
2. Forrest Planter, or Timer Owner's Assistant; being a Treatise on the Pruning or Management of British Timber Trees, whether intended for use, ornament, or shelter; including an explanation of the causes of his general defects, with means of prevention, and remedies, where practicable; also, an examination of the properties of English Fir Timber; with the effects of an afforestation of British woods, and the lines of a new system for the management of Oak Woods. With eight plates, a folding plan. Lond. 1803. 8vo.
3. The rural improver, &c. Huddersfield, 1825. 4to.

1802. Society of Practical Gardeners; evidently, however, a society managed by a hackney writer who knew little of the subject.

Rural Recreations, or the Gardener's Instructor; exhibiting in a clear succinct manner the different operations necessary in the Kitchen, Flower, and Fruit Gardens, &c. for every month in the Year; with a Treatise on the Management of Bees, &c. and title-page in foreign characters.

1803. Loudon, John Claudius, landscape-gardener, and author of some works on agriculture; born in Lanarkshire, in 1783, began on his premises to farm extensively in Oxfordshire in 1800, and in Middlesex in 1810; travelling on the continent in 1813-14-15, again in 1819, now residing at Bays- water.

1. Observations on laying out the public Squares of London. (Diary Journal, 1802.)
2. Observations on the Formation and Management of Useful and Ornamental Plantations; on the Theory and Practice of Cutting and Motting, and on the numerous Embankments and Embankment Land from Rivers, or the Sea. Edin. 1804. 8vo.
4. A Treatise on forcing, improving, and managing Country Recreations: with a view to the choice of the most proper and different kind of Comestibles proper for every class of Purchasers. With an Appendix, containing an Exposition of the Scientific and Artistic Principles of the Theory and Mode of showing Effects by Slides and Sketches, and Stric- tures on his plan of Country Recreation in Landscape Gardening, illustrated by Descriptions of Scenery and Buildings, by references to Country Seats, and passages of Country in most parts of Great Britain, and in foreign countries. Lond. 1805. 12mo. 4 vols.
6. Remarks on the Construction of Hot-houses: pointing out the most advantageous Forms, Materials, and Contrivances to be used in their Construction; with a Review of the various Methods of heating in hot-houses, and the supposed advantages of them in England; with 16 plates, from engravings on stone. 1817. 4to.
7. Sketches of Curtain Hot-houses; with a Description
BRITISH WORKS ON GARDENING.

1.8. A comparative View of the common and curriuline Malus of the English and France. (Hort. Trans. 1. 268.)

10. The different modes of cultivating the Pine Apple from its first discovery to the present time. By Mr. James Daglish, Esq. R. S. O. Lond. Svo. 1825.

11. A treatise on the propagation of Orchids, and of the tuberous Lathyrus, with Instructions for the Cultivation of the Plant in a Garden. (Hort. Trans. iv. 359. 1817.)

12. On the mode of cultivation of the Fennel. (Bot. Mag. t. 19. 1818.)

13. Macdonald, Alexander, a fictitiously name adopted by R. W. Dickson, M. D. formerly of Hen- don, Middlesex, author of Practical Agriculture, and other works on farming. Svo. 1815. 10s. 6d.

15. The plates of flowers from paintings by the late Syden- ham Edwards. 1817.

17. Crying out for India: I was published with Soane's Designs for Villas. Architectural Sketches, 4to. 1817. No. 1. These contains plans for laying out grounds, according to the different natural situations; with descriptions: among others: a plan of Gen. Washington's grounds at Mount Vernon.

19. Ellis, Daniel, Esq. of Edinburgh. An Inquiry into the changes induced on Atmospheric Air by the General Deposition of Plants. Edin. 1807. 5vo. 10s. 6d.

20. Further An inquiry into the changes induced on Atmospheric Air by the Germination of Seeds, the Vegetation of Plants, and the Respiration of Animals. Edinb. 1811. 8vo.

23. On the Management of Grapes in Viviers. (Hort. Trans. i. 96.)

25. Improved Methods of Cultivating the Plants belonging to the Order of the Protea. Generally attributed to R. Ilkley. Lond. 1819. 8vo.

26. On the Cultivation of Horse-Radish. (Hort. Trans. i. 307. 1819.)

27. Aiton, William Townsend, Esq., gardener to the King's Garden at Kensington. To the first situation he succeeded on the death of his father, William Aiton, in 1793, and to the other on the death of Mr. Forsyth, Esq., in 1806.

29. An Epitome of the 2d. edit. of Hortus Kewensis, for the Use of Practitioners in Greenhouses; to which is added, a Selection of Raisons, Vegetables and Fruits cultivated in the Royal Garden at Kew. Lond. 1814. 8vo.

30. A Brief Practical Description of the Cultivation of the Cucumber in the Royal Gardens at Kew, during the Autumn and Winter of the year 1814. Lond. 8vo.

31. Dean, R. and W. printers, Manchester. An Account of the different Gooseberry Shears used in Lancashire. 1815. 12mo. To be added, a Statement exhibiting at one view the number of Prions won, by each sort of berry at the several Meetings, Manchester. 12mo. annually continued.

33. The Caledonian Horticultural Society. Founded in 1820, chiefly through the exertions of Dr. Anderson, of Prann, a native of the Institute of Medicine in the University of Edinburgh. It is a prosperous, well conducted, and most useful society. Memoirs of the Caledonian Horticultural Society. Edin 3 vols. Svo. to 1824.

34. In the Mode of forcing the vine in Denmark. Lond. Svo. 1821.

36. An account of the methods of forcing peaches in Denmark and Holland. (Hort. Trans. v. 506.)

39. Interesting Discoveries in Horticulture; being an easy, rational and correct method of planting all hardy American and Bog Soil Plants, with Ornamental Trees and Shrubs of general Description, Green-house Plants, including Botany of the icicle Plant, or Jasmine, and the poisonous and poisonous Fruits, the favorite Shears and Fruit-trees in every variety, by planting Cultivating and handling them within the walls of hot-houses. Lond. 1811. roy. Svo.

41. Thomas, nurseryman, at Northamptonshire. On collecting Seeds and improvements and preparing them for nursery work. Lond. 1812. 8vo.

42. Hooker, William, Esq. F. L. S. H. S., horti- cultural draughtsman and engraver. From many orders for press representations of the best Fruits cultivated in British Gardens; with Descriptions. 1815. 4to. To be completed in about 18 numbers.
1811. Wade, Walter, M.D., Professor of Botany to the Dublin Institution.

1812. Cushion, a native of Ireland, late foreman to Mr. James Lumby, a nurseryman, at Faddington, Leicestershire, and late at Kennett, at the Hammersmith nursery.

1813. Hoggs, Thomas, master of an academy at Palace, Middlesex, and a very successful grower of the carnation.
1. A concise and practical Treatise on the Growth and Culture of Carnations, Fuchsia, Polyanthus, Ranunculus, Tulips, &c. Lond. 12mo. 1 plate.
2. Todd, George, surveyor and hot-house builder, employed by W. T. Atton, Esq., the late Sir Joseph Banks, and other eminent landowners. Fadington, 1813.
3. Sinclair &c, Sir John, Bart. of Ulster, in Caithness, a distinguished patriot and voluminous agricultural writer; founder of the Board of Agriculture.

Account of some experiments to promote the improvement of the climate of Fadington, by planting trees. These experiments were made by F. Lyon, of Edinburgh. (See Lyon, 1816.)

1815. Pitcher, Mr. Edward, late gardener to Viscount Kirkwall, in Wales, patentee of a forcing-frame (1823.); and now hot-house builder at the Horticultural Repository, King's Road, London.

1. A Treatise on forcing with useful hints on forcing, by a new device for the application of Frames to the Cultivation of Fuchsias, and other greenhouse plants; and of the Early Esculentus usually in demand for the first tables; including a few plain Directions for forcing the Grape, Cherry, and Peach in Houses, with a concise description of the Patent Framing Force, and exhibiting some of its advantages, in respect to sheltering the plants, connecting the principal parts of the theory of vegetation, with the practice of Horticulture. Edinburgh. 1815.

1816. The London Horticultural Society, commenced by a few individuals in 1804, and established by charter in 1806. It is perhaps one of the most flourishing and best conducted societies of the kind in existence.

Transactions of the London Horticultural Society. Lond. 1805. 8vo.
1. Ato, many plates, 1824. 12mo.

1816. Sæder, J., nurseryman, seedsmen, and florist, Wells Road Nursery, Bath.

1. An advertisement, "humbly requests that those who purchase his book will not give the rules therein laid down to others, as it will materially injure the sale thereof."

1818. Brookshaw, George, a teacher of flower-planting.

1. Pomona Britannica, or a Collection of the most established Covent Garden Florists, at the Royal George, in women's gardens at Hampton Court, and from the most celebrated garden round London, accurately drawn, and colored from nature. 12mo.

2. The Horticultural Repository, containing Delineations of the principal species of English Fruits and Flowers; to which are added the blossoms and leaves, in those instances in which they are considered necessary, accompanied with full descriptions of the varieties, and directions for planting them, so as to insure a longer succession of fruit and bloom. London. 1819.

1819. Baldwin, Thomas, gardener to the Marquis of Hertford, at Hertford Green, in Warwickshire.

1820. Forsyth, steward to T. W. Cake, Esq., of Holkham, in Norfolk, some of the most celebrated fruit-growers in the garden of the Earl of Mount Edme, in Lincolnshire, and from the cultivated plants, &c.

1821. Hayward, Mr. Joseph, gent., an amateur gardener, formerly a Yorkshire clothier, now residing at Plumstead in Kent.

2. Mr. Robert, a native of Aberdeen, and surveyor in London.

3. An Essay on the Origin and Operation of the Dry Root; to which are added some Remarks on the Culture of the Dry Root, and an Abstract of the Forest Laws. Lond. 1819.

4. Post, Mr. William Bridgeswick, C.M.H.S., nurseryman, Southampton, and a member of the law of Kennedy, late of the Hammersmith nursery, who is the reputed author of Page's catalogue.

1822. Fergusson, as a general name for all the plants, indigenous and exotic, cultivated in the Southampton botanic garden, and belonging to the indigenous and exotic departments, are considered or tender or hardy to the climate of Britain, under their different characters of trees and shrubs, herbsaceous, &c. The generic and species names of the Linnaean System are given in English language, propagation, soil, height, time of flowering, native countries, and general hints for their cultivation. An Appendix, containing selected lists of annuals; all the choicest kinds of flowers now in circulation, with their characters, &c., and a description of the various societies, from the Linnean phytology of Linneus. London. 8vo.

1823. Knapton, Mr. Richard, a nurseryman, viscount at Seling, a有益于pesticides, which he was for destroying all manner of insects.

1824. Hoole, Nathaniel John, F.L.S., an able practical botanist.

1825. Field, Henry, member of the Society of Apothecaries, London.

Memoirs Historical and Illustrative of the Botanic Garden at Chelsea; belonging to the Society of Apothecaries of London. Lond. 8vo. 1825.

1829. Holfand, Mrs., formerly Mrs. Hoole, now the wife of a eminent landscape-painter, author of various novels and some poetry.

An Historical Description of White Knights, a seat of the Duke of Montagu, near Reading. Lond. Imp. fol.

1. The Literary papers by Mrs. H., and the engravings by her husband.

1830. Hope, Thomas, Esq., of Deepden, near Godstone, in Surrey, a gentleman of highly cultivated taste, author of a splendid work on household furniture, and of Anastasia, a novel displaying much genius.

An Essay on Gardening, published in the Description of White Knights, by Mrs. Holfand. 1830.

1. Hope, Mr. Henry, formerly master of an academy at Bayswater.

1. Fomarian Britannicum, an Historical and Botanical Account of Fruits in Britain. 1830.

3. Sylva Florisera; or, the shrubbery. London. 2 vols. 1832.

4. Folia Dendronica. 1 vol. 8vo.

1. Some rare plants, cultivated at Bayswater.

1833. Cobbe, William, a well known political writer, son of a farmer, born at or near Farnham, in Surrey, in 1776; in 1803 he went to London, and was employed in the office of the attorney-general. After being attac- kered into a regiment sent to America, went to France in 1792, returned the same year to America, and was engaged in literary pursuits, and returned to England, in 1801, went to America again in 1816 (?), and returned in 1820, and now resides in Kenning- ton, where he has a large garden.

1. The Amelioration; or, a Plea for the Preservation of the Soil, Fencing, and Laying out of gardens, on the Making and Maintaining of common roads, and on the Establishment and Cultivation of the several parts of Vegetables, Herbs, Fruits, and Flowers. London. 12mo.

1836. Though the natural sciences are more vigorous than botany and phytology, he has contrived by his style, by many shrewd remarks, and by curious and ingenious applications, sometimes at variance with facts, to make an interesting book, from which it may be gathered, that horticulture is an American science from which we may have great obstacles to contend with.

1. Neil, Patrick, Esq. A.M. E.L.S., secretary to the Natural History Society of Edinburgh, and to the Caledonian Horticultural Society, author of a
tour through the Orkney and Shetland islands, published in 1806; and of various essays and papers on natural history in the ScotchEncyclopaedia: a most eminent and intelligent man, and a skilful horticultural connoisseur.

1. Notice of Mr. Knight's Doctrines regarding Fruit Trees. (Ed. Memo. iii. 215.)

**Sect. II. Of the Literature of Gardening in Foreign Countries.**

7691. Italy having been the country in which the revival of arts and literature took place, was the first to produce books on agriculture and gardening: that of Crescenzi is well known. The adjoining countries of France and Germany produced the next books; and those of Belon, Ettienne, and Hesperbius, may be cited as among the best of the 16th century. Commelin is among the earliest Dutch authors on gardening; Rudbeck, his contemporary, one of the first who wrote in Sweden: both published after the middle of the 17th century. Herrera, one of the few Spanish writers on agricultural subjects, wrote about the end of the 16th century. The other countries of Continental Europe have produced little worthy of notice; and but few gardening books have hitherto appeared in America. Of such as are most generally known in this country, or apparently most interesting as illustrating the state of gardening at the time of their production, we give the titles in the following subsections.

**Subsect. I. Works on Gardening published in France, exclusive of Translations.**

7692. Of French works on gardening we have given a more copious list than of those of Germany, because the French language is more generally known, and the books not difficult to obtain. Many of them are in the libraries of the British Museum, the Horticultural Society, or in the Banksian collection. One of the best books on the state of culture in France is, the Nouveau Cours d'Agriculture, 13 vols. 8vo. 1810.

1533. Champlain, Synophrum, a physician, a native of Lyons, who distinguished himself in the battle of Agincourt, 1419, and was made chevalier of the two gilt spurs; he wrote several works, and died in 1539 or 1540.

Campos Elias Gallus amanuensis refertus, in quo quidquid apud Indos, Arabos et Paras repertum, apud Gallos demonstratur posse reperiri. Lugdun. 8vo.

1536. Arbusinum, a physician of Paris, who wrote several tracts on gardening and agriculture, and first united them in one work in 1529, under the title of Prudium Rusticum. Having married his daughter to Jean Leibault, also a physician, he produced, with his son-in-law, the Maison Rustique in 1570.

1539. Belon, Peter, a French physician, was born in the province of Maine, and was advanced in his profession, where he was shut up on account of his religious opinions.

De Hortorum familiae. Basili, 1546.

1542. Arbusinum, D'Arbois, Daniel, a Benedictine monk at Mons, belonging to a family which still exists in the Maine.

1543. Belon, Peter, a French physician, was born in the province of Maine about the year 1518. He travelled into Palestine, Greece, and Arabia, and published an account of the plants of those countries in 1555, 4to. He was at Paris in 1564.

1547. Latour, Corsus, Georges, or Gorgole de Corse, according to some writers a native of Florence.

1. Maniere d'Enter, Planter, et Nourrir les Arbes et Jardins, avec les moyennes des autres traitez d'Agriculture. 8vo.

2. De la Maniere de Planter, Arracher, Labourer, Semeur et

Sommer les Arbres Sauvages, Bois Haut et Bois Taillis.

Paris, 8vo.

1563. Davy, P——, that is, Perc David, or David Brossard. (See Brossard, 1552.)

1563. Puisaye, Bernard de, born at Agen in 1524, was a physician, according to purchasers, or literary manufacturer, according to others. He cultivated chemistry and the arts, and went beyond his age; he wrote many pieces, which have been collected published in several volumes. Those which relate to agriculture and rural economy, are entitled, Moyen de devenir riche. He died between 1602 and 1614.

Receive veritable by laquelle tous les hommes de la France pourront apprendre a augmenter leurs Travaux, le Journal d'un Jardin délectable et utile. Rochelle. 4to. 1563.

1564. Mizauld, ———, born at Montjuich, in 1576; died at Paris in an advanced age. He studied mathematics and medicine with reputation; but his love of novelty, singularity, and astrology, made him lose in succession the little glory which he had acquired, his fortune, and his life. He wrote many works, chiefly in Latin, the first of which, on gardening, appeared in 1564; and all those which relate to the subject have been collected and published by Callie, a physician, in the following title:

1570. Lebois, Jean, a physician, born at Dijon, died at Paris in 1596; author of various works on medicine, and jointly with his father-in-law, Etienne, of the Journal rustique. (See Etienne, 1553.)

1580. L. D. ———, Avertissement et maniere d'enter assurément les Arbres en toutes saisons, pour les faire croisir. Bourgogne.

1586. J. P. D. M., that is, Jacques Pons, Doctor of Medicine.

Sommaire contenant des Melons. Lyon de Tournes, 8vo.

1611. Garnier, Claude.

La maniere d'enter, planter, et semer, avec les remèdes contre les moncherons, fées-maures, et autres bêtes qui gîtent les arbres et jardins. Troyes. 1610.

1615. Bourgu, Jaccques, écuyer; sieur de la Baruade, intendant of the garden of Louis XIII.

2. Traité du Jardinage qui enseigne les Ouvrages qu'il faut faire pour avoir un Jardin dans sa perfection, et la maniere de faire des plantes et arbres ether, plusieurs times requiert.

1631. Mollot, André, a relation and contemporary of Claude Mollot, who was gardener to Henry IV., and bears the title of Frankifi, of France, as the other is said to have been to James I. of England.

1. Le Jardin de Plaisir, containing several Descriptions of Jar-
1652. Mollet, Claude, head gardener to Henry IV., and of Louis XIV.; he created in France, in 1682, the parterres à compartiments; in 1693, he planted the garden of Saint Germain-en-Laye, of Monceau, and of Fontainbleau; in 1697, he had planted at Fontainbleau 7000 fruit-trees; he had, in 1686, made fiûts of cypress, and of the Thuileries, which were killed by the rigorous winter of 1686. On the whole, he effected a great deal for the time in which he lived, and his name and memory are often too much forgotten. Andrew Mollet, was gardener to James I. in England. (See Mollet, André.)

1658. Morin, Pierre, a florist at Paris, mentioned by Evelyn; he devoted 40 years of his life to the culture of flowers, and was, the French authors say, the cleverest of his time.

2. Observationes circa Culturam Plantarum. 1660. Saint Etienne, Claude le, a Bernardin monk.

2. Several editions, with the title somewhat varied, as Nouveau Traité pour connaître, &c. 1677. 

1664. Nepveu, a Jesuit, was born at Tours in 1612. He taught polite literature with great reputation in the colleges of his order; and died at Paris in 1685.

2. Nemus; translated into English verse by Evelyn junior. Evelyn, in his Travels, and in his Greek and Latin Poems, translated by him were published separately, 1673. 8vo. Lond.

1. This author believes in the influence of the moon, and couples many curious superstitions practices to secure successful culture.

1. Aristote, jardinier de Puteaux, considered him as one of the French bibliographers as an assumed name, and designation.

1. This work was published through many great editions in France, and was translated by Evelyn in 1653, under the title of the French Gardener.

1686. Dahuron, René, gardener to the Duke of Brunswick, at Lunenburg.

1688. Dauthin, Jean de la, born in 1625, at Chabanois, near Angouleme, died in 1700. He was destined for the bar, but a passion for gardening determined him to that pursuit. He became tutor to a young master, T. Tamberanno, and accompanied him on the tour of Italy with him, where his passion for his favorite study increased. At his return, the father of his pupil submitted his gardens to his direction. Here he gained experience and reputation. The great Condé used to take pleasure in conversing with him, and Charles II. of England invited him to superintend his gardens, with a considerable pension.

1. Traité des Jardins Fruitiers et Potagers. Amsterdam. 4to. fig.

2. Instruction sur les Jardins Fruitiers et Potagers, with a Traité des Oranges, and des Réflexions sur l'Agriculture. 4to. Both were revised, each in French, and were translated into English by Evelyn, and by London and Wink.

17. Lemaire, Fr. — Supplément aux Mêmes des Jardins d'Usul et d'Ornement; contenant des nations sur la culture de diverses plantes; entre autres du rutabaga au chou-mauro de Lapone, qui ne gèle jamais en terre, et qui remplace le colza; sur de nouveaux arbres et arbustes, tels qu'un nouveau Rosier, le Mignonot, et autres; ainsi que les fruits, les baies, les myrtilles vivaces en pleine terre, et l'autre des arbres et arbustes. Paris. 12mo.

17. Petel, M. de St. Maurice, member of the Paris Agricultural Society.

1. Memoire sur la Culture des Pommiers dans toute l'Industrie de la France. Rouen, 8vo.

1701. Marchant, — of the Academy of Sciences. Dissertations which he has published in the Jardins de Planetes of our Pays, par-dessus les Plantes étranferees.

1703. Liver, Louis, born in 1658, died in 1711; author of various works on rural and domestic economy, and of a Théâtre d'Agriculture, in several volumes, and a new edition of the Maison Rustique.

1. Traité facile pour apprendre à éléver les Figuiers. 12mo.

3. La Culture parfaite des Jardins, Fruitiers, et Potagers. 12mo.

1704. Tanchier, — a physician in Paris, father-in-law to the celebrated physician Dionis.

1705. Franceois, one of the brothers of the Chartreux in Paris.

1. Le Jardinier silicatif, ou Dialogues, concernant la méthode de cultiver les Arbres et Jardins, &c. An edition in 1705, with the title somewhat varied.

1705. Lapéde, a naturalist and anti-quarian, author of several works.

2. The same work in English, 8vo. 1784.

1707. Tournefort, Joseph Piton de, a physician and botanist, was born at Aix, in Provence, June 5, 1656. He was intended for the church, but on the death of his father he relinquished the study of
FRENCH WORKS ON GARDENING.

1712. Boulay, —, canal of Orleans.

1716. Jesseon, Jean-Baptiste Deschesins de, born at Chalons; died in 1736. He was lieutenant-gener- al of the army, and a member of the Society of Sciences; united a taste for arms with that for study, and excelled in both.

1722. Sauvage, the Sieur de, gardener to the Princess of Condé, at Anet, afterwards inspector of the gardens of the Duke of Orleans.

1730. Hamel du Monceau, Henry Louis de, a distinguished naturalist, was born at Paris in 1700. He became a member of the Academy of Sciences, to whom he communicated a number of papers on various subjects of physiology. He died at Paris, where he was dean of the academy, in 1782.

1. De l'importance de l'Analogy, et des Rapports que les Sens ont pour la Musique, et la Duree des Griefs. (Mém. Acad. Par. 1730. 31.)

2. Traité des Plants qu'on peut éléver dans l'Eau. (Mém. Acad. Par.)

3. Traité des Arbres et Arbustes, qui se cultivent en France, en Bretagne, &c. 4to.

4. Physique des Arbres, où l'on traite de l'Anatomie des Fruits, de la Nourriture, &c. 12mo. 1735. It is published under the title: Le Livre sur l'Utile des Matières de Botanique, et une Explication des Phénomènes des Arbres Plantes, avec des Planches gravées de Coques, &c. Avec un Discours sur les griffes des arbres. It is a very important work, and on it his merit as a Physiologist chiefly rests.

5. Traité complet des Bois et des Forêts. Par. 1736-67. 6to. 4mo.

6. Arbres et Plantations des Arbres, et de leurs Cultures. Par. 1769. 4to.

9. Bois, 4to. 1767. 4to.

10. Des Arbres Fruitiers. Paris, 1768, 2 vols. 4to. With fine coloured plates of fruit-trees, &c. This is his most important work.

11. Guérin, M.

12. Traité de la culture parfaite de l'Oreille d'or. 12mo.

13. Cahier de l' Observateur, born at Lyons in 1769; practised physiology, and became curator of the plants in the royal garden of Paris, and superintendent of that at Triana. He is the first gardener in this last garden to cultivate a system which bears the family name, and has been so much perfected by his nephew, Antoine de Jussieu. All the members of this family have been devoted these years to the cultivation of plants.

15. Thiari, André, the Chevalier, Professor of Culture in the University of Paris; author of various memoirs on gardening and agriculture, inserted in the French Encyclopédia, dictionnaires and periodical works, and in the transactions of their learned bodies: an excellent man, and esteemed one of the first gardeners in Europe.

1. Mémoire sur l'usage de deux fleurs dans la Culture des Arbres et Arbustes étranges, regardées jusqu'alors comme dégénérées. (Mém. de la Soc. R. d'Agricult. de Paris, t. 2. 1749. 11.)

2. Sur les Avantages de la Culture des Arbres, étrangers pour l'essor et la fioriture de la nature abondement connu comme stériles. (Mém. de la Soc. R. d'Agricult. de Paris, t. 2. 1749. 11.)

4. Description de l'Ecole d'Agriculture pratique du Musée d'Histoire Naturelle, tel qu'elle se fait dans le tomo. 10. 1761.)

5. Mémoire sur les nouvelles Mots de griffes. (ibid. tom. 11.)

6. Notes sur la Culture des Patates et des Pommes de terre. 8vo. de la Plante. (ibid. tom. 3. p. 185.)

7. Mémoire sur la Culture des Bruyères. (ibid. tom. 11.)

8. Mémoire sur la Culture des Dahlia, &c (ibid. tom. 5.)

9. Monographie de griffes, ou Description technique de diverses griffes, pour servir à la culture des arbres et des arbustes; avec ses Tables. (ibid. tom. 9.)

1739. Buffon, George Louis le Clerc, Count de, was the son of a councillor of the parliament of Dijon, and born at Montbard, in Burgundy, in 1707. He studied at Dijon, and was intended for the law, but his inclination lay to the sciences, particularly that subject which was afterwards to make him no longer without Euclid's Elements in his pocket. At the age of twenty he made the tour of Italy, and afterwards visited England. On his return home he divided his time between Montbard and Paris, and in 1755 published a translation of Halle's "Vegetable System," which was followed by one of Newton's "Philosophical Transactions." In 1759 he purchased a house as an attendant of the royal garden and cabinet, by which his care was considerably enriched. He was a member of the French Academy, treasurer of the Society of Sciences, and in 1771 he was created a count. His private character was that of a libertin, and he was extremely vain of his person and talents. "The veritable genius of eminent geniuses," he would say, "are few; they are those of Newton, Bacon, Leibnitz, Montesquieu, and my own!" He died of the stone in his throat, and only a single grain of sand was left in all his works. 4to.

1. Mémoire sur la Conservation et le Rétablissement des Forêts. (Mém. Acad. Par.)

2. Note sur la Culture des Fruits. (ib. ib.)

1741. Binenz, Gilles-Augustin, a physician of Strasbourg; author of some tracts on insects, trees, &c. died in 1754.

1. Observations sur les Plantes, et leur analogie avec les Insectes. 8vo.

2. Traite de l' Arbrisseau des Plantes. 8vo.

1745. De Comité, a native of Lyons, began to write on agriculture in 1745, and after a long life of agitation, he retired to a country-house near Paris, where he gave himself up to gardening.

1. Traité des Erables; 8vo.

2. L'Ecole de l'Ejard Potager. 2 vols. 12mo.

1759. Labouret, a native of Lyons, was an arboriculturist, and in 1759 published the fifth edition of L'Ecole du Jardin Potager. 8vo.

1765. Franchère, Joseph Dufresne de, of the academy of Berlin, born at Doutrets in Picardy.
in 1704; better known by the first edition of Voltaire's "Siècle de Louis XIV," which appeared under his name, than by any of his other works.

Catiline ou les Vénètes de la France, 12mo. 1757.

Marè, M.- Pierre, Traité de la Culture des Renoncles, Eillettes, Auricules, et Tufes, 1765.

Bertrand, Francis, a citizen of Paris, enthusiastically attached to the country, but not being able to live by his writings, he has earned his bread by collecting passages from the poets on the pleasures of a country life. Roi de délice. Collectes ex melioribus notis Latinis Gallicisque Poëta. Paris, 1760.

Barbeville, M.- born a Svo. of the celebrated Château de la Cheronnière, born in Beaune, author of some tracts on political economy and agriculture. Traité de la Culture de divers féculents, Nardes, Girouilles, Tubéroses, Aménones, Jacinthum, Jorquilles, Iris, Lits, et Amanitas, 1764.

Barbeville, M.- the celebrated Château de la Cheronnière, born in Beaune, author of some tracts on political economy and agriculture. Traité de la Culture de divers féculents, Nardes, Girouilles, Tubéroses, Aménones, Jacinthum, Jorquilles, Iris, Lits, et Amanitas, 1764.

Barbeville, M.- the celebrated Château de la Cheronnière, born in Beaune, author of some tracts on political economy and agriculture. Traité de la Culture de divers féculents, Nardes, Girouilles, Tubéroses, Aménones, Jacinthum, Jorquilles, Iris, Lits, et Amanitas, 1764.

to the text, and a description of Stow, where he is said to have resided some time with Lord Temple.

1775. Pelletier, de Freiption, — Essai sur la taille des Arbres Fruitiers. 12mo.
1777. Watlet, Claude Henri, receiver-general of finances, member of the Academy of Sciences, and other learned bodies, with the approbation of the Academy. He was celebrated for his love of arts and letters, and enjoyed himself at his country-house, called the Maley. He married near Paris in the English garden, and wrote on the subject. He died in 1785.
1778. M. Robert Xavier, author of several works on agriculture.
1775. Roubo, — jointer and architect, author of several works on joinery, died about the end of the Eighteenth Century.
2. Durival, Clement, brother of N. L. Durival, an agricultural writer, was born at St. Aubin, in 1728; he wrote on the finances and rural economy, and in the year 1780, a piece on wine was crowned with the prize at Metz, in 1771.
3. La Vigne, Memoire Couronn, a l'Academie de Metz, par le Journaux Le Jeune. 8vo.
1777. Girardin, L.R. Vicoitpe de Ermenonville, a military officer of high rank, who travelled in England and France; in the time when the new style of laying out ground was coming into fashion; and when he returned to France, laid out his seat at Ermenonville in this style.
1. La composition des Paysages sur le terrain, ou des moyens d'ameliorer la Nature autour des habitations, en y joignant l'Art du Jardinage. This work has been translated into English, with an historical introduction by Daniel Mathews, Esq.; and also into German and Italian.

Another edition, with notes, was published a few years ago, by Dr. G. D. Dufrenoy, the French translator of Dufrenoy. This is recommended for the amusement of all who are interested in the art of gardening.
1780. Lamolignon, Matheus, Christien-Guillaume, born in Paris in 1751, and cultivated there the rare species of exotic plants in fantastic gardens, shown by an excellent man, attached to the arts, and introduced on his estates many exotic trees.
Observations sur les Arbres, le Melon, &c. 8vo.
1780. Marichal, Pierre Sylvain, born at Paris, in 1750, died in 1803; author of a great many works, the principal of which is a Dictionary of Alchemists. This dictionary was translated into English, French, and Italian. 8vo.
1781. Henriquez, Jean, a lawyer, author of different works on forests and the chase.
Observations sur la Maniere de multiplier les plantations de bois sans naire a la Production des subsistances. 8vo.
1782. Parmentier, Antoine-Augustin, born in 1739, a celebrated botanist, in the department of La Sierra, one of the most distinguished chemists, and active and careful philosophers which has appeared in France. Author of a great number of works, and especially the following:—in the Archives de Chimie, Nouveau Cours d'Agriculture, &c.
1. Recherches sur les Vegetaux nourritoor qui, dans le temps de desseve, peuvent remplacer les aliments ordinaires; avec des nouvelles Observations sur la Culture des Plantes de Terre. Paris. 8vo.
1782. Barruel-Beauvert, captain of dragoons under the old regime.
1. Plante du Chou et du Navet contre les Jardins de l'Abbe Lille, S. In verse and considered a pleasant article agreeable, picturesque and fondant.
1782. Porcin de la Roche-Tulles, doctor of laws, canon of Monteuille-Bellay, in Anjou; born in 1748 at Dissais. The portrait Vigenor, on the Art of Cultivating the Vines, to faire le Vin de Bourgogne. Amsterdam, 1772.
2. Ecole du Jardinier Fruitier. 2 vols. 12mo.
1783. Conard, Abraham, potager. 4 to.
1783. Durand, — a physician of Dijon, where he died in 1749, author of several works on botany.
1785. Watrel, — Traitie Theorique et Pratique de la Vegetation, contenant plusieurs Exemples de vegetabilzation par nouvelles Oeuvres des Jardins, &c. (Mem. de l'Acad. de Dijon. 4 vols. fol.)
1785. Secondat de Montesquieu, son of the celebrated author of Esprit des Lois, died in 1766, aged 79, and never moved by the prospect of which his father had rendered illustrious; and had so great a respect for his memory, that he preserved in the Chateau of Brde the furniture and the exact order in which his father had left them. He occupied himself chiefly in the study of natural history, and in agriculture.
MEMOIRE SOBRE LA NATURE SAINTE DU CHAMP, sur la rist dispensation des Bois a etre rompu par les pots dont ils sont charges sur la commission de l'Assem. Nat. fol.
1786. Calanis de Sallongue, born at Bordeaux in 1722; died in 1786; advocate of parliament, member of the Agricultural Society of Limoges.
1787. Lézage-de-Marnesia, — born at Besan- pon, and Paris in 1724, aged 60 years; a member of the assembly, &c.
A very rare work, which has passed through several editions.
1789. Bousnard, — a Frenchman, a captain in the Russian service, supposed to have been slain in the siege of Eupatoria.
1788. Fontaines, Louis de, Grand Master of the University of Paris, and President of the legislative body, &c.
Le Verger, poeme. 8vo.
1789. — 2. Memoire sur les plantations des arbres fruitiers, sans trop naire a la Production des subsistances. 8vo.
1790. Barruel-Beauvert, formerly president of the parliament of Metz.
Supplément au Dictionnaire des Jardiniers, qui comprend tous ces travaux qui ne sont pas encore publiés, ou qui sont moins détaillés dans le Dictionnaire de Millier. Metz. 8vo.
1790. Masson-de-Bironmont, Charles-Francois Philip- bert, born at Blamont in Montbelliard in 1765; became a colonel in the Russian army, and exiled from his country in 1797; in 1802 became secretary of the prefecture of Coblenz, and associate of the institute.
Voyage au Mazar’s English Garden, and Wheatley’s Observations, into French.
Les Jardin de Sambour, paroisse Roue, traduit du Russe en Frangais. 8vo.
1790. Hervé, M. Villé, directeur of the Royal Gar-
den of the Luxembourg. Mr. Hervé's father was
gardener to the Chartreuse monastery, where fruit
trees and plants were propagated and for-
wards of half a century before the revolution.
In the early part of this revolution, the elder Hervé,
foreseeing that the establishment would be put
down, and collected for and obtained from the
existing government to establish a national
garden of fruit-trees, and the garden of the Lux-
embourg was made the receptacle of this collection.

1801. Dussieux, a new edition, with a supplement, on the Greffe, in 1802.

Catalogue Méthodique et Classique, de tous les arbres,
arbusiers, et arbustes que l'on voit à l'école imperiale et des
arbres et buissons en France, 1800.

1798. Carlton, arboriculturist, and architect-engineer
at Grenoble.

1. Le Général des Cultivateurs. Grenoble. 5vo.
2. Camp-d'oil Politique et Economique, that actuel des
Bois et Forêts en France, suivi d'un projet d'Institution For-
êtrière. Grenoble. 5vo. 1801.

Principes raisonnés et Pratiques de la Culture des Arbres Fructueux, Plantes Médicinales, Arbustes domestiques,
d'agrement, des graines, plantes potagères et legumeneuses,

18. Larochefoucauld-Liancourt, a proprietor of
considerable extent, who studied agriculture under
Arthur Young, and travelled in North America.
He has published his travels, and some other works,
but is best known in France by the vastes entreprises
which he made on his estates.

Notes sur le Chêne. Par. 8vo.

1800. Berthollet, native of Lyons, where he died in
1792. He was professor of physical science at
Montpellier, and afterwards of history at Lyons;
the friend of Franklin, and author of several works on
rural, political, and domestic economy.

17. Mémére su la famille de crucifères. Geneve. 8vo.

SUBJECT. 2. Works on Gardening published in Germany, including Denmark and Switzerland, exclusive of Translations.

7693. The Germans have an immense number of books on every subject, and in the gardening department are more especially prolific on the subject of planting and forests. We have made a selection, with a view to giving an idea of the progress of gardening in Germany, and also to include the books contained in the Banksian and other public libraries of this country. Every English work of merit is translated into German as soon as it appears, and the same may be said of the best works of France, and of every other country.

Two of the most desirable books for giving an idea of the state of culture in Germany, are Dietrich’s Wörterbuch, with the Supplement to 1820, 10 vols. 8vo.; and Sickler’s Deutsche Handwörterbuch, many vols. 8vo.

849. Anon., ascribed to the learned Benedictine, Wallafrid Straban, of the diocese of Constance, who died in 849.

Hortulus. An elegant poem on the culture of plants and flowers.

1796. Herebuschias, Conradus, counsellor to the
Duke of Cleve; was born in 1608, died in 1570. He was a notable theologian and wrote works besides his "Red Rustice" liber IV., which was published in 1570, and his Legum rusticum, et operarium per singulos Menus digesta, in 1595. The former was translated by J. Gooch, of Lincolnshire, with the following title:

Pouze Rooses of Husbandry, containing the whole art and trade of Husbandry, Gardening, Feasting, and Planting, with the antiquity and commendation thereof. Newly Englished, and called, "Red Rustice," London, 1578. Leaves 194, besides the Dedication, Epistle and Table at the beginning; and Ode English rules in verse, for purchase of books, at the end.

His authorities extend from the Bible and Doctors of the Church to Sallust, Pliny the Younger, Homer, Hesiod, etc., to the moderns as low as Ruelius, Fichius, Mathioli, Candusius, and F. T. Tragus. He mentions a list of his manuscripts, and other assistants, such as S. Nich, Malbe, M. Cap, Byngham, D. Fyningham, Vezetaw, M. Fitcher, W. Limeb, M. Lambert, M. Tauer, M. Thotho, Whenthall, M. Re, Diering, M. Hen, Brockhull, M. Franklin, H. King, Richard Angel, H. Danby, J. H. Frant, J. Hothie, Phil. Rattipulat, Kennewh Daforth.

The work is in dialogue. The persons are, cone, a gentleman retired into the country; Rigo, a curé; Metilla, wife of cone; and Hermes, a servant.

SUBJECT. 3. Works on Gardening published in Italy, exclusive of Translations.

7694 A considerable number of books on rural affairs have been published in Italy; but there, where garden and field culture are so nearly allied, gardening and agriculture have been so blended by the writers, that it is difficult to know under which department to include the books. The best work for giving a general idea of the state of culture in Italy is, the *Annali dell’Agricultura,* 22 vols. 8vo. by F. Re. 1809 to 1814.

1546. *Alamanni, Louis,* a Florentine gentleman, an eminent poet, born in 1495. Having conspired against Pius II (Pope Clement VII), he took refuge in France, where he was well received by Francis I, and sent in embassies to several courts. He wrote several poems, besides the following, and died in 1555. Della Cultivazione. It is translated into French with the title of *Georgique Italiane.*

1808. *Barelle, Giuseppe.* Descrizione de’ frutti e nocci e sospetti, con figure colorate. Milano, 1807, in 4to.

1809. *Re, Filippo,* librarian to the Patriotic Society at Milan, afterwards in the employ of govern- ment, at Turin, where he died in 1820 or 21. He wrote a great number of works on rural and econom- ical subjects.

1. Lettera su alcune particolarità osservate nella coltivazi- one dei giardini dei Milanesi. Milano, 1811, in 8vo.

2. Lettera su alcune particolarità curiose prodotti che volgare- mente dicono rose di queria, e sulla microhronia. Vertina, 1815, in 8vo.

5. Annali dell’agricoltura del regno d’Italia comunilati in Gennaio 1806, e terminati in Giugno 1814, 66 parts, forming 22 vols. in 8vo, with about 30 plates.

7. *L’Ortolano dirozzato.* Milano, 1811, 2 vols. in 8vo. con figure.

1812. *Spadoni, Paol.* Delle staminali, piante conservazione e conservazione delle siepi, con il disegno per ben far formare. Venezia, in 8vo.

11. *Candoli, Luigi.* L’Argentina Botanico. Turin, 1815-14, 6 vols. in 8vo. fig.

1815. *Gautieri, Giuseppe,* Inspector-general of the royal forests of Lombardy.

1613. Maresius, Jean, died at Leyden, in 1613, in the flower of his age.

31. Chuy, Ongier Augurius, author of some works on minerals and insects.

Memoir on the mode of preserving and sending over in good condition foreign bulbs, roots, herbs, plants, shrubs, seeds, and fruits. Amsterdam. Svo.

1699. Vander, Groen, I, gardener to the Prince of Orange.

Le Jardinier Hollandais, with environ deux cent modèles de parterres à fleurs et autres; lauriers, pavillons, pavages, plates, fruitières, et clôtures de laurier et de hortensies solides. Amsterdam. 4to.

1707. Munguis, Abraham, physician, and professor of botany at Groningen; born in 1626, died in 1699.

De cura et cultu plantarum. Amstel. 4to. 556.

1718. Casure, D. H.

De Rekeningtye hovenier (the Royal Gardener.) Amsterdam, fol. p. 121, plates.

1760. Comminck, John, a botanist, was born at Amsterdam in 1629. He succeeded his father as one of the magistrates at his native city, where he formed a new botanical garden, and died in 1692. His nephew, Gaspar Comminck, a physician, was appointed professor in botany, and director of the garden at Amsterdam.

1762. Van Sterbeek Francis.

Culturciatica, of regeringe der nyberischen boomen. (Of the cultivation of the orange tribe.) Antwerp. 4to. p. 326, 14 plates.

1763. Ostei, ou Ostei, Henry van, curator of the garden at Leyden.

Translated into German and French; and into English, as 2. The Dutch Garden, &c. Lond. 1710. 4to.

1715. Anon.

De nieuwe nauwkeurige Nederlandse hovenier. (The New Improved Dutch Court Gardener.) Leyden. 4to. p. 286, plate.

1721. Du Viger, Jean, supposed to be a French Protestant refugee.

Le Jardin de Hollande planté et garni de fleurs, de fruits, et d'arangeries, &c. Le tout après une longue expérience, mis au jour pour l'édification publique. Amsterdam. 12mo.

SUBSEC. 5. Works on Gardening, published in Sweden, Norway, and Iceland, exclusive of Translations.

1769. Scandinavian books on gardening are few, and chiefly by Linneaus or his pupils. A knowledge of the present state of culture in Sweden is best obtained by reference to the transactions of the Stockholm and Upsal Academies.

1817. Pindemonte, Ippolito di, an Italian poet, who has spent some time in England, and Luigi Mabia, a gentleman of Lombardy.

1817. Anon. An Accurate Agriculturist for Campi, Orti e Giardini, with all the rules of the cultivation of the fruit set out in a complete manner. Amsterdam. 12mo.

2. La Cottura dei fiori a seconda del clima Lombardo. B. 1817. 12mo.
tunate, as to put an end to this stupendous project. A dreadful fire having broken out in Upsal in 1701, among its ravages re- mained unsaved. The time of the work had been removed. These are, of course, extremely unusual circumstances.

1686. Rudbeck, Olaus, filius, the son and successor of the professor of the same name, was born at Upsal, and took his doctor's degree at Utrecht, and in 1720 joined Berzelius in founding the Swedish Academy of Sciences, the memoirs of which learned body contain a number of his dissertations on sub- jects which have immortalized his name. He also published some works on the plants and animals mentioned in Scripture. He died in 1740.

1729. Linnaeus, or Von Linne, Charles, was the son of a clergyman at Rasha help in Sweden, and born there May 13, 1707. He was educated at Lund, from whence he removed to Upsal, where he was appointed to read lectures on botany, in 1730; and the year following he received a commission from the Academy of Sciences, to travel in Lapland and Norway. He paid his journey towards the art of assaying metals, on which he afterwards delivered a course of lectures. In 1735 he went to Harderwyck, in Holland, where he took his doctor's degree in 1737. In 1740 he founded the Hortus Cliffortianus, the introduction of Boerhaave, superintendent of Mr. Clifford's garden, at Harendecamp, of which he drew up a catalogue. While in this situation, he published also his Flora Scandinavica; after which he visited England. On his return to Holland, he continued his Genera Plantarum, and was chosen a member of the academies of Utrecht and Upsal, and soon afterwards he laid the foundation of that at Stockholm. In 1740 he was chosen professor of medicine at the former place, where he undertook the reform of the botanical garden, to which he gave many valuable exotics. In 1745 he published his Flora Suecia, which was followed by the Fauna Suecica. At this time his merit was so well appreciated, that a medal was struck to his honor, and he was appointed architractor to the king. In 1749 appeared his Materia Medica; and in 1751 he published the Species Plantarum, an splendid publication came out in 1754, with this title, Museum Regis Adolphi Frederici, comprising a description of the natural curiosities in the royal museum. This work, passing through the press, Linnaeus was honored with the order of the Polar Star; and in 1756 he was ennobled. In the mean time he prepared for publication his Species Plantarum, which was followed by the Systema Naturae. This illustrious naturalist died at Upsal, Jan. 10, 1778, and his remains were interred with great solemnity, in the cathedral of that city, where his portrait is erected as a monument to his memory. His son, Charles Linnaeus, born in 1741, became demonstrator in the botanic garden, and in 1766, professor. He was ill used by his mother, which is supposed to have hastened his death, in 1783. His sister, Elizabeth Christina, discovered a luminous property in the flowers of nasturtiums, which was followed by the

5. Handling om skogers plantning. (Treatment on planting woods.) Upsal, 1721. 8vo.
7. Triewald, Martin. Anmärkningar utländska frö och andra planter-

ande i Sverige. (Remarks on exotic Fruits and other Garden Plants in Sweden.) Vetensk. Acad. Handling, 204. 1727.
8. Rudbeck, Johan Ernst, in the forest, was born in Finland, in 1715. He became professor of botany at Abo, and in 1747 went to North America, for the purpose of introducing the country to the well tried, and remained two or three years, and then returned to Abo. He afterwards made an extensive tour in Russia, with the same object, and died in Sweden in 1759. His works on Flora Americana were translated into English by Forster, in 1771.

1. Almanna anmärkningar wi den Kroyhöf trädgårds anlägg. (Some remarks on the laying out of a kitchen and Fruit-Garden.) Abo. 4to. p. 8.
2. Om norrländska och Finland trädgårds anläggande i Finland. (On the Practicability and Advantages of laying out Kitchen and Fruit Gardens in Finland.) Abo. 4to. 1740.
3. Dissertatio possibilim varia Vegetabill, exotic fabrises omnium, a nostris statu in Finlandia colentes. Abo, 4to, p. 11.
4. Utskott till en blandestad av inhemska växter. (Sketch of a Flower Garden of Native Vegetables.) Abo, 1746. 4to. p. 15.
5. Anmärkningar om vara Farnus Gran-skogens omnma, ward, ifje dera alfär. (Observations on Field and Grass Woods, &c.) Abo, 1757. 4to.
6. Anmärkningar蟑蟑 de olika关键技术 Av Exotiska. (Remarks on the Planting of Fruit Trees in Finland.) Abo, 1757. 4to.
7. Academisk AFhandling om med allt underhälla och oka skogsväxten i Finland. (On Oak Woods in Finland.) Abo, 4to. 1748. 4to. p. 4.
12. Bergius, Peter Jonas, a physician, and professor of natural history at Stockholm, published several botanical works, and a Materia Medica; died 1729.
14. Hellenius, Charles Nicolas, professor of botany at Abo, in Finland; died 1795.
15. Nicole anmärkningar om träfritrunder skildel i Finland. (On nurseries of fruit-tree plantations in Finland.) Abo, 4to. p. 15.
17. Thunberg, Sir Charles Peter, M. D. professor of botany in the university of Upsal, author of the Flora Japonica, and various papers in the Linnaean Transactions.
18. Omtalning om Planting der Løvende Gardesgard. (On planting Hedges, &c.) Upsal. 4to. 1780.

19. Om Hedvagen, Planting der Løvende Gardesgard. (On planting hedgerows, &c.) Upsal. 4to. 1780.
SUBSEC. 6. Works on Gardening, published in Poland and Russia.

7697. Of original Polish or Russian books on gardening there are very few; but a number of translations were made in Poland during the early part of the 18th century. There are agricultural transactions published occasionally by a society at Warsaw, which, with the transactions of the Economical Society of St. Petersburg, may be considered as the best books for obtaining some idea of the state of culture in these countries.

1785. Samborsky, a Russian poet, author of a number of works chiefly in verse, and of a poem on gardens, which has been translated into French, with the title Le Jardin de Samborsky. 8vo.

1780. Georgi, a physician, and member of several learned societies. Description de la Ville de St. Petersbourg et des Environs. Petersburg. 8vo.

1818. Lomonosov, a Russian poet and miscellaneous writer, author of a poem on glass, and the advantages resulting from its use in a northern climate. The subject of hot-houses forms a considerable part of the poem.

1808. Cartoryska, Princess Isabella, a lady of one of the most ancient families in Poland in the royal line. She spent a considerable time in England, where she acquired a taste for the modern art of laying out grounds, introduced it on her estate at Lublin, and wrote the following work on the subject.

Mysli Rozcm o Sposobie Zakladania Ogrodow, etc. (Thoughts on the manner of Planting Gardens.) Warsaw. 4to. plates.

SUBSEC. 7. Works on Gardening, published in Portugal and Spain.

7698. The transactions of the royal agricultural society at Madrid, are almost the only recorded source of obtaining any knowledge of the state of culture in Spain.

1785. Cavanilles, Antonio Joseph, an eminent botanist, author of various works, and among others, of Figures and Descriptions of the Plants of Spain. (De la Juncia avelleda, ó chufas of Valencia. (Anales de Ciencias Naturales, tom. ii. 251.)

SUBSEC. 8. Works on Gardening, published in North America.

7699. A number of American essays are connected with gardening will be found in the agricultural transactions of the Philadelphia and New York societies, in the transactions of the Society of Arts of New York, and in Dr. Dean's New England Farmer's Dictionary. Cobbett's American Gardener may be considered as affording a tolerable picture of the state of gardening in the United States, where it appears the long and severe winters are material drawbacks to every branch of the art.

1796. Petkaeus, Joseph. A Treatise on Planting, from the origin of sowing to cultivation, 2d edit. Basutere, St. Christopher's. 4to.

1806. Mr. Mahon, R., an American seedsman. The American Gardener's Calendar. 12mo.

View of the Cultivation of Fruit-trees, with the Management of Orchards and Cider, with accurate descriptions of the most estimable varieties of native and foreign Apples and other Fruits, cultivated in the United States of America. Philadelphia. 8vo.

CHAP. V.

Of the Professional Police, and Public Laws relative to Gardeners and Gardening.

7700. By professional police, we mean those associations which gardeners have formed, at different times, for mutual benefit or instruction, or the improvement of their art; by public laws, those of the legislature.

7701. A fraternity of gardeners, we have already remarked, has long existed in Germany as regularly organised as that of masonry. A fraternity also exists in France, but less extensive and systematic. Their principal lodge is at Versailles; the confréres de St. Fiacre, being there, as Neill observes, to France, what "Adam's lodge of Aberdeen is to Scotland." There are also a few similar fraternities in this country, who hold meetings, and have secret signs and other rites nearly similar to those of masonry; but these societies have no systematic connection like those of Germany. From masonry they have undoubtedly taken their origin; but how, when, and where, and for what object, in the first instance, though we have corresponded with competent persons in all parts of the kingdom, we have been unable to ascertain.
7702. The oldest gardeners' lodges seem to be those in Aberdeenshire, and Adam's lodge, held in the city of Aberdeen, is considered the oldest in Britain; there is another of nearly equal antiquity, called Solomon's lodge, held in Banff. These lodges profess to be for the mutual instruction of the members in their art; for the assistance of brethren in distress; and for the benefit of travelling members. The first object is attained both by secret instructions, and also by competitive exhibitions of garden productions, as flowers and fruits; the second, by annual subscriptions, from which a fund is formed, managed by a committee of the society; and the third, by signs and pass-words, as in masonry. They have a general meeting, formal procession with symbols and flowers, and afterwards a feast, once a-year. There were formerly a number of gardeners' lodges in Scotland, and there are still a few besides those of Aberdeen and Banff, but chiefly confined to the counties of Aberdeen, Forfar, and part of those adjoining.

7703. The principal Scotch gardeners' lodge, though it has no connection or control over the others like the metropolitian masons' lodge, is the Caledonian lodge of Edinburgh, founded about the end of the last century: its object is the same as that of the Aberdeen lodge; but it has no shows of flowers, or other garden productions. Their meetings are respectable, their processions pompous, and their funds considerable.

7704. There are very few gardeners' lodges in England; the only one of which we have been able to obtain any distinct account is "Adam's Lodge, of London," founded June 4, 1781, of which the rules and orders have been published. This lodge is described in the Rules, &c. as a "Fraternity or community for improving the art of Gardening; to establish a fund for the mutual support and relief of each other in the time of sickness, lameness, or distress; and also to ascertain the characters and abilities of such gardeners who shall belong to, or may be recommended by this society, to obviate the difficulty so commonly complained of by the nobility, gentry, and others, of obtaining skilful and experienced persons to undertake the employment." At present it consists of about one hundred and fifty members, and is on the decline. The allowance to the sick or disabled has been gradually diminished from insufficiency of funds; and from having been originally fixed by a random guess, instead of estimations of the value of lives, &c. as ought to be done in all benefit societies.

7705. Gardeners' charter. About the middle of the last century, Lee, Gordon, Russell, and Malcolm, all Scotch gardeners, commenced their nurseries at Hammersmith, Mile-end, Lewisham, and Kennington. Their success excited the jealousy of the established commercial gardeners, who, between 1760 and 1770, held several meetings, and entered into resolutions not to employ young men from the north. These resolutions were not long adhered to; but a tract, entitled Adam armed (see p. 1106. A.D. 1760), published by this association at the time, shows the extent of what they intended. From this tract it appears, that James I. had granted a charter to certain persons inhabiting within London, and six miles of it, who were capable to educate and instruct young men in the art of gardening. This charter was granted in the third year of this king's reign, and renewed in the fourteenth; but in the tract alluded to it is stated never to have been put in force, and not to be sufficiently extensive; and therefore it is proposed, that a charter be granted to extend over the whole kingdom, to prevent more laborers and other unqualified persons from assuming the profession of gardeners, and thereby doing "great injury to the nobility's and gentry's gardens and plantations," as well as to proprietors who let ground to such as "undertake to furnish the market with eatables." Only a certain number of gardeners were to be licensed to take apprentices, and of these the number was to be limited, &c. This attempt at monopoly of skill does not appear to have met with serious attention, and all that resulted from the association, as far as we have been able to learn (from a gardener, Duncan, upwards of 90 years of age), was the partial exclusion, for a year or two, of young Scotchmen from a few of the nurseries and gentlemen's gardens near town, which were managed by Englishmen.

7706. The origin of florists' societies we have not been able to discover. It is more than probable that meetings for the display of fine flowers and the estimation of their merits, were first held at Norwich, where, as Sir J. E. Smith informs us (Supp. Encyc. Brit. art. Bot. 336.), a love of flowers, and a great degree of skill in their culture, had been introduced into that city with its worsted manufactures, about the middle of the sixteenth century. At all events, there were florists' feasts held there so early as 1637; a play called Rhodon and Iris, being extant, which was acted before the company in that year. (Linn. Trans. vol. ii. p. 226.) The next florists' meetings, it is probable, sprang up about London; and Nathaniel Rench, of Fulham, is said (Faulconer's Historical Account of Fulham) to have been the first who established them, probably about the end of the seventeenth century. According to Davey, florist, King's Road, whose father was also an eminent florist, and lived to be upwards of ninety years of age, the florists' feasts and meetings were at their greatest height about London, between 1740 and 1770. They were then attended by many noblemen and gentlemen, as the horticultural societies are present. They declined towards the end of the last century, but have since revived, and are
at present rather on the increase. The florists' meetings, and those of gooseberry-growers in Lancashire and the adjoining counties, are very numerous, and rather on the increase. When they were first adopted in that part of England is not exactly known. From the best accounts we have been able to collect, they were in vogue there in 1760, and are re-collected so far back as 1740. Some florists' societies existed in Edinburgh during the latter end of the last century; and on one of these the Caledonian Horticultural Society was founded. The principal florists' societies in Scotland are at Paisley.

7707. The principal modern societies for the encouragement of gardening are, the London and Caledonian Horticultural Societies, whose transactions are so frequently referred to in this work.

7708. There are few public laws specially formed for the two first branches of gardening, horticulture and floriculture; the general laws being quite sufficient for their protection. Robbing of orchards or gardens, of fruit growing therein, is punishable criminally by whipping, small fines, imprisonment, and satisfaction to the parties wronged, according to the nature of the offence. (43 Eliz. c. 7.)

7709. There are a number of acts relative to arboriculture, and especially against the cutting down of young trees. (See Tomlins's Law Dict. vol. ii. art. Timber.)

---

**BOOK II.**

**OF THE FUTURE PROGRESS OF GARDENING IN BRITAIN.**

7710. The improvement of gardening, like that of every art or commodity, necessarily depends on demand and production. These causes operate reciprocally on each other: a nicety of taste in the purchase of vegetables and fruits exposed in public markets, will occasion articles of better quality being brought there; and articles of a superior quality, by improving and rendering more fastidious the taste of the purchaser, will ensure the continuance of their production. In like manner, if those who have private gardens were a little more difficult to please in selecting a gardener, and in the quality of the produce sent to table, the consequence would be, an improvement in that produce, and more scientific gardeners. More scientific gardeners would surprise and delight, by their superior fruits and flowers, and the greater order, beauty, and high keeping of their gardens; and the habits of both parties accommodating themselves to this improved state of things, would be the ground on which to rely for its continuance. In this view of the subject, the future progress of gardening depends on two causes; the improvement of the taste of the patrons of gardening; and the improvement of the science and art of practical gardeners.

---

**CHAP. I.**

Of the Improvement of the Taste of the Patrons of Gardening.

7711. Improvement is the characteristic of civilised man, and implies progressive advances. Men rest satisfied with what they have, when they know of nothing better; and therefore, one of the first sources of improvement in the taste of the patrons of gardening, whether of the tradesman who has recourse to the public market, or the private gentleman who is in possession of a garden, is the increase of knowledge. The wealthy tradesmen of Dublin and Edinburgh should look into Covent Garden market in London; and, not to mention fruits, and forced or exotic productions, let them compare the cauliflowers and salading of the three markets. Those who have once acquired a taste for such salads of endive as are afforded in the London market throughout the winter, would not very readily reconcile themselves to the accetarious productions of Dublin and Glasgow during that season.

7712. The ignorance of the proper mode of cooking vegetables, and especially of dressing salads, which exists among the middling classes, is another retarding cause. A French laborer, out of a few leaves of dandelion and wild sorrel, which may be gathered by the hedge-sides anywhere, and almost at any time, will produce, merely by the aid of the common condiments, what the wives of the greater number of respectable British tradesmen have no idea of. There can be no great demand for a thing, of which the use is not thoroughly understood; and, therefore, an improvement in the knowledge and practice of cooking must take place among a certain class before much can be expected in the quantity, kind, or quality of the gardening articles which they commonly consume.
7713. The more general use of dessert fruit among the middle classes, is another requisite wanting for the improvement of horticulture in Scotland and Ireland. If fruit, physiologically considered, is less wholesome after dinner than before it (which is questionable), it is at least more so than where drinking is substituted in its place. To prolong the period of eating, and the conversation of female society, are not only objects which afford immediate satisfaction; but, by moderating the use of stimulating liquors, tend to ensure future health. But, even in England, where a dessert is universal among the independent class, there is a great want of nicety of taste: fruit is valued by many only as a symptom of the presence of wine; others contentedly use pears and plums that would be rejected at the most common French déjeuner; and many rest satisfied with melons and grapes, who, at almost no additional expense, might have pine-apples. Wherever the litter of four horses is at command, pine-apples may be grown in Baldwin's manner (2649. and 2698. &c.) with very little trouble to the gardener, and, indeed, at much less trouble than trying to have very early cucumbers or melons. But why speak of pines, when not one family in a hundred are properly supplied with mushrooms, which ought to be on the table in some form, every day in the year. On a small scale, the grand secret is, to employ a gardener who knows his business; and to direct his attention less to raising ordinary productions at extraordinary seasons, than to raising first-rate crops of everything in due season. On a larger scale, all ordinary and extraordinary things should be attempted that art and wealth can accomplish.

7714. A taste for fine flowers and rare exotics must be preceded by some knowledge of plants, or a taste for scientific botany, and the history, geography, and uses of plants. These branches of knowledge may be considered as gaining ground. A good deal also depends on the fashion of using flowers as chamber ornaments, and on having green-houses attached to dwellings; both are most agreeable and rational luxuries; and it is much to be desired that a taste for them was more general, especially in provincial towns, and in the cities of Scotland and Ireland.

7715. The taste for planting has attained a greater height, during the last twenty years, than any other department of gardening; the beneficial consequences of which are already powerfully felt in Scotland, and the exposed parts of England. An essential requisite in this department is attention to the future management, thinning, and pruning of plantations.

7716. The taste for landscape-gardening has been nearly dormant in England, during the last thirty years; in Scotland it has been more active, but not of the purest kind; little has been done in Ireland generally, though there are some patriots there, who have been active in improvement. A taste for deer-parks is not common in Scotland; and rare in Ireland. A park in Scotland is a grass field; and what in that country corresponds with the park of a mansion in England is a number of green enclosures lying contiguous to each other, and surrounded by strips or rows of trees. In Ireland a mansion and park is a naked house, in a naked grass field, surrounded by a stone wall. There are exceptions in both countries; and many lawns or sheep-parks in Scotland of considerable beauty. Besides, a union of pasturable wooded enclosures, as a park, may be very well defended on the principle of utility; but there can be no defence of the naked parks of Ireland.

7717. The taste for public gardens, as promenades and botanic gardens, seems on the increase; but unfortunately these are seldom founded on a sufficiently secure basis. The funds of the recently established botanic gardens have been generally raised by the subscriptions of a certain number of individuals, to whom, and to certain annual subscribers, the garden is alone accessible. Perhaps it would be better, if, as in the case of public promenades, the funds were raised by the whole town or community, and the garden thrown open to all, like that of Paris. Public unbragious promenades, either equestrian or pedestrian, are very desirable additions to all congregations of houses.

7718. Choice of a gardener. Very much of the comforts and pleasures which a private gentleman derives from his garden, and garden-scenery, depends on the qualifications of the gardener which he employs to manage them. It was formerly the practice, in books of gardening, to give directions to gentlemen how to choose a gardener. These might have been of use when the qualities desired differed little from those sought for in a common laborer; such as sufficient strength and health, and good morals, disposition, temper, &c. But every master can judge of these and other similar points; and for any gentleman who has not a knowledge of gardening to go further, would be more dangerous than useful. We are clearly of opinion, that in almost every case the best mode is to apply to a respectable nurseryman; to describe to him the sort of garden and garden-scenery to be managed, and the sort of productions desired, and to rely on his recommending a fit person for accomplishing the intended objects. If this person should not turn out so well as was expected, the nurseryman will be in some degree responsible for his conduct, and will feel doubly anxious to replace him by a more competent person.
7719. **Education** is generally understood that portion of knowledge which is obtained at schools; but we shall here use the term in a somewhat more extended sense, and consider it as the means which may be employed to render man competent for performing the part which he undertakes to perform in life with increased satisfaction to himself and others. Education may thus be considered as extending to everything which operates on the body or mind, from the earliest period of our existence to the final extinction of life. With this object in view, we shall consider in succession the professional, intellectual, moral, religious, physical, and economical education of gardeners, previously submitting some general remarks.

**Sect. I.** On the degree of Knowledge which may be attained by Practical Men, and on the General Powers of the Human Mind, as to Attainments.

7720. The knowledge of languages, history, geography, arts, sciences, and literature, which a gardener daily occupied with his profession may acquire, provided he begins at the commencement of his apprenticeship, and continues to employ his leisure hours in reading till he is twenty or twenty-five years of age, is by no means inconsiderable: not that he can, or need become learned; but, if desirous, he may become generally intelligent; render himself fit, as far as conversation is concerned, for good society; prove instructive and entertaining to others by his conversation; and provide a reserve fund of enjoyment for himself, by laying up a store of ideas for reflection in misfortune, disease, or old age.

7721. The terms knowledge and ignorance are entirely relative: the knowledge of a modern chemist's porter would have subjected him to be hanged and burned in the days of the first popes; and any bricklayer's laborer who reads the London newspapers, has more correct ideas on the principles of political economy than nine tenths of the nobility in Russia and Spain. It is impossible to set limits to the knowledge which may be obtained by those who are destined even to the most severe and constant labor. The intelligence of the miners in Scotland and Sweden may be referred to as proofs. The miners at Leadhills have a regular library and reading society; and the works they make choice of are not only histories, voyages, travels, &c. but even works of taste, such as the British classics, and best novels and romances. The degree to which knowledge will prevail among any class of laboring men, will depend jointly on their own ambition; on the demand for, or reputation in which, knowledge is held; and on the opportunities of acquiring it. A dull, stupid person, with little native activity, will never desire to know more than what enables him to supply the ordinary wants of life. Where the workmen of any art are required to have technical knowledge of any particular kind, they will be found invariably to possess it. Thus carpenters and masons require some knowledge of the mechanical principles of architecture, and working engineers of the strength of materials; and these kinds of knowledge are acquired by them without an hour's interruption of their daily labors. The contrast, the habit of evening study renders them more steady, sober, and industrious than other workmen; than bricklayers and paper-hangers, for example, whose employments require much less intellectual skill. If every cook-maid, before she could obtain a first-rate place, were required to be able to read *Apiculus Bedivirinus* in the original tongue, there would be no want of learned cooks; and if no gardener could obtain a first-rate situation who had not written a thesis in Greek, or who had not made the tour of Europe, there would soon be found abundance of gardeners so qualified. A Caledonian, when he comes to the low country, soon acquires the English tongue, and if he has been taught Latin, thus knowledge of languages. The servants at the mansions on some parts of the Continent, frequented by different nations, often acquire a moderate knowledge of three or four languages. A late custom-house officer on the island of Cronstadt spoke and wrote ten languages; and the bar-maid, at the hotel (de Lombrid) at which we lodged in Moskwa, in 1814, could make herself intelligible in Swedish, Russian, Polish, German, French, Italian, and English.

7722. The certainty of obtaining anything is to be impressed with the necessity of possessing it; either to avoid the evil of being without it; to satisfy the desires of others as to themselves; or, our own desire. There is scarcely anything that a rational man can desire that he may not obtain, by maintaining on his mind a powerful impression of the necessity of obtaining it; pursuing the means of attainment with unceasing perseverance, and keeping alive that enthusiasm and ardor which always accompany powerful desires. Even the most extravagant desires, when sufficiently powerful, are often gratified. To attain eminence, as a literary character, natural or experimental philosopher, mathematician, divine, lawyer, or physician, it is only necessary to have a powerful desire for that kind of eminence, and to apply unceasingly to the subject, and to that alone. All may not acquire, by the same degree of labor, the same degree of eminence; but any man by labor may attain a knowledge of all that is already known on any subject, and that degree of knowledge is respectable; what many never attain to, and what few go beyond.

7723. The grand drawback to every kind of improvement is the vulgar and degrading idea that certain things are beyond our reach; whereas, everything is attainable by the employment of means; and nothing, not even the knowledge of a common laborer, without it. There are many things which it is not desirable to wish for, and which are only desired by men of extraordinary minds; but let no man fancy anything is impossible to him, for this is the bane of all improvement. Let no young gardener, therefore, who reads this, even if he can but barely read, imagine that he may not become eminent in any of the pursuits of life or departments of knowledge, much less in that of his profession: let him never lose sight of this principle,—that to desire and apply is to attain, and that the attainment will be in proportion to the application.
Sect. II. Of the Professional Education of Gardeners.

7724. In order that a professional man should excel as such, every other acquirement must be kept subservient to that of his profession. No branch of knowledge should be pursued to any extent, that either of itself, or by the habits of thinking to which it gives rise, tends to divert the mind from the main object of pursuit. Something, it is true, is due to relaxation in every species of acquirement; but judicious relaxation only serves to whet the appetite for the vigorous pursuit of the main object. By the professional education of gardeners, we mean that direction of their faculties by which they will best acquire the science and manual operations of gardening: and we shall suppose the young man to be instructed, to have no other scholastic education than some knowledge of arithmetic, and the first problems of geometry and land-surveying. The sort of garden which ought to be the scene of the days of apprenticeship should, if it can be so foreseen and arranged, be that which the learner is ultimately intended to possess or manage. As the great majority of young men who learn this art, are intended for serving-gardeners to private families; a private garden, where every department is respectably conducted, is the best to begin with. Here, or in any other garden in which he may be placed, he will have to learn the names of things, their uses in gardening, how to use them in the best manner singly, and how to combine their use in performing the different operations of gardening.

7725. The grand foundation for every kind of acquirement, is the cultivation of the faculties of attention and memory. Unless we pay attention to what is addressed to us, whether by the eye or the ear, it is impossible we can remember, because the sight or sound has made no impression on the memory, and without memory, there can be no knowledge.

7726. Many pass through life without seeing or hearing anything but what immediately concerns their avocations. It is a common thing for a person to walk out and return without being able to describe, or even mention, any one thing he has seen; or to read a newspaper without being able to tell what he has read, farther than to give some vague idea of the subject. All this is the result of neglecting to rouse and exert the faculties of attention to one single object or element. Attention, in fact, is one of the first things, therefore, that a young man should do, is to cultivate the faculty of attention, which he may have every hour of the day, by first looking at an object, and then shutting his eyes and trying whether he recoils its magnitude, form, color, &c.; whether he would know it when he saw it again, and by what marks he would recognize it. When he goes from one part of the garden to another, or is on a walk or journey, let him pay that degree of attention to everything he sees and hears, which will enable him to give some account of them when returned from his walk or journey; and let him try next day, or some days afterwards, if he can recall what he had seen then, or at any particular time and place.

7727. The attention must be exercised systematically, in order not only to impress the memory, and enable the observer or hearer to recollect objects, but to describe them. A thing or a discourse must be attended to, not only as a whole, but as a composition of parts; and these parts must be considered not only as to their qualities of dimension, color, consistency, &c., but as to their relative situation and position.

7728. To be able to give an account of a town or village, for example, the first thing is to get a general idea of the outline of its ground-plan, which may be done by looking from a church-tower or adjoining hill; next, its relative situation to surrounding objects; as what hills, or woods, or waters join it, and in what quarters; next, the direction of the leading street or streets must be noticed; then the intersecting or secondary streets; the principal public buildings; the principal private ones; where the lowest houses and narrowest streets are situated; and what is the character of the greater number of houses composing the whole assemblage.

7729. To be able to recall to mind or to describe the figure of any person before us for the first time, it is necessary to attend to height, either absolute, by estimation in feet and inches; or comparatively with our own, or that of any other person or object present at the time; to figure or shape generally, as whether tending to excellence or defect; then to limbs and features; in short, all, to the form and outline of the countenance, the complexion, and other details of the face. One untutored person looking at another with a view to recollect or describe him, would only stare; but an attentive and systematic observer would survey both the face and body in detail, and in such order as would readily occur to the mind on reflection. He would not, for example, after estimating the height, proceed next to the color of the eyebrows, but would take the breadth and shape, as more congenial to the accustomed train of ideas. The young gardener will apply these hints to recollection of parks, pleasure-grounds, walled gardens, hot-houses, and also to the study and recollection of individual plants.

7730. To be able to recollect and relate written or oral discourses, the same general principles will apply; the first thing is to attend to the object in view, and next to the order or form in which the whole is proposed to be treated or delivered; lastly, to the manner in which the details are filled up.

7731. The recollection of objects is more easily acquired by means of copying, or tracing a likeness of the object, and regarding it with attention and memory. The former by its systematic arrangement, and the precision of its details, tends to habits of order, accuracy, and distinctness, and to the ready discrimination and recollection of single or natural objects: the latter contributes to the same end, and also to the recollection of objects in groups or combinations, the inductive and more powerful kind of gardener's attention to drawing, even with a view to general improvement, independently of their special utility in his profession.

7732. The recollection of names and numbers is a more mechanical process than the recollection of objects. Names are either descriptive, that is, when they consist of a word, or are composed of words which describe something of the object to which they are applied, as Longtown or Hillhouse; or they are arbitrary, meaning nothing, or nothing now known or definable, as William, Thomas, &c. The first are of easy recollection, because, even though the object may never have been seen, its image may be presented to the imagination by the name, as a town of great length, and a house on a hill top; the second are only to be recollected by seeing the objects to which they are applied, and then associating in the mind the name with the thing; or by seeing the description or portraiture of the objects, and associating the name with these; or by finding a resem-
blance between the new name and a known name, as William, wild yam; Thomas, to mass, &c.

7733. The principal names which a gardener has to recollect are those of plants; to assist him in this knowledge, the etymologies of all the generic names, and of the specific names, which are substantive, is of great advantage. In the case of imperfect names, the last art of Linnean science, is often understood and recollected. The generic names of plants and animals are of three kinds; those composed of words indicating something of the nature, or appearance, or uses, of the plant, as Gypsophylla, Helianthus, Linum, &c.; those composed of the names of some eminent Linnean associates, as Carolina, Gordonia, or after some town, as Colchicum; and those composed of native or local names, as Etlettaria, Acceda: the first is often recollected, because the nature, the sight of the flower, or the recollection of its image or its uses, will recall to mind the name; the second may be recollected by considering who the name-father was, and by associating his figure and some characteristic particular with him. Thus Jordan was a nurseryman at Mile-end, a short, lame, sailor-looking man, who dressed in blue trousers, chewed tobacco, and was without offspring; it is easy to imagine his wife reproaching him with the last circumstance, while he pointed to Cordonia Lasianthus. All those names, whether of science, or those which occur in the common intercourse of life, as of persons and places, are to be recollected on the same principle; that is, either by the name itself calling up an image, by its resemblance to some other name already known, or by forming an association between it and some known or familiar visible object; and the more ludicrous the associatively, the better will it be recollected. In forming these associations, it is essential that the object employed to aid the memory be one capable of being seen; to associate any particular object with a sound, smell, touch, or taste, would give little aid to the memory; and to associate it with abstract nouns or ideas, none at all. If I am told that the Dutch merchant Schimphenninck was a very wealthy or religious man, that will not assist me in recollecting his long name; but if I say to myself there is some resemblance between Schimphenninck and skim-milk-pen-and-ink, the resemblance may enable me to do so; or if I have recourse to a Dutch dictionary, and discover that schimmel is grey, and phenninck a penny, I have greypenny, as a synonym, which, with the operations the mind has undergone in getting at it, will most probably impress the original name on the memory. If a Highlander tells me his name is Manpherson, I immediately interpret it mac-pearson—mac parson,—son of a parson—son of a Catholic priest and a Highland maid.

7734. Figures may be recollected by gardeners with readiness and certainty. For all numbers not exceeding 24 they have only to associate the figure with the name of the corresponding Linnean class, or with one of the plants of it. Thus, if a lad in a nursery is sent to the fruit-tree ground for plants of number 19 and 21 of pears, he has only to think of Syngenesia and Monocæa. For all numbers exceeding 24, and under 500, he may make use of the terms of the first ten orders, in addition to the 24 classes; and thus, No. 241 will be Cryptogamia monogynia, 249 Cypreg. enneaephygia, 208 Gynandria octogynia, and so on. To any one but a gardener or botanist, this mode of recollecting numbers has no advantages over any ordinary system of artificial memory; but as there can be no gardener to whom these classes and orders are not perfectly familiar during the whole period of his life, or at least of his practice as a gardener, to him it is superior to all the artificial systems. It is easy to add to the certainty of remembrance by associating the figure of any known plant or plants belonging to the class or order; thus, for 24 he may think of Osmunda regalis, for 245 Osmunda regalis and Daucus carota, or a fern-frond and a carrot-leaf; for 16,213 he may think of a rosegay composed of a Cana glauca, Narcissus triandrus, Olea fragrans, and Rosa provincialis, or he may fancy himself planting these plants in a row or in a pot. If a gardener rides through twenty turnpike-gates in a day, he may recollect the pass-number of them all. He has only, in passing through them, to place a pot of the indicating plants on each of their gate-posts.

7735. Numbers may also be recollected by gardeners by their going through the operation in imagination, of cutting them on a number-stick, either by the common (fig. 160.), or by Seton's method. (fig. 161.) Names may be recollected in like manner, by their going through the operation mentally, of writing or printing them, or writing them in some particular hand, or imagining how some particular friend, with whose handwriting they are acquainted, would write them. They may be supposed to be written on any scrap of paper, or against the day of the month in a common pocket-book, or what is preferable, after the last entry made in the pocket memorandum-book (7741.), to be afterwards described.

7736. The memory, both as to figures and words, may also be materially assisted by studying the postures of the human figure, corresponding to the first ten Italic numerals, and the letters of the Roman alphabet. Plates of these are to be had in the juvenile libraries. Some useful hints on the subject of memory will be found in Feinagle's work on the subject, and especially in a tract by Jackson, in which Feinagle's system is greatly improved; but the machinery of both systems, though they enable a student to recollect an astonishing detail in a short time, yet, like other complicated machinery, it soon goes out of order when not in constant use. It is, therefore, unfit for practical men.

7737. The uses of things and their history, is the next thing which a gardener has to acquire. The uses of the implements, tools, utensils, and machines of gardening, he will acquire by manually exercising them in performing the labors and operations of gardening under the direction of his master. He should not only know how to use them, but how to use them in the best manner; and also the history of each implement or machine, derivation of its name, why one form is preferable to another; in short, he should know the rationale of the formation and operation of all of them. The essential part of this he may acquire by reading Part II. of this work, and the rest from the study of the principles of mechanics, and by conversing with intelligent carpenters, millwrights, etc.

7738. The uses of the common garden plants he will find in the third part of this work, Books I., II., and III., something more he will find in Book IV., and for the rest he must have recourse to books on cookery, medicine, chemistry, and farming, which go more into detail. Much information on all the arts con-
nected with the vegetable world will be found in our Encyclopaedia of Plants, and in the Encyclopaedia of Agriculture.

7759. The study of systematic and physiological botany must go hand in hand with practical acquirements; for which, and also for forming an herbarium, he will find general information in Part II. Book I., and for more minute details, he may consult the authors there referred to. Some idea of vegetable chemistry and geology he will obtain from Books I., II., and IV. of Part II.; and also of the different insects and vermin which are enemies to gardens and garden-productions. The study of landscape-gardening, as being the highest part of the profession, should not be attempted till the apprentice has made himself master of the three departments which precede it.

7740. A knowledge of the weather and the seasons, so as, in some degree, to be able to predict them from signs, is an important part of a gardener's acquirements. Our observations in Part II. Book II. will aid him in this study, and he should also keep a weather-book, or naturalist's, such as we have already suggested. (2349.)

7741. A pocket memorandum-book, for taking notes of everything interesting, whether professional or general, is a useful help to the young gardener. He should begin this sort of memorandum-book with his leaving school; and he will probably find it useful to continue it all his life after. Its size should be small octavo, to suit the pocket; it requires no ruling, but a line across the page half an inch from the top. In writing on one page, the opposite one should always be left blank for corrections and additions, for sketches, or for taking down temporary memoranda in pencil. The following may be considered as a specimen, in which it is to be particularly observed, that a margin is left on the written page, on which margin each article is begun with a word written or printed in large letters. These words, thus conspicuously placed, serve as an index to each article, and in future reference will be found of material use, as they can be glanced over like the words in a dictionary. Any thing to be inserted, should always be done instantly, or never later than the same day. If it is done out of doors, it may be written on the blank page in pencil, and afterwards copied on the opposite page in ink.

<th>Pocket Memorandum-Book of J. Goff, Apprentice, at Aubrey Hall.—January 27th and 28th, 1824.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>PEAS.</strong> — Last night's frost and this day's sun have killed the peas in the south border; but those sown in the north side of the wattled hurdles escaped, being shaded from the sun.</td>
</tr>
<tr>
<td><strong>LIZARD.</strong> — Caught a new species, and took it to Twigg. It had no tail, which convinced him it must be a distinct species.</td>
</tr>
<tr>
<td><strong>ROSES.</strong> — Idea of a conic iron tree, covered with any of the climbing roses, all over inoculated with monthl y roses.</td>
</tr>
<tr>
<td><strong>PARSNEPS.</strong> — Gurkin O'Doolittle caught distilling parsnip whiskey in the ten-shed; discharged without a character. His still two water-pots placed top to top, and closed with a wet cloth: the top kept cool by pouring water on it.</td>
</tr>
<tr>
<td><strong>NEW IDEAS.</strong> — Torell Jos, the parson, called; says there are two ways of getting new ideas; by shuttling what ideas we have together, like a pack of cards, (which is to be done by a fine glass of wine, opium, or tobacco,) when new combinations may occur to the mind accidentally, or by a studied selection of ideas suitable to the subject on which it is desired to invent, which can only be done by scientific persons, as Sir H. Davy in his invention of the safety-lamp.</td>

7742. Apprentices are often required to keep a written journal of work done in the garden for their own use, and this may be advisable in cases where no regular books are kept by the master; but where such books and tables are kept as we have recommended (2538. to 2540.), the apprentice performing his part in making entries in, and daily seeing them, need keep no other books for his own improvement than a naturalist's calendar (2340.) and the journal or memorandum-book just described. In the last he can enter such facts belonging to gardening as are commonly entered in gardeners' journals.

7743. Progress when a journeyman. An apprentice, besides studying his art in the garden of his master, should, as often as may be, visit those of his neighbors, and observe what is going on there. His apprenticeship completed, he should move to a different part of the country, performing the journey leisurely on foot; botanising and collecting insects and minerals, and visiting every distinguished garden on his way. When he settles, it should be in a different kind of garden to that in which he was before, and there he should continue a year, and then remove and travel to another part of the country, and settle there a year, and so on as already suggested (7380.), till he attains his twenty-fifth year, when he may undertake the situation of master. During the whole period in which he is journeyman, he should be steadily and unceasingly employed in improving himself, first in his own art, and the branches of knowledge, as botany, natural history, chemistry, weather, &c. on which it more immediately depends; and next, if his ambition permits, on general subjects of literature, arts, and sciences.

**Sect. III. Of the Intellectual Education which a Gardener may give himself, independently of acquiring his Profession.**

7744. Self-education may be carried to a greater extent by a gardener than by almost any other artisan. No gardener, in our opinion, ought to be employed as a master under the age of twenty-five years. Suppose him, therefore, to be put an apprentice at
fifteen, he has ten years in which to acquire his profession, and generally to improve himself. In that period he may not only acquire his profession, but, according to the extent of his ambition and application, a considerable degree of knowledge on almost every subject. Everything, as we have more than once observed, depends on his ambition; without this he will not even acquire his profession, and at all events will find no leisure time for any other kind of improvement. When we consider, however, that the labor of a gardener is not severe, and that it is only during the hours of daylight, the time he has for self-improvement is very considerable. It may surprise some when we state, that this time equals (taking the whole year) that employed in study by professional students at colleges. A gardener, in the shortest day, begins work at eight o'clock and leaves off at four o'clock; which, allowing two hours for breakfast and dinner, gives six hours of labor; in the longest day he works only ten hours, and therefore it will not be far from the truth to consider eight hours per day as the average duration of his labor throughout the year.

Dividing the twenty-four hours which compose the day in three equal parts, we have eight hours for rest, dressing, and undressing; eight hours for labor, and acquiring the practice of gardening; and eight hours for refreshment and study. On comparing this time for study with that which is usually devoted to it by young men at college; not the generality of young men, but those even who attain to eminence; we will find a difference very inconsiderable. The student requires the same time for rest, and at least two hours more for dressing and undressing (say ten hours); for breakfast he requires an hour; dinner and tea, at least three hours; and for exercise (which if he neglects he will soon be unable to study at all), at least two hours; in all, for exercise and refreshment, six hours; which added to ten of rest and dressing, gives eighteen hours, leaving exactly the same number of hours for study which every gardener has, taking the average of the year. It is true the eight hours of the gardener are subject to the time employed in eating; but that may well be considered as compensated by the knowledge of botany he acquires in the garden during his hours of labor. Add also, that the gardener may (unless his health forbid) draw still more time than we have mentioned from the hours of sleep; we think it will not be denied, that, taking all circumstances into consideration, he has as much time as studious men, taking the average of the year, usually devote to study.

7745. The branches of education best deserving a gardener’s attention are next to be considered. As one branch of knowledge is as much as any person ever does or can excel in, and as that branch, in the case of every professional man, ought to be his profession, it seems to us that a gardener ought not to attempt to excel in any other sciences; he is to make his study systematic, to the degree that circumstances may permit, with the whole cycle of human knowledge. If he attempts to do anything else, it is impossible, isolated as he must be, in comparison with others who study the same subject among abundance of books and fellow-laborers, that he can attain to the highest degree of eminence. It is impossible, for example, that he can arrive at great perfection, even in the study of botany, from not having an opportunity of consulting the herbariums and books which are only to be found in the metropolis. He may, however, and ought to, attain a respectable degree of knowledge, not only in botany, but also in the other branches of natural history; such for example as will enable him to refer any natural production to its place in the Linnean system, and describe scientifically any new production. But that he should be expert at chemical analysis, dissection of animals, solving problems in any of the higher branches of mathematics, or excel in painting, music, or poetry, is what we by no means propose, or think practicable, though we are convinced he may know something of all those subjects, and of all others on which there are published books.

7746. The source from which he is to derive his general knowledge, it may easily be conceived, is chiefly from what is opposed to profession; public lectures, men of talents and learning wherever he has an opportunity of conversing with them; artists, botanists, and others who constitute the facturers of every description; and also manufacturers, engines, mines, dock-yards, and all other works displaying human skill. But the grand source is books, and the question is how a journeyman gardener, whose wages are often less than those of a common laborer, is to procure them? Our answer is, borrow them; and make it a fixed rule to purchase no books excepting grammars, dictionaries, and other elementary works; and of these used or cheap copies. The head gardener will always be able and willing to lend his apprentices and journeymen a certain number of books; and the patron under whom they serve, will generally be found equally liberal.

7747. The sorts of books desirable to borrow, independently of those connected with the professional acquirements, such as treatises on Chemistry, Zoology, Mineralogy, &c. will depend on the degree of advancement. But there are the opinions of the Brith, who do not disapprove of the Encyclopaedia. One systematically instead of alphabetically arranged would be the best; but as most country libraries are now stocked with the Encyclopaedia Brit. or Rees’s Cyclopaedia, these must be taken till and executed one or the place of the Cyclopaedia Metropolitum, now publishing (but badly executed), finds its way into general use.

7748. The studies to be commenced with is next to be determined. It is necessary to premise here, that the mind, before it can derive much improvement from reading, must undergo a certain degree of culture. To improve by reading it is not sufficient to be able to read, we must be able to analyse language and discourse; to recognise the real or apparent object of the writer; and to trace the order of his ideas from the commencement to the conclusion. The foundation of this is the exercise of the faculty of attention, which is almost the first and essential aid to the understanding of languages and of languages. Another excellent help is the study of systematic natural history; a circumstance highly in favor of gardeners who are desirous of improving themselves in general literature; since, if they know their profession at all, they must have a tolerable knowledge of systematic botany, which gives the mind an orderly and systematic method of arranging knowledge, to hear gardeners, in other subjects, have no notion of the importance of general literature, applying the terms, genera, species, sub species, and varieties, to manners of thinking, or acting, to religion, weather, forms of governments, &c. For want of this preparation of the mind, there are many persons who have been well educated, and have received little benefit from it. Their minds are not competent or not habituated to view the subject which they read as a whole, but take a view of the general qualities and tendency. All they see of it is the parts as they pass before their eyes, their relation and connection they think nothing of, and the whole passes as it were through the mind, instead of remaining on it. Reading to such men, in comparison with those whose minds have been prepared by elementary studies,
may be said to resemble pouring water on ground with a hardened surface, in comparison to pouring it on soil which has been loosened with the spade.

7749. English grammar and a foreign language are suitable studies to commence with. Another excellent aid to forming the mind to precision and accuracy is the knowledge of quantities; for which reason we shall here briefly study geometry. For this purpose we will have for the first year a general reading, some species of personal accomplishments, and the requisite professional studies, are all that we would have an apprentice commence with, and this only in a certain order to be afterwards described.

7750. With respect to personal accomplishments, we would have dancing, fencing, boxing, wrestling, the infantry manual exercise, whist, backgammon, chess, the flute, and violin, attended to as far as opportunity offered; considering dancing, boxing, and the violin as the most essential objects. In most country-places dancing may be learned from retired farmers or gentry, and the flute, violin, the study of a schoolmaster. Dancing is the art of improving the gait, and habituating to good postures both in standing and sitting. To a man who has no other resources for advancement in life than such as are personal, every exterior acquirement is of the utmost importance. — These remarks will to many appear sufficiently extravagant; but it is very necessary for him who desires to be a certain extent master of these accomplishments as it were accidentally? Why then may he not improve them by art, if opportunity offers; or, if they are of use, why should he not seek occasion both to improve and extend his knowledge in this department.

7751. In study, as in all other things, much depends on the circumstances; the march of study is regulated, and constant, and as there is only a certain portion of the twenty-four hours which a gardener can devote to study, every moment depends on his employing every moment of that portion. To be convinced of what is lost by delay, let two persons commence walking along a road in company; then let one of them stand still for half a minute and the other walk on, and at the end of the half minute the distance at which the former will find himself from the latter will be found astonishing. Again, supposing them walking together, and that one, instead of walking along the road with the other, deviates and diverges from it — the distance at the end of half a minute, at which the deviator is found from the one who walked straight, will be greatly more than the former, because the former is required to return to the direct road equal to that taken to diverge from it, but when returned, the deviator will be a whole minute’s walking behind the other. These two simple experiments it would be well for two young gardeners to try, in order that the results may make a lasting impression on their minds, and let them afterwards think of them when they feel inclined to be lazy or dilatory, or to depart from the line of duty.

7752. To add in the economy of time, it is desirable to form some plan of study; where there is no regular plan much time is lost in hunting up what should begin with; and there is too much use of too long intervals of application to one thing; by which means a proportional relaxation is required, and the memory, being irregularly charged, will be less faithful. By a well ordered pre-disposition of studies, the time which would be lost in considering what would be done next is gained, and the student would get on as fast as if he made an effort to do these acquirements as it were accidentally? Why then may he not improve them by art, if opportunity offers; or, if they are of use, why should he not seek occasion both to improve and extend his knowledge in this department.

7753. To add in the economy of time, it is desirable to form some plan of study; where there is no regular plan much time is lost in hunting up what should begin with; and there is too much use of too long intervals of application to one thing; by which means a proportional relaxation is required, and the memory, being irregularly charged, will be less faithful. By a well ordered pre-disposition of studies, the time which would be lost in considering what would be done next is gained, and the student would get on as fast as if he made an effort to do these acquirements as it were accidentally? Why then may he not improve them by art, if opportunity offers; or, if they are of use, why should he not seek occasion both to improve and extend his knowledge in this department.

7754. Rigid pursuit of the object in view. If at any time, through business or over-sleeping, but a few minutes can be got in the morning, still these few ought to be applied in the usual channel; even half a minute is worth something; for in time that a man may walk half a mile, or read a page of his book, contains things of importance, and must very accurately be opened and a word looked at, and recollected, and even a word per day gained is worth something.

7755. Progress is gradual. It is impossible to gain any end either in self-improvement or any thing else, but all is gained by labor, and nothing is lasting but that which advances by degrees. The independence which even a very moderate knowledge of languages confers on the possessor, whether in general reading, or in reading foreign books, is invaluable, and amply compensates the trouble requisite to acquire them. To any person going abroad for profit or improvement, they are essential. It is commonly observed, that a period of years is requisite to acquire the ability to converse with children who learn it by compulsion, and is more or less the case as to everything they are taught; but with a grown-up and voluntary learner the case is widely different. We have known men in this country acquire one or two languages, after having attained their fortieth year; and the same degree of advancement is observable in the country.

7756. Books on grammar. In purchasing the grammars, that of Cobbett or Lindley Murray may be selected for the English; and for the other languages, any that can be got cheapest; the last remark will apply also to the dictionaries. To this day, books and words of Latin, French, and Spanish, and to the Greek, in books, in most languages may be had at book-stalls for a trifle; or by applying to a subscriber to the Bible Society, he will procure a New Testament in any living language, and also in Latin, Greek, and Hebrew, for two shillings or half a crown. Used copies of the Joanna Language Teetom, may be had at half price, or, in Latin, Greek, and Hebrew, very cheap.

7757. Plan of study for general subjects. The spare time after breakfast and dinner we devote to botany for the first three years, and the seven years afterwards to botany and other branches of natural history, gardening, and farming books. Thus the early part of the day is disposed of for the whole ten years, as far as to arrange the plan for evening studies. For this purpose we must have had, in the case of little study with these acquirements; and as far as possible devote two hours at some period of every working-day evening, during the first three years, as follows: of the first evening to drawing plans and architectural subjects; the second to arithmetic, mensuration, and land-surveying; the third, to
drawing landscape and figures; the fourth, to Euclid's Elements; the fifth, to drawing plants, flowers, insects, and minerals; and the sixth to mechanics and experimental philosophy. The remainder of each evening was spent in letters, both of composition and viewing letters in the style, and in penmanship; to miscellaneous reading, if possible, from an encyclopedia, assigning a due proportion to each kind of study or occupations.

7760. Holidays, when they occur, should be commenced with a language, as usual, and to be included in the general rotation for that branch; but the remaining part of the day we would dispose of in portions of one, two, or three hours, in bringing forward those evening studies which we had been least successful in during the week, or found ourselves most in want of for actual use. Holidays are a time when it might be desired for drawing; but it must be remembered that this light, yet goes on best with that of the sun. Nothing can be more mechanical than copying drawings, or drawing from nature, and there is nothing (but want of will) that can hinder every gardener from being a good draughtsman.

To paint in oil, or make highly finished drawings, valued as such, is quite a different thing, and not to be attempted but by such as have much leisure, or adopt that pursuit as a profession.

7761. The books necessary for general studies are, any authors on arithmetic, mensuration, and land-surveying; E. L. of Euclid, and of Young's Lectures on Natural Philosophy; or study the articles on the last subject in a good encyclopedia. There is no very good drawing-book for self-instructors, but some one may be borrowed, and those parts of any encyclopedia consulted with advantage in this business. For the latter, it is necessary, as in all reading, all the books required are to be borrowed, and chiefly, if possible, an encyclopedia, which ought to be read through volume by volume, and notes taken in the pocket memorandum-book (7741) of such parts as are considered best worth remembering.

7760. Conclusion. A great deal more might be said on this subject, did our limits permit; suffice it to add, that if a student only wills and exerts himself, everything will be found possible; difficulties may occur, and may retard for a time, but they will finally be overcome. The great thing is to be convinced of the importance of incessant application, by which any man may attain to eminence, and without which eminence was never yet attained. The profession of a gardener is, more than any other, favorable for mental acquirements; his labor is easy; his patron has a library; he has frequent opportunities in improving his language and manner, by being asked questions by his patron and his family, and other superiors who are educated and polished. He may also render himself useful to clergymen, medical men, and schoolmasters, by preparing them for what the nature in return he will receive useful hints, and the loan of books. A great object is, to accomplish all this, and yet to save some spare money for travel and accidents, which is to be done by great simplicity (avoiding what is meagre) in food and dress; by neglecting the use of such luxuries as tea, sugar, spirits, and such other articles as are much taxed; by purchasing used clothes, and never new ones before having arrived at the degree of head gardener, for the best dress; and by having, for daily use, dresses of coarse grey stuff, not enhanced in price by much ornamental manipulation, or by taxes. Though, in making these remarks, we have had in view chiefly young men, yet there is no period of life at which improvement may not be commenced, and attempted with a degree of success that will amply repay, though at a period under thirty, every thing we have proposed may be attained: a great deal, even at forty, and enough to meliorate and humanize life, beginning even at the latest period. Let the gardener never forget that though something may depend on his organisation, yet, that much the greater part depends on education — on his desire of raising himself, and on incessant application. To desire anything ardently is, in truth, to be inspired with the power of attainment.

SECTION IV.

Religion, Moral, and Physical Education of Gardeners.

7761. The subject of morals (morales, Lat. manners) regards the conduct of man towards others; that of religion (religio, Lat. devotion, devoted to), his opinions as to God or the nature of things; and that of physical education (physica, Lat. the knowledge of nature) instructs him in the art of preserving health.

7762. Morality and religion are usually treated as depending on each other; the latter is considered as the principal foundation of the former, and man is taught to be sober and honest, not only to avoid the punishment awarded by the laws of his country, but to avoid still greater punishment in futurity. But morality may and does exist apart from religion; for truth and justice, honesty and humanity, are essential to the existence of regular society. Debauchery of every kind is attended with the loss of reputation, and more or less of bodily health; those who despise, and affect to treat with contempt or ridicule, the opinions of the respectable part of society, are themselves despised and excluded from society in return. In the intercourse of society, a man always receives according as he gives; and as he treats others so is he treated himself. If he wishes to be dealt with honestly, he must be honest; and if he wishes to be respected by respectable men, he must respect them, and their conduct and principles. In short, independently of religious motives, it is necessary to be moral, in order not to be disreputable; and worth while to be highly so, in order to ensure confidence and respect. Whatever theory therefore the young gardener may adopt, there is only one practice which he will find to answer his expectations; and that is, the strictest regard to truth, honesty, sobriety, decency, and purity in himself; and respect for others, in proportion as these virtues appear in their conduct and conversation.

7763. The moral law of all countries is essentially the same; because, in the rudest forms of society, it is instinctive: but among more civilized nations and even among those in a comparatively advanced state, the more refined laws of morality are neglected. Though a Russian in St. Petersburg, where the people, from the boor to the czar, are the most religious in Europe, it is no discredit to a gentleman to lead a debauched life, or to pilfer trifling articles from another, or to steal from shops (Lyttel's Moscow, c. 342) and yet that in society, and in every public man, the enjoyment of every individual depends not only on a strict, but a refined morality; and men must not only be polite, but polite.

Politeness may be considered the ornament or finish of morals or manners; and though it is commonly thought to belong chiefly to the higher classes, yet it will be found both attainable and useful in a high degree, by every class, and by none more than the gardener. Polite and amiable conduct, like a good figure and address, recommend themselves at sight, and make at once an impression in favor of the man who possesses them. "Civility," Lady M. W. Montague observes, "is a sort of current coin which costs nothing and buys everything." The greatest genius and abilities will never procure a
The art of conversation, like all other arts, is only to be acquired by reflection and experience. The art of conversing is the mind with ideas; and every art, by its nature, is peculiarly connected with anodomy, history, and biography; the next thing is to adapt our conversation to the society in which we happen to be; and the last requisite is to endeavor to discover the precise part and quantum of conversation which we ought to supply.

Every master of a family ought to instruct the members of it in the art of conversation, and to advise them more especially to avoid all subjects that lead to argument and discussion. These are of little service to truth or instruction; because men are seldom convinced by arguments carried on in society. No one perhaps, among the Christian nations, is more particularly averse to the discussion of any subject, than the English. To them the side of the argument happens to be younger or of an inferior rank. Men may be willing to be instructed, who would not submit to be convinced; and some will consent to receive information, who would feel the wrong they might do to the idea of instruction. Elderly persons, however, and such as are of acknowledged experience and judgment, may sometimes be so cautious, that they will not yield, but even then they are to be suspected in which they correct, or contradict, or criticize; lest, as is often the case, they appear more eager to display their own superiority, than to improve and oblige the party addressed. The love of self is liable at every moment to break in upon and spoil everything; and therefore the grand object is to keep that feeling constantly before the idea, that the object of all conversation is to please. Three or four young gardeners, all eager for improvement, might practice conversation on this principle, by assembling occasionally, and either conversing as equals, or for the sake of variety and improvement, assuming characters. Two or three persons may take the part of parents of a family; one or two of servants, or children, and the rest of the persons who would be affected as equals.

Whist, chess, &c. For the purpose of being able to join in the amusements of society, we have already recommended the study of whist, chess, &c. These are essential personal accomplishments of every man who would find his way in society in England, where conversation is not nearly so well understood as it is in any country on the continent of Europe.

There are two things in conduct which the gardener ought most particularly to avoid, familiarity and expediency. When these qualities discover themselves either in manner or conversation, they are a certain mark of low birth and breeding. A low, ignorant man, if he receives the slightest civilities from a person, immediately conceives the latter to be a particular friend for him; and soon endeavors to turn this friendship to advantage, by asking to borrow money to forward himself in business, or requesting a place under government, or a pension. If a gentleman, or indeed any man, notices a low familiar woman, the latter immediately concludes he is in love with her; if he has daughters, he has come to marry one of them; and at all events, he is a particular friend to be biased and relied on in time of need, who will certainly advance the family in some way or other. Such is the self-love and ignorance of mankind betrayed by the vulgar; for familiarity proceeds from that sort of gross and simple refinement, that it does not involve any obligations, nor inducements in the most absurd hopes, merely because, if realised, they would tend to their profit.

An induced and polite man is not familiar with any one, because he knows that if he were to lay bare everything respecting himself he would lose respect; and he does not show an impertinent curiosity concerning other people, because it might hurt the susceptibilities of other persons. There is no idea more intimate than the idea of feeling, and this is out of the question with him, because he knows mankind too well, to suppose they will give him a valuable thing merely because he asks it; but even if there was a chance of getting it in this way, still he would not ask, because he might be asked for something still more valuable in return. In this way polite men are not subject to that grossness of conduct, which makes the greatest difference between the two sorts of men who are met with in the same place, who have no interest in each other, or who are not acquainted by main chance. Where a weaker and stronger party, as man and wife, parents and children, masters and servants, cease to act in such a way as to maintain a mutual respect, the stronger party is an obliging one of four, and therefore becomes a benefactor, and is not to be obeyed and hated, instead of being obeyed and respected. What is it that makes a man hate his wife's faults more than those of any other woman? first, he knows them better: secondly, he knows he must put up with them; thirdly, he knows that she knows his faults, and hates them more than she does the faults of any other man. All this arises from familiarity.

The want of mutual respect is the cause of many evils among the lower classes; it is the origin of almost all family quarrels, and of most of those between individuals; the cause, familiarity, ought therefore to be avoided, by all who would be respected; and a salutary restraint placed on all their feelings,
both of love and hatred, curiosity and communicativeness. Judicious restraint is everything as to over- 
coming bad or vulgar qualities; a man properly under its influence may be compared to a well trained 
tree; and as this figure is familiar to the young gardener, it may be well for him frequently to ask him- 
sel whether, supposing he were a cherry-tree, he would be reckoned one finely spread against a wall or 
an unplanted tree.

7773. Religion is a subject which we leave every gardener to arrange with his own 
conscience; only observing, that as it concerns only the man himself, and unless joined 
to enthusiasm and proselytism, can never injure others; every one should be left at 
liberty to think in this respect as he chooses. Let no one, however, consider that differing 
from others as to religion implies a difference in morality, or a neglect of moral principles 
and let every gardener consider well what we have before said on this subject. (7769.)

7774. Physical education. It may be supposed superfluous to say anything to gar- 
deners in respect to health. But the truth is, that since the general introduction of hot-
houses, the profession of a gardener has become in some degree different from what it 
was; and he is now subject to heats and colds, which are liable to bring on inflamma-
tory and rheumatic complaints. Being heated excessively in a hot-house, and cooled 
to a very low degree in the open air during winter, or in an ice-house (which is now in 
amost daily use in good gardens, for preserving fruits and vegetables) during summer, do 
not of themselves injure the constitution; but the evil arises from the partial operation of 
either extreme by which one part of the frame is cooled or heated sooner than another. 
By this the circulation and perspiration are unnaturally accelerated or diminished in 
these parts, and of course the action of the whole system deranged. When this takes 
place, the consequences are fever, costiveness, and often St. Anthony's fire, ague, rheumatism, &c. If taken in time, opening the bowels and the hot-air bath of the hot-
house, taking care either to go at once from it to bed, or to the dry-stove and green-
house, so as to cool gradually, will restore the system to order; if neglected, time, open-
ing and sudatory medicines, and probably the doctor, will be required. The principal 
danger is to be dreaded from the excessive heat and perspiration produced by working 
in the bark-stove or in pits, such as during shifting, syringing, &c. To guard 
against these, the operator should limit his dress at the time to a loose flannel shirt and 
wooden shoes, and when finished, should wipe himself perfectly dry before putting on 
his ordinary clothing.

7775. The foundation of all health is regularity in the time and quantity of food taken, and in the com-
mon evacuations. If these are strictly attended to, everything will go on well; if suffered to become 
irregular, everything will go wrong. The stomach is the primum mobile, as it were, of the consti-
tution; the cause, when disordered, of the most afflicting diseases, and the first thing to be restored in 
order to their cure.

7776. A strict attention to personal propriety and sober habits need hardly be mentioned, with refer-
ence to young gardeners who mean to advance themselves; to suppose, indeed, that they would indulge 
in inebriety, or in alehouse society, is so entirely out of the question, that we shall not enter on 
the subject.

Sect. V. Of Economical Education, or the general Conduct and Economy of a Gar-
dener's Life.

7777. A gardener, who has attained his twenty-fifth year, and has carefully employed 
the leisure time of the preceding ten years in improving himself, will now have formed 
his judgment on most subjects; and be able to determine a general plan for the future 
economy or management of his life. A man may be learned, or have a genius and taste 
in his profession, without having that taste or judgment as to the economy of life which 
leads to fitness and propriety of conduct, and will induce him to fix on an object to be 
acquired, and devise and pursue rational means of obtaining it. Bad taste in the common 
business of life may lead to bad plans, to a desire to acquire property too rapidly, to 
gambling, to match-making, to quackery, and, probably, even to crime and disgrace. 
The principal cause of this bad taste is, that what is called education is much too 
limited in its objects; or that part which is commonly left to parents or masters is but 
very imperfectly supplied. A youth ought not only to be instructed in the different 
laws by which the conduct both of individuals and society is regulated, but also in the art of 
forming a plan for the management of his talents, so as they may best contribute to his 
happiness. Nothing is more conducive to happiness, than fixing on an end to be gained, 
and then steadily pursuing its attainment.

7778. Forming a plan of conduct. Though some things in every man's life, and 
often the most important things, are the result of accident; yet here, as in every other 
where a multitude of actions are to be performed with a view to an ultimate object, a 
plan must be of importance for their arrangement. No man is born in possession of 
the art of living, any more than of the art of gardening. The one requires to be studied 
as well as the other; and a man can no more expect permanent satisfaction from actions 
performed at random, than he can expect a good crop from seeds sown without due re-
gard to soil and season. The greater part of mankind enter on life without any fixed
object in view; or, if they form some general notion of acquiring wealth or distinction, they form no plan by which it is to be accomplished; the consequence is, that such persons, after blundering on through their best years, arrive at the end without having gained anything but experience, now of no use to them. When we look round and observe the quantity of misery in the world; the greater proportion is, or seems to be, the result of a want of plan, or of a bad plan of life. How many parents are unsuccessful in their struggles to maintain a large family; the result of too early marriage, and a thoughtless and unmeasured procreation! How many find themselves arrived at old age, with no other resource for support but charity; the consequence of want of foresight in expenditure! How many are suffering under poverty brought on by their own want of frugality, or positive extravagance; or under disease from excesses and irregularities committed in the hey-day of life! And how many, among those not born to inherit property, who, at no period of their life, have any other alternative between hard labor and deficient food, than disease and want!

7779. Want of plan may not, in every case, be the cause of all this misery; because accident enters into life for something, both in the unfavorable as well as the favorable side of the question; but we have no hesitation in asserting, that want of plan, as a cause of misery, is as ninety-nine to a hundred. Any plan at all, even a bad plan, is better than none; because those who set out on any plan will, in all probability, sooner discover its errors, if a bad one, and correct them, than those, who set out on no plan, will discover the want of one, and form a good plan. — Plan, in short, is predestination, as conduct is fate. The young gardener, who is just setting out in life, may well tremble at the consequences of proceeding on the journey without the guide of a judicious plan. This plan he must form himself: because he alone knows the nature of his talents and resources; — all that we can do is to offer a few hints.

7780. In order to be able to form a plan, it is previously necessary to determine the object to be obtained by it. Happiness is the object of every action of human life, and consists in the gratification of certain wishes, and the avoidance of others. Of these it is peculiar to you, and you are to procure, as much as possible, clothing, food, rest, relaxation, entertainment, &c. It is to be, however, of the earliest, and continue to the latest period of life. All these gratifications are procured by labor; in savage life, by hunting, fishing, and gathering fruits, till the man, no longer able for these labors, is obliged to lie down and die of want; in civilized society they are also obtained by labor; but here, what is called property exists; and man, in the vigor of his days, when the supplies of his labor are greater than the demands of his wants and desires, or when he chooses not to gratify the latter to the full extent admitted by the former, can, as it were, embody a part of his labor to be made use of when he is no longer able to perform it with ease. A man, in this case, is said to arrive at independence; instead of want, as in the case of the savage; or of beggary, as in the case of the improvident.

7781. Independence is the grand object which not only a gardener, but every man destined to live by the exercise of his labor or talents, ought to have in view. At certain periods of life, when the imagination is vivid, and health and spirits in their utmost vigor, some may prefer glory, high literary or professional reputation, or even present pleasure; and it is a noble attribute of our nature to prefer these to mere accumulation of money: but a great warrior, poet, or painter, arriving at old age and want, if the latter be brought on by common improvidence, will not find himself surrounded by many marks of distinction; and, though it may possibly be some consolation to him, that the three or four letters composing his name will be sometimes pronounced together after he is dead, yet it will not be much.

7782. The exercise of his profession is the most rational mode in which a gardener, or any person properly educated to one, can pursue independence. Only extraordinary circumstances can justify a change of profession; in common cases it indicates a want of steadiness of character, or a want of success; and the latter is commonly attributed to want of skill. It is better, therefore, to pursue unremittingly the profession to which we have been educated, even though we should not be very successful in it, than to risk an infringement on character by adopting another. The practice of gardening, as we have already seen (7377.), is carried on by three different classes, serving, tradesmen, and artist gardeners. The greater number of young men cannot do better than commence in the first branch. To begin in the second, unless an established business is purchased, a partnership in a respectable firm procured, or some situation discovered where there is an effectual demand for produce, would, to a young man without connection, be attended with at least a loss of time, if not with greater losses. As to the third branch, the demand is so very limited, that it can never be recommended in a general way. It remains, therefore, for the young gardener to look to the serving branch, as that by which he will the more certainly attain to independence.

7783. Of serving gardeners, there are two species, with their varieties; the public gardener and private gardener. The latter is the only species to be recommended in a general way; but whichever a young gardener adopts, it would be well if he could previously procure himself to be sent abroad for a year or longer, as gardener or collector to some expedition; or even if he could, at his own expense, visit Amsterdam, Antwerp, Leyden, and Paris. All this he may do at present, proceeding by sea to Rotterdam, either from London or Edinburgh, for less than twenty-five pounds; and a judicious young man, even though so much devoted to improvement as we suppose our young gardener to have been, ought to have saved that sum by his twenty-fifth year. In times of war it may be more expensive, or impossible.

7784. Situations. Though it be seldom that a gardener can choose a situation for him-
self, it may be proper to mention, that by far the best in the world are in England; there are some good situations in Scotland, and a few in Ireland; and there are occasionally good offers to go abroad as gardeners to the governors of British colonies, or to eminent merchants there. The principal foreign openings for British gardeners, however, are in Russia, where the emperor employs nearly a dozen head gardeners, generally British; and where the same, or a greater number, are in the service of the first-rate nobility. The salaries given are not very great; but the accommodations and necessary advantages are sufficient to admit a frugal man’s saving the greater part of the salary. Great care is requisite, however, to have a written arrangement before leaving this country, including a permission to return at pleasure, as no confidence can be placed in the verbal agreements of most of even the highest Russian nobility. We know of no other foreign situations worth notice. If a gardener thinks of going to America, or any of the colonies, on his own account, he will, of course, require a certain capital, and must also reckon on spending his days there. Supposing a young gardener to have obtained a tolerably good situation at home, and to have proved it for a year or two, he should, in our opinion, set about two things; the first is saving money, and the second is entering into the married state. The first is absolutely essential to the scheme of being independent in old age; the second nearly equally so to passing through life comfortably.

7785. With respect to saving money, we shall not attempt to state the proportion of neat wages that may be yearly saved; nor how the money may be best laid out; as these depend on circumstances. All we need suggest, is the necessity of keeping the ultimate object, and its great advantages, continually in view, and to prefer security of principal to high interest. As some data to enable the reader to estimate the accumulation of money saved, and put in a savings’ bank, or in the funds, we shall suppose a gardener to begin saving at the age of 27, and to continue saving till he attains his 50th year; laying out every year’s savings at only 4 per cent., adding half-yearly the interest to the principal; and at the end of that period purchasing an annuity for his own life, or the joint lives of himself and wife, with the accumulated sum: then—

7786. By commencing master-gardener, and beginning to save at twenty years of age, a gardener, or even a common laborer, may attain the same advantages as to independence; but with inferior domestic comforts, as he cannot afford to spend so much annually; and with less enjoyment from literary and intellectual sources, because his time for previous improvement is reduced one half; and in the after part of his life, as he will only be able to obtain inferior situations, he must calculate on laboring personally. If he begins at twenty, however, and saves till he is fifty, the additional time will bring his smaller sums to very nearly the same totals as those of the more accomplished gardener: thus—

7787. These calculations being made at the rate of 4 per cent. interest, and the Northampton valuation of life, (by which a man at 50 is estimated to live 18 years longer, while in London only 16 years,) must be considered as low rather than otherwise.

7788. The vulgar reason why a young man ought to save money is, that he may get together as much as may enable him to collect some furniture and get married. This, however, may be called saving to produce want and misery. A young loving couple, anxious to consummate their first wishes, will not be very nice in the quantity or quality of their furniture. All they consider necessary is accordingly often acquired before either are twenty. Housekeeping and propagation are commenced; and thus the foundation laid of a life of hard labor, scanty food, and their attendants, bad temper, and often disease. After twenty-five years of bustle and distraction, half a score of children have been produced, and are most probably growing up in rags and ignorance; and all that this couple can say is that they have struggled hard to create nine times as much misery as that by
which they are themselves oppressed. If the man had limited himself for twenty-five years to making the heads of pins, he might have accumulated as much as would have made him independent and comfortable, and still had sufficient time before him to marry, and enjoy the comfort and solace of a wife and children. But the use of a wife to a gardener, and to every man who is not independent, ought to be chiefly as the operative partner in his domestic establishment; to prepare his food, and keep in order his lodging and clothes. If, in addition to these duties, she has cultivated, or will cultivate her mind so as to become interesting as a companion, so much the better; and if the parties further think that they can attain their object of independence, and rear one or two children, let them do so. Universal sources of happiness should never be rejected, when they can be retained.
KALENDARIAL INDEX.

The almanac time in this calendar is calculated for the meridian of London; but as a kalendar of nature is given for the metropolitan district, the almanac time may, in every part of the empire, be varied to suit the local climate and vegetation.

In general, other circumstances being alike, four days may be allowed for every degree, or every 70 miles north or south of London: in spring, operations may be commenced earlier in that proportion southwards, and later northwards; but in autumn the reverse, and operations deferred as we advance southwards, and accelerated as we proceed to the north. In every case allowing a due weight to local circumstances.

**Remarks.**
A cold January is reckoned seasonable. The gardener, during this month, does not labor in the garden more than five hours a day: allowing one hour more for early and frosty mornings, and eleven hours for sleep, there remains eleven hours for personal improvement. Let the young gardener, who is amiable, of distinguishing himself from the common clay of his profession, not let one of these hours run to waste, 7741.

*In the first week:* shellfish snails (Hélie) and earthworms (Lumbricus terrestris) appear.

*Second week:* red bud (Maculata rubecula) whispers, nuthatch (Sitta europaea) chatters, mistletoe (Turdus viscivorus) sings, and wagtails (Motacilla alba et alia) appear.

*Third week:* the common lark (Alauda arvensis) congregates.

*Fourth week:* snails (Hélie hortensis) and slugs (Limax ater et bidulbans) abound in sheltered parts of gardens; the hedge-sparrow (Motacilla modularis) whispers, the large titmouse (Parus major) sings, and flies appear on windows.

2. Kalender of vegetable nature round London.

*In the first week:* some plants accidentally in flower; and others, as the laurustinus, continued from December.

*Second week:* winter aconite (Eranthis hyemalis), Christmas rose (Helcbrus latifolius) in flower, and hazel (Corylus avellana) catkins beginning to appear; common heath (Lumecmis pericyno- num) buds begin to appear.

*Third week:* primrose (Primula vulgaris) flowers in sheltered places; daisy (Céttia perennis) and chickweed (Chris nigrum) begin to flower.

*Fourth week:* mezeon (Daphne mezereum) begins to flower; and sometimes sperry (Spergula arvensis), pansy (Viola tricolor), white scented violet (Viola odorata), archangel (Lunum rubrum), and colts-foot (Tussilago farfara) show blossoms.

Sow (3071) early frame and Charlton peas about the beginning, and some dwarf marrowroots about the end of the month. (3081.) Early managan and long-pod beans in the first week (3016) and the last. (3017.) In the last fortnight, on a sheltered border, sloping to the south, the hardy green Egyptian, early and brown Dutch lettuces. (3074.) On a similar border, in the first and second week, early dwarf short-topt radish; in the last fortnight, the salmon-colored, (3072.)

*Protect* (3036.) by temporary coverings, newly sown seeds, as lettuce, endive, celery, &c.

*Transplant* (3079.) strong plants of the brassica tribe and parsnips, &c., so as to run for seed.

*Dig* (1841.) and trench (1764.) vacant ground in dry weather.

*Prepare* (170.) composts and manures. Attend to beetroot (3535.), by picking up all dead leaves, and removing all plants killed by the frost, &c. (3555. to 3073.)

**Insects,** &c. (3276.) Destroy slugs, set traps for mice, and remove all larvae, webs, eggs, &c.

4. Hardy fruit department.

*Plant* (3071.) fruit-trees in general, in open weather.

*Protect* (3016.) newly-planted trees from frost and drought by mulching (3565.) fig-trees by fences or mats, if you have neglected this business in October. (4801.)

*Prune* (2110.) apples, pears, plums, cherries, gooseberries, currants, and raspberries, preferring mild weather, or only moderate frosts. Prune first such trees as stand in compartments or borders that you wish to dig or dress (2573.) apricots in the last fortnight, if very mild. (4325.) Loosen the extremities of the shoots of such trees as it is not proper to prune at present, and wash them with soap-suds and sulphur, or scalding water if insects are suspected. (3075.)

*Dig* (1841.) and stir the earth round trees which have been pruned; trench ground intended for trees.

*Stake* newly-planted trees. (3081.)

*Clean* trees from moss, mistletoe, &c. (3024.) Guard against hares, by tarring or lime-whiting their stems, or tying thorns round them. (3022.)

*Destroy* (2580.) insects by washes, or hot water, applied both to walls and trellises, and to the trees.

*Fruit-room and cellar.* (3098.) Look over the fruit in open boxes or shelves, and pick out decayed or tainted ones; but do not touch the casks of fruit in the cellar. (3208.)

5. Culinary hot-house department.

*Glass case without heat.* (3066.) Sow radishes, lettuce, carrots, small-salads (3096.); and peas and beans for transplanting. (3016.)

*Hot-beds and pits.* (3058.) Prepare for making up hot-beds for early cucumbers (3078.) and melons (3081.), if you have not begun in November. Sow early radishes, and small-salading on sight hot-beds. (4078.) Sow carrot on a slight hot-bed, to produce a crop for drawing in April and May. (3040.) Kidney-beans, peas, potatoes (3061. 3001. 3568.), &c. may be sown and planted on sight hot-beds in small pots, to fit them for transplanting. (7445.) Forc or asparagus (3549.), sea-kale (3056.) and tart-rhubarb (3030.), on hot-beds, or in pits, or in the open garden. (3508. and 4083.)

*Pinery.* (3097.) Give air and water sparingly to pines; sow kidneybeans; take in strawberries.

*Forcing-houses.* (3040. and 3003.) Give air and water, and, according to the progress your trees have made, increase your stimului of every description. Attend to kidneybeans and strawberries, wherever you have any store-room. (3057. and 3508.)

6. Flower-garden. — Open ground department.

*Plant* (3077.) dried roots of bolder-flowers, if not
done before; but defer planting bulbs of the finer florists' flowers till February, unless the weather is very mild. (5052.)

Transplant (2078.) daisies, and other edgings, if the weather is fine, and it was not done before. (5629.)

Protect (2036.) choice plants by matting, litter, cases of wicker-work, old bark, and all other proper means, observing to do it with due attention to neatness in this department of gardening. (2359.)

At this period, larger sorts of tulips, which will emerge from the ground by the end of the month; hoop them over, and apply mats. (6529.)

Ranunculuses and anemones, which have been planted in November, will require a similar attention. (6276.)

7. Flower-garden.—Hot-house department.

Glass case without heat. (5686.) Attend to the alpines (6537): they should have air every dry day, and must, in very severe weather, be protected by mats, and even litter, to imitate their native snow covering at this season. Mignomette and other prolonged annuals, as stocks, sweetpeas, &c. will require similar attention. (6486.)

Look to choice auriculae (6735.) and polyanthus (6598:); keep them plunged in frames in old tan, or, what is better, saw dust, or ashes. In general, never attempt to keep a potted plant through the winter in a cold frame, unless it be plunged, or the pots be standing very close together.

Hot-beds and pits. (6218.) Begin to force roses (6218.) and other shrubs, and hardy flowers, as well as bulbs, if you have not begun in November: put bulbs in blowing-glasses. (6245.)

Green-house. (6211.) Minim. temp. for this month, 40 deg., max. at fire-heat, 44 deg. See that the most delicate plants be in the warmest part of the house, in so far as is consistent with other arrangements: give air freely in fine weather, and water at all times sparingly. (6212.)

Dry-stone. (6317.) Min. temp. for this month 45 deg. with fire-heat; water very sparingly, but give air every fine day. (6212.)

Bark, or moist stoe. (6214.) The minimum temperature during this department, with fire-heat, may be 38 deg. and maximum 70 deg.: water and give air with discretion.

8. Pleasure-ground and shrubbery.

Plant (2077.) most sorts of deciduous trees in fine weather, and deciduous hedges. (6585. and 6816.)

Prune (2110.) native and naturalised deciduous shrubs and hedges (2214.); cut deciduous hedges (6590): attend to the weather: only the very hardest natives are to be cut during frosts and snows. (6898.)

Digging. (1519.) Continue this during this month in the interstices of masses and groups, as well as in the shrubberies and other screen plantations. Where the exterior abounds with flowering shrubs and plants, it should have been dug in autumn, and must not be deferred till next month.

Dress turf (6191.) and gravel (1597.): the former may be done in moist, but the latter only in dry weather.

Form and repair lawns and turf verges, in mild weather. (2100. and 2101.)

Lay out (6873.) ground for a nursery, if not done in autumn; gather all manner of tree-seeds. (6892.)

Dig (1561.) and trench (1570.), vacant ground between the rows of plants, which are to stand a year longer: fill up any vacancies as you go along. (7470.)

Lift (2081.) plants fit for planting out.

Prune (2110.) nursery plants before planting: do this in sheds, and keep the roots covered with moss or moss.

Gather (2292.) cones of the larch and other fir, and of the pine tribe. (6884.)

Protect (2406.) beds of germinating seeds with straw or litter; put other tender seedlings in pots under frames, or mats and hoops, from birds, mice, snails, and other vermin. (2290.)

Rolling-ground (6770.): turn over the different layers frequently, and see that none of them are soaked with water.

Seed-lift and cellar (6890.): look to all the sorts of seeds in these departments; whether buried in sand, or in heaps, layers, baskets, drawers, or bags.

Destroy (2250.) vermin, and, in bad weather, cut and paint tallow and prepare parchment labels, number-sticks, hooks for laying, &c. (1317.)

10. Trees.—Permanent plantations and park-scenery.

Prepare (6517.) ground for grove or screen plantations; for useful strips; for detached, and for hedge-row trees; and planting in general. (6878.)

Plant (2126.) in dry weather, deciduous trees, Scotch pine, and larch fr. (6967.)

Prune (2110.) deciduous trees, and also larch and Scotch pine groves (6882.), hedge-row trees, and herbaceous forest-trees in every form. (6854.) cut and plash, repair and renovate, and complete hedges of deciduous plants or trees. (6817.)

Enclose and fence (6820.) ground intended to be planted (6882.) by posts and rails in all weathers (6830:), but by mortar walls, in mild weather only. (6825.)

Felt (6954.) timber-trees, where the bark is no object.

Thin (6955.) crowded plantations, distinguishing between those of sorts fit for hedging, or transplanting, and sorts for consumption in any of the usual forms of young trees, or coppices (6966. and 6915.), and otherwise prepare for planting the more valuable sorts. (6981. and 6915.)

Excavate and renove ground for forming pieces of water, &c. (1945, and 7217.)

FEBRUARY.

REMARKS.

This month (the spring or grand flush month of the Saxons) is usually subject to much rain, or snow; either is account:eligible: the old proverb being, "February cold, and the blackbird white." Early frosts are not unfrequent, and especially cucumbers and peaches, require great care in this month; when the sun does not appear for several days, danger is to be apprehended from dampness, and at other times from chills.

Fourth week: the partridge (Tetrao perdix) begins to pair, the blackbird (Turdus merula) whistles, and the firs and woodlarks (Alauda arvensis et arborescens) sing; the hen (Phasianus colchicus) sits.

Third week: the snowdrop (Galanthus nivalis), and the (Iris versicolor), white dead-nettle (Lathyrus album) and polyanthus (Primula veris) flowers; and the elder (Sambucus nigra), and some roses and honeysuckles, begin to expand their leaves.

Second week: common crowfoot (Ranunculus repens), dandelion (Leontodon taraxacum), and the female flowers of hazel (Corylus avellana) appear.

Third week: veronica agrestis in flower; many of the poplar and willow tribe show their catkins; and
also the yew (Taxus baccata), alder (Alnus communis), the tulip (Tulipa), crown-imperial (Fritillaria imperialis), and various other bulbs, boldly emerging from the ground.

Fourth week: the erica carnea, wood strawberry (Fragaria vesca), some speedwells ( Veronica), the groundsel, and sometimes the stock and wallflower (Cheiranthus), in flower. Some sorts of gooseberries, apricots, and peaches, beginning to open their buds.

Sow (2071) radishes at twice or thrice (5749); round-leaved spinach twice (3771), lettuce for succession (3790), peas and beans in the beginning and end of the month (3501 and 3516); some early cabbages, sowing any plants of the last sort at the beginning and end of the month, red cabbage. (3542 and 3518).

In the last week savoys (3518); in the last fortnight dill, chervil, and fennel (4607 to 4610), early Horseradish root near the end of the month (5718), early Dutch turnip in the last fortnight (6388), small salads every fortnight (4785), onions for a crop in the last week, and a few leeks at the same time. (3815 and 3835).

Temporary coverings. (2906) Cover with litter, fronds of spruce and silver fir, mats, and other means, as circo, as it may be required.

Plant (2077). Jerusalem artichokes (3692), chives, garlic, shallots (3583 to 3584), horse-radish (4115), lettuce (4459), and potatoes. (3476).

Propagate, by rooted offsets (1885), mint, balm, sorrel, penny-royal, tansy, tarragon, fennel, and burnet: (4081 to 4121).

Transplant (3725) for seed, if it was not done in autumn, the brassica tribe, onions, carrots, turnips, beet, celery, endive, parsnips, and leeks.

Digs (34) and trench (34) of a good vacuum ground in moderate weather, and perform all other operations of this kind only in dry weather.

Destroy insects by the usual means. (3583).

Sow potatoes. Look out onions, and other dried roots. (1704 and 1705).

Toad-room. See that tools are always cleaned before being laid by at this season. (1706).

4. Hardy fruit department.

Plant (3071) all sorts of fruit-trees, when the weather is fine (4361); strawberries towards the end of the month. (4717).

Protect roots of new-planted trees by mulching (2089); tops of apricot, plum, peach, and nectarine trees coming into blossom. (2506).

Prune apples (2510). Apricots, peaches, and nectarines, before the blossom-buds are much swell (4880 to 4530); apples and pears before the end of the month, at the end of May (4451), and finish vines (4654. 4670. 4680 and 4686).

Prepare ground for planting (2077); spring-dress straw, trees, and plants; dig and dress ground where the trees are pruned; support newly planted trees with stakes (2085); clear the bark of trees of moss, &c.; fence orchard trees where sheep, cattle, or hares may be expected. (3584).

Destroy insects. (2580).

Fruit-room. (2585). Keep continually examining the house fruit, whether in the open shelves, or cloe drawers: remove all tainted specimens.

Fruit-cellars. (2599). Such fruit as is put up in close casks, and sealed or plastered up to exclude the air, will require more attention than keeping out extreme frosts, so that the temperature may stand between 32 and 40 degrees.

5. Culinary hot-house department.

Glass case without heat. (2936). Sow lettuces, small salads, &c. as in last month (3589), plant potatoes. (3375).

Hot-beds and pits. (5787). In the first week begin to force cucumbers and melons: in general, the beds now set to work produce finer fruit than those put in earlier in the season. (2937). Continue sowings of salads (3589), and kidneybeans (3587); begin or continue to force asparagus, potatoes, scallions, tart-chiliubarb, &c. (4210); sow a few seeds of cabbage and cauliflower plants for early planting.

Mushroom-beds. Protect established beds, and spawn new ones (3434); keep up the heat of all hot-beds by linings. (1976).

Pinery. (5925). Attend to the proper temperature (2947 and 2972): pines want little air or water at this season. See that suckers on dung-heat are not too moist.

Forcing department. (3590). If you have not begun before, this will be very good, to commence with most sorts of fruits, peaches, cherries, vines, &c. Set in strawberries and other plants in pots, also fruit-trees and shrubs, and plant kidneybeans; apply stimulating degrees, last, if not doing well enough, do not decline, otherwise you produce an injurious check to vegetation. See to the stems of vines that are outside the forcing-houses and staves which are at work. (3592 and 3531).

6. Flower-garden.—Open ground department.

Sow (2071). a few hardy annuals in the last fortnight, if the weather be fine: most of the sorts are better deferred till the end of March. (5607). Mignonette and ten-weeks’ stocks, in a warm border, to be propagated in every other. (5584 and 5485).

Propagate hardy plants from the root and herb; but September or March are better seasons. (4903). Plant earthed roots, when the weather is open and dry. (5601).

Transplant (2079), if the last fortnight be fit weather, the hardier biennials and perennial border-flowers. (3493 and 3625).

Shelter and protect (2936) by all the usual means; but take care not to exclude air and light a moment longer than is absolutely necessary.

Prepare vacant ground for plants and trees, also composts for plants in pots. (3518).

Bees. Feed such hives as are weak. (1748).

7. Flower garden. — Hot-house department.

Glass case without heat. (2936). Dress select auri- culas, and cover them at night to promote their growth (5767); sow ten-weeks’ stocks, and mignonette, for sucrional supply. (3592 and 3586).

Hot-beds and pits. (3578). In the last week, prepare for tender annuals, continue to force bulbs, and the usual sorts of border-flowers, and Dutch roots in dung-beds and pots heated by fermentable substances, steam, or by smoke-flues. (6503).

Green-house. (6211). Minimum heat for this month, 40 deg., maximum, with fire-heat, 44 deg. Give air freely in fine weather, but water sparingly; the alternate drying by fire-heat, and then mace- rating by watering, is a sure way of killing tender plants in small pots.

Bar, or moist stone. (6214). Give air whenever the thermometer rises to 70 deg. or under it, if the sun shines upon it for 2 hours and 30 minutes. Begin to propagate by the usual modes; attend to neatness and routine culture.

8. Pleasure-ground and shrubbery.

Plant (3077). deciduous trees and hedges, as in January: deciduous shrubs after the middle of the month. (6128. 6160 and 6189).

Prune (2110) as before, finishing most sorts by the middle of the month, if possible. (5610).

Dig (1854) as before, and include the flower and shrubbery borders towards the end of the month. Sweep and roll gravel-walks and lawns (5619); trim the edges of verges with a weeding-iron; remove all weeds and rubbish. (2921).

Form and prepare lawns and gravel-walks, as directed for last month. (2100 and 2101).

Fruit-trees. Sow kernels and fruit-stones. (7011 and 7016); lay quinces, walnut, and mulberry trees; plant cuttings of the gooseberry, currant, and elder. Lay or graft the berberry, hazel-nut, and bilbert. (7031). Preserve cuttings of the vine and fig in dry earth (4585); plant suckers of the raspberry, (3582) for grafting. (3583).

Ornamental shrubs. Sow hardy deciduous sorts; lay and plant cuttings, and take off suckers for propagating; plant out in nursery rows, and prune deciduous sorts. (7031).

Forest trees. (6982 to 7011). Sow mountain ash, hornbeam, wild cherry, hawthorn, ash-keys, hazel-nut, acorns, walnuts, Spanish and horse chestnuts, &c.
KALENDARIAL
and bore-the according weed. The the the 0-716
saxifraga daphne nigral, (Rosmarinus cock
Drum-headed (Columbi) winter
crop. for (4079.) (.3492.)
(4003.), old store onions, as scallions or small bulbs for a full crop of large bulbs. Jerusalem artichokes and sea-kale, and in the last fortnight, potatoes for a full crop. (3576.)
Temperature of Average coverings (2236.) : continue these as in last month.
Propagate edible peripherals by slips and offsets (1888, and 1908.)
Transplant the brassica tribe, lettuce, and asparagus. Fill up vacances. (2496.)
Dig, &c. as in last month (1864.) from comports and earth. (3075.) Store rooms. (2890.)
Storeroom. Remove, delaying articles, and admit plenty of air, &c. (1704. and 1705.)

In the first week: the ring-dove (Columba palama-
bas) coos, the white wagtal (Motacilla alba) sings, and the yellow wagtail (Motacilla flava) appears, the turtur turdus, and the small (Helie), and slug (Limace), engennderer.
Second week: the jackdaw (Corvus monedula) be-
gins to come to churches; the tomtit (Pyrrus car-
neolus) has its spring note; brood wood-owls (Strix nilua) hoot; and the small tortoise-shell butterfly (Papilio urticae, L) appears.
Third week: the marsh titmouse (Parus palustris) begins his notes; various flies (Musca) appear, the fox (Canis vulpis) smells rank; the turkey-
cock (Meleagris gallo-pavo) struts and gobbles.
Fourth week: the yellowhammer (Emberiza citriela) and green woodpecker (Picus viridis) sing; rooks, ravens (Corvus), and house-pigeons (Columba) build; the goldfinch (Fringilla carduelis) sings, field-cricketts (Scarcabceus) open their holes; and the common flea (Pulice trivittata) appears.

2. Kalendar of vegetable nature round London.

In the first week: various species of the pine, larch, and fir trees in full flower; the rosemary (Rosmarinus officinalis), the willow (Salix), and bay (Laurus nobilis), in blossom; various trees and shrubs beginning to open their buds.
Second week: the common honeysuckle (Lonicera periclymenum) and some roses in leaf; crocus ver-
bus, and other sub-species, and some scilles, in flower; holly (Ilex aquifolium) and common broom (Ranunculus repens), hepatica and elder (Sambucus nigra), sometimes in leaf.
Third week: saxifraga oppositifolia, draba verna, daphne pontics and collins, and lonicera nigra, in flower.
Fourth week: the peach and nectarine, apricot, cherry (Prunus japonica), pyrus japonica, crown-imperial, saxifraga crassifolia, buxus sempervirens, and other plants in warm situations in flower, or just ad-
vanishing to that state.3. Kitchen-garden.

Culinary vegetables.

Sow (371.) the main crops of most esculent. Drum-headed and Scotch cabbages for field-culture. (347.) Peas (361.), beans (351.), lettuce (3690.), spinach (371.), and small salals every fortnight. (4079.) Indian cress (4119.), a few savoys (3519.) for an early crop; and towards the end for a full crop (3618.) for a full crop; and beets (3835.), some red and white cabbage (3492. and 3512.), full crops of carrots (3718.) and parsnips. (3727.) Asparagus. In the third week (3862.) Cauliflower in the last fortnight, for a full crop (3548.); borc.
coles (3592.), and Brussels sprouts for autumn and winter crops. (3584.) In the last fortnight, sea-
kae (Cauliflower, cabbages (3835.), turnips (4289.) colery (4003.), alsaiders (3954.), and most culinary ar-
matics, as parley, dill, fennel, &c. (3081.) In the last week, summer savoys (3519.), and mustard for seed. (4057.)

MARCH.

<td>The beginning of March usually concludes the winter; and the end of the month is generally indicative of the succeeding season: it sometimes comes in like a lion, and goes out like a lamb. The Saxons called this month &quot;the lengthening of the day,&quot; and hence its name, from the increasing of the days. The most laborious period of the gardener's year is the last half of this month; and the first fortnight of April.</td>

Plant (3717.), in the first fortnight, horse-radish (4114.), licorice (4245), chives, shallots, and gar-
ic (3810.), as old store onions, as scallions or small bulbs for a full crop of large bulbs. Jerusalem artichokes and sea-kale, and in the last fortnight, potatoes for a full crop. (3576.)
Temperature of Average coverings (2236.): continue these as in last month.
Propagate edible peripherals by slips and offsets (1888, and 1908.)
Transplant the brassica tribe, lettuce, and asparagus. Fill up vacances. (2496.)
Dig, &c. as in last month (1864.) from comports and earth. (3075.) Store rooms. (2890.)
Storeroom. Remove, delaying articles, and admit plenty of air, &c. (1704. and 1705.)

4. Hardy fruit department.

Plant (3717.) fruit-trees in general. The fig (4831) and mulberry may now be planted. (467.) Finish prunings and tying-trees; dig before the middle of the month, and currants and raspberries by the end. (4642. 4670. and 4696.) Alpine and wood straw-
berries may be planted, though autumn is preferable. (4717.)
Protect roots by mulching (2068.), and trees coming into blossom by the usual means.
Prune (3110.) till the middle of the month; but finish as the season permits. If not, apricots may be pruned till the 5th (4352.), peaches and nectarines till the 15th (4485.), gooseberries to the 7th, red and white currants to the 10th or 12th, and the black currant to the 20th. (4646. and 4675.)
Dig and dress between rows of currant-trees, and other fruit-trees, where this operation has not been done before. Dress any strawberry beds you have not been able to do before. (4718.)
Destroy insects. (2890.)
Fruit-room. (2528.) Examine the fruit in the room; take care not to leave open the door of the cellar so as to raise its temperature above 40 degrees.5. Culinary hot-house department. Glass case without heat. Sow kidneybeans to receive a few weeks' protection. Remove frames from cauliflower-plants. (3545.)
Hot-beds and pits. (5978.) Go on with hot-beds for cucumbers, melons, &c. (3164.) Sow a few turnips on a gentle hot-bed to come in early. (3390.) Sow all sorts of culinary annuals. Give air and apply linings to maintain the proper temperatures. (1976.) Attend to pine suckers and crowns; shift any that may require large pots, and examine the roots of such as are sickly. (3718.)
Pine-house. (3075.) Keep sowing kidneybeans, and filling spare corners with strawberry-pots for succession. See that your bark-pit be in proper heat, and attend to the temperature for this month, and the other varieties of culture. Pines are now generally shifted. (3018.)
Forcing department. (2549.) Attend to the cul-
ture of the melons in the particular kind, and generally to keep down insects by watering; promote setting of fruit by air, and encourage growth by steaming or filling the house with vapors by powerful fires and water-
ings over the leaves and every part of the house.
6. Flower-garden. — Open garden department.

Sow (2917.) hardy annuals (6507.), in the second, third, and last week; and some of the more robust half-hardy annuals about the end of the month. (6513.) Such hardy annuals as their flowers, for vases, deserve the place of honor, scabious, bastard rocket, sweet alysson, clary, Chinese hollyhock, and Indian pink. (6565.) Biennials in general, and also perennials towards the end of the month. (6452.)

Propagate by rooted slips and offsets; but next month is preferable for rootless slips and cuttings. (2807.)

Plants dried roots; finish with the anemone and ranunculus in the first fortnight. (6256. and 6875.) Transplant annuals from the patches in the borders, and biennials and perennials from the flower-garden nursery, into their final sites. (6110.)

Shelter choice border and all florists' flowers in severe weather. (2282.) Dig trees, hedges, &c., &c. only in dry weather. Clean up all borders, and prepare vacant ground. (1854. to 1881.)

Bees. Feed weak hives as in last month. (1748.)

7. Flower garden. — Hot-house department.

Glass case without heat. (2986.) Take care of alpines and prolonged annuals, remove all weeds, and keep the house free from all cover. Cover auricula-frames in very severe nights (6575.) by keeping them rather warm at this season they will come up with fine stalks to support their magnificence. (6752.) Sow half-hardy annuals for transplanting, they will come into flower as soon as those sown in the open air last month. (6513.) Take care of the early sowings. (6578.)

Hot-beds and pits. (2978.) In the first fortnight sow half-hardy annuals on a slight hot-bed for transplanting to come in first. (6513.) Sow tender annuals at any period of the month. (6575.) Plant tubercoses in pots for forcing. (6535.) Force roses and other flowering or odoriferous shrubs and all desirable hardy flowers in pots. Sow seeds of greenhouse and hot-house plants to be propagated in this way. Plant cuttings for the same end. (6063.)

Green-house. (6211.) Make no fires unless the thermometer, in the open air, falls to 55 deg.; 45 deg. with fire-heat will be a good medium heat in this month. Begin to propagate by cuttings. (6507.)

Dry-stone. (6716.) A good medium heat for this month will be 55 deg. which may be kept up with very little fire-heat. Give water moderately, but see that you do give wets the earth, and does not escape between the ball and the edge of the pot. Give air freely in fine weather.

Bark, or moist stone. (6214.) Give air in general, and particularly in the summer, when you wish to produce a vigorous growth, shift your plants into a rich compost, water over the top about three o'clock, and then shut the house close up for the night. Do not water when the temperature has been up to 80 deg. (2205.)

8. Pleasure-ground and shrubbery.

Plant (2977.) deciduous trees and shrubs, also deciduous hedges; finish as early as possible, unless the season be unusually backward. Evergreens of the hardier sorts towards the end of the month. (6541. and 6752.)

Prune (2110.) deciduous trees and cut hedges, and finish this work as early as possible. In pruning plants, where the chief object is the flowers, attend to the mode of heading these. In short, never begin to cut a tree before having a clear and distinct idea of what you wish to attain— is it height, strength, leaves, flowers, or fruit?-and prune accordingly.

Dress winter and autumn dung shrubberies. Mulch, stake, water, and attend to neatness. (2529.) Dress and roll turf and gravel; attend to the margins with tartaniser. (1317.)

Form and repair gravel-walks. In some situations imitation gravel-walks require to be turned every two or three years and partly renewed. (1980.)

Fruit-trees. Sow kernels for stocks; lay the vine and the linden, and 4848.; plant cuttings and eyes of the vine in the open air, or in pots, to be placed in a moist heat. Grant towards the middle of the month, or sooner or later, according to the size. Plant out seedlings in nursery rows. (7061.)

Head down newly budded and gratted trees not intended to be removed. (2389.)

Head down trees and shrubs. Sow seeds of the hardier sorts. Evergreens may be sown in the last week. Finish laying decided kinds, plant cuttings and suckers, and grant some of such sorts towards the end of the month. (6752.) Plant out layers, cuttings, and suckers in nursery rows. (7061.)

Forest trees. (6962.) Sow nuts, keys, and berries, and also the seeds of the last year's crops; and begin to sow evergreens. Plant cuttings, suckers, &c. as in February. Plant out from the seed-bed or cutting-border in nursery lines. Dig between the rows of trees and shrubs not intended to be removed this season.

Wood, hedges, &c., &c. Prune, dress, and ramify the surface in fine weather. Dig between nursery lines, where the plants are not to be removed. (6826. to 7061.)

Shelter and protect trees from cold, birds, and vermin. (2066. and 2529.)

Plant all sorts of deciduous trees and shrubs, the Scotch pine and larch trees. (5853.) Towards the end plant most sorts of evergreens. (6572.) Hedges of evergreens. Fill up blanks in plantations of two or more years' standing.

Head down trees intended to stope for underground, or produce single leaders for timber-trees or poles. (6829. and 6894.)

Felt and thin trees and cope; but the barking sorts not till the end of the month, when they will part with the bark. (6041.)

Sow forests and woodlots; about the middle of the month with the smell (Hymenoxus rustica) the vermin will be less likely to annoy the seeds, having the farmer's progeny to attack. (5858.)

Operations on ground, and masonry, may now go on with the most advantage. (6526.)

a. In the month of April, having attained a sufficient length, and the weather being generally dry: external brick walls for gardens, however, are better deferred till May, when all danger from frost will be over.

APRIL

REMARKS.

The weather of this month is distinguished by the rapidity of its changes. It is generally stormy, interspersed with gleams of sunshine, hail, snow, some frost, and occasional showers, which make the deciduous and halchard plants require protection and particular attention during this month. The young gardener, while at work, may study the germination and foliage of trees, and the paleity and delicacy of newly expanded foliage.

Third week; the crested wren (Mecocitta regulus) sings; the blackbird (Turdus merula), raven (Corvus corax), pheasant (Phasianus colchicus), hen (Phasianus colchicus gallus), and duck (Anas bosca) sit; various insects appear; and the feldfare (Turdus pilaris) is still here. Foul weather. When the swallow (Hirundo rustica) returns; the nightingale (Mecocitta luscinia) sings; the bittern (Ardea rutilaria) makes a noise; the house-martin (Hirundo rustica) appears; the blackcap (Machuca nectanegra) whistles, and the common snipe (Coluber natrix) appears.

1. Calendar of animated nature round London.

In the first week: the viper (Coluber berus) and woodhouse (Onicus asellus) appear; the mistletoe-thrush (Turdus viscivorus) pairs; frogs (Rana) croak and breed and spawn, and muskrats (Phalena) appear.

Second week: the stone curlew (Grardarius albicristatus) clamous; young frogs (Rana temporaria) appear; the peacock (Phasianus) row; the trout (Salmo trutta) rise; and spiders (Aranea) abound.
2. Kalenderial vegetable nature round London.

In the first week: the daffodil (Narcissus pseudo-narcissus), the garden-hyacinth (Hyacinthus orientalis), the wallflower (Cheiranthus cheiri), the cowslip (Primula veris), the sweet rocket (Hesperis matronalis), the cow parsley (Anthriscus sylvestris), and various other herbs and trees in flower.

Second week: the ground-ivy (Glecoma hederacea), gentianella (Gentiana acaulis), pulmonaria virginica, the auricula, lilies sempervirens, cynoglossum osmophalloides, and most of the common fruit-trees, and fruit-shrubs in flower.

Third week: some robinia, andromeda, kalanie, and other American shrubs; daphne laureola, ulmus campestris, chrysosplenium oppositifolium, mercia of the S. and U. sorts, and other plant, in flower.

Fourth week: the beech (Fagus) and elm (Ulmus) in flower; ivy-berries drop from the racemes; the larch in leaf, and the tulip and some white narcissi and frullarias in flower.

Sow seed: for a full breadth; lettuce, small salads, peas, beans, potatoes, and the like. Sow peas and beans (3901. and 3617.), broccoli thrice (3555.), borecoles in the first week (3529.), cabbages and savoy twice (3602. and 3519.), turnips twice (3698.), silver-skinned onions every three weeks during summer for drawing; onions, leeks, and cardoons, in the first week, for a general purpose, in (3571.), 7th, for a general crop (4063.), mustard for seed (4577.), carrots, in the second or third week, for a main crop (3717.), kidney beans, in the second week, for a general purpose, in (3407.), parsnips, in the last week of the 1st month (3634.), asparagus and parsnips, in the first or second week, but not later (3577.); red beets, in the third week, for a full crop, and also nasturtiums, salsify, scorzonera, etc. (3740.); Sow the areál, aromatics, and herbs, if not done in March. (4131.)

Propagate by bulbs and dried roots. (1587.) Finish planting the main crops of potatoes. (3600.)

Put in perennial culinary plants by slips and offsets, as all the pot-herbs, aromatics, &c. (1588.)

Transplant lettuce, cabbages, seakale, celery, and cauliflower. (1578.)

Dress artichoke and asparagus beds, or compartments. (3925. and 3584.) Hoe and thinning, onions, turnips; earth up cauliflowers and cabbages, seakale for winter, peas, beans, and potatoes, turnip, beet, tie up lettuce, destroy weeds, and stir the ground in fine weather. (2591.)

Attend to insects, and to the store-room, (2580. and 2690.)

4. Hardy fruit department.

Plant cherries, plums, apples, and pears, till the last week. Pot plums, prunes, and pears, if necessary, to 15th; but defer till autumn what you cannot accomplish by this period, unless the season is unusually backward. (2577.)

Prune, if you have delayed it; but expect vines to bleed, and stone-fruits in general to be much injured by the operation, if not performed very early in the month, and even that is too late. In the last days of the month, rub off the buds of vines which appear where you do not wish shoots. (4259.)

Routine culture. Water, mulch, stake, and fence. Weed strawberry-beds, and pinch off runners, where you do not wish to have young plants. (2077.)

Dust with ashes, especially apple wood, which will begin to appear on forward peach-trees; pick off caterpillars. (2580.)

Fruit—collar. Attend to the temperature, and never break even a cask till you are in want of its contents. (2929.)

5. Culinary hot-house department.

Glass case without artificial heat. If the season is backward, sow in the first week kidneybeans, to be protected till the weather is mild. (2296.)

Hot-beds. Continue preparing a succession of beds for raising and setting out cucumbers and melons. Sow, transplant, shift, &c. all esculents, or pot-herbs, which are tender annually, as gourd, basil, love-apple, capsicum. Maintain the proper degrees of heat by linings. See to pine-suckers. Plant crowns and suckers taken off in the winter. (2712. to 2717.)

Piney. Attend to routine culture: shift the plants, the bottom heat, water and give air as judgment founded on experience, reflection, and vigilant attention shall direct. The pine is a difficult plant to kill, but it requires constant and powerful heat, and rich loam and water more abundantly than is often given to it, to produce large, well flavored fruit; attend to minor articles or forced in the piney, such as vines, fruit-trees in pots, cucumbers, kidneybeans, and strawberries. (3538.)

6. Flower-garden. — Open ground department.

Sow annually: all the sorts for a main crop, or for a succession, if you have sown them in March (6507.); half-hardy annuals in warm borders there to remain. (6512.) Biennials and perennials should be sown as early in the month as possible.

Propagate by rooted and unrooted slips and offsets. (6588.)

Transplant all sorts from the nursery to the borders (2075.); tender and half-hardy annually from the hot-beds to the borders. (5605.)

Routine culture. Weed, hoe, rake, turn the surface, remove decayed leaves, and make the beds as smooth as the plants have done flowering, unless you select a walk or two occasionally for seed. Never leave all the flower-stems for this purpose, and seldom all the pods and seed vessels which are on a stem, as that would weaken the plants.

Protect your auriculas from the extremes of every description of weather: if placed on a stage facing the north, or set on a shaded paved platform abore three feet high, they will be better than if buried in the frames. (6583. and 6584.)

Distribute bulbs, and especially tock the grubs from the leaves of rose-trees: if you do not attend to this, you will have no blow worth looking at. (2580.)

7. Flower-garden. — Hot-house department.

Glass case without artificial heat. Alpines may now be entirely uncovered, and also prolonged annually, and most half-hardy sorts; a few half-hardy annuals may still be sown, if not done in proper season. (6513.)

Hot-beds and pits. Shift frequently such tender annuals as you mean to come to a handsome size, more especially balsams. (6481.) Sow more seed, if you have not enough of plants; plant out some in the borders, but not too soon; there are especially balsams and combs in very warm situations. Plant tuberose roots, and shift those which are coming forward, if they appear to be stinted in their growth. (6582.)

The last month of cutting from either of the following departments (6683.):

Green-house. Fire-heat may generally be dispensed with in this month. Go on propagating by all the methods in use; this is the finest season of the year: a good deal depends on taking off, making, and putting in the cuttings, but nothing will answer, if constant attention is not paid to keeping them in the same degree as to air, heat, and moisture afterwards. (6634.)

Dry-stone. No fire will here be necessary, excepting when the thermometer in the open air is under 40 deg. or 42 deg. Propagate by the usual means, which in general for succulents is cuttings; attend to bulbs now coming into flower. (6694. and 6695.)

Dark cherry, apricot, and store. Go on, as usual, in the store, shifting, propagating, and stimulating as the nature of the different hot-house plants requires, and as your views or duties incalculate; never forget neatness, and have your store of dust, insects, &c. polished. (6716.)

8. Pleasure-ground and shrubbery.

Plant (2577.) such sorts of deciduous shrubs as you deemed too tender to plant last month; but finish this work in the first week. Plant a few roses as late as you can, in order to retard their coming into bloom: (6330.) or, if you can afford the time and expense, place potted roses in the ice-cold cellar in autumn, and do not take them out till the August following, by this means you will have a fine show in October.
and November (6554) Evergreens, the hardiest sorts at the beginning, and the less so at the end of the month. (6572), and some such deciduous shrubs as you have neglected last month; evergreens from the middle to the end of the month. (6884).

Form and repair lawns, by procuring and laying turf, and sowing grassseeds. This is designed to destroy moss on extensive lawns, flood sheep till it be trod down and killed by pressure and manual labor, and lawns, roll. In shady, damp situations, however, moss makes a better lawn than grass, and it should be encouraged by forming the surface of lawns of bog earth in all situations where grass do not thrive, as in town, under close trees. Mow established lawns twice a month; attend to gravel and margins. (6191).

Fruit-trees. (4351). Finish sowing kernels for stocks, or new varieties. Plant cuttings of the vine, fig, gooseberry, and currant, if it has been unavoidably delayed till this unfavorable season. Graft the pear, plum, and apple. (2015). Attend to newly grafted trees, and repair cracks in the clay, or renew such balls as may have dropped off; eradicate all suckers, and pinch off shoots that protrude below the root.

Ornamental trees and shrubs. Finish sowing deciduous sorts, as early as possible. Sow cedars, cy- presses, and other ornamental evergreens about the end of the month. Sow in pots or boxes, or in shady borders of soft peat earth. Transplant evergreens. (6882, to 7057).

Forest trees. Finish sowing common tree-seeds, and commence with the resinous tribe, the larches, fir, and pines; the cypresses, arbor-vitae, &c.

Finish planting deciduous trees in nursery rows, as early as possible. Evergreens may be transplanted during the month. Broadcast the seeds of the cedar and fir tribe, but not of the pine tribe: and get the seeds out in time for sowing the end of this month or beginning of next. (6984).

Sow for forests and woods, and all sorts of profit- able plantations in masses. Observe it is rather late for nuts, and keys, but this is the proper season for small seeds. (7015).

Plant evergreen trees, as pine, fir, cedar of Lebanon, holly, and yew during the month; but finish planting deciduous sorts as early as possible. (7047). Wherever the plants are to be, or have been long out of ground, take good care to dry up their roots, by exposing them as much as you can to the sun and air; do not be nice in planting.

Routine culture. Begin to hoe and clean the ground in plantations, which have been made on prepared ground. Crop the ground in newly made plantations, where cropping is intended.

Operations on ground or rocks may now be pro- ceeded to vigorously. This is the last month of the best months for building. Road-making, draining, encasing, &c. are advantageously performed during this and the two preceding months. But improvements can only be well designed and executed this month, as the trees are covered with leaves, and the ground's sur- face and qualities disguised by luxuriant herbaceous vegetation.

MAY.

Air Temperature

<table>
<thead>
<tr>
<th>Weather</th>
<th>Average of the Thermometer.</th>

London | 56 61 | 2 5 | 30 02 | 0-794 inch. |
Edinburgh | 50 4 | | 29 05 | 1-34 |
Dublin | 62 153 | | 30 04 | 1-14 |

REMARKS. Vegetation now goes on with great vigor, though there are often very cold and even frozen nights, which mainly injure exotics, natives of the warmer climates, such as the potato, dollia, kidney-bean, &c. The human ani- mal, in common with most others indigenous to our cli- mate, is usually in high spirits and vigorous during this month. Woe to the young gardener who exhausts his spirits in any other way than in self-improvement.

In the first week : the titlark (Alauda pratensis) sings; the cuckoo (Cuculus canorus) is heard; the gudgeon (Cyprinus goio) spawns; the redstart (Muscicapa phoenicurus), swift (Hirundo apus), white-throat (Motacilla alba), and stinging-fly (Conopidae) appears.

Second week : the turtle-dove (Columba turtur) comes, the white ant (Formica rufa), the laughing wren (Motacilla curruca), the common flesh-fly (Musca domestica), the lady-cow (Coccinella bipunctata), grasshopper-lark (Alauda leucota echo), and willow-wren (Motacilla aliocata) appear.

Third week : the blue flesh-fly (Musca vomitoria, var.) appears; black snails (Helix aspersa) abound; and the large bat appears.

Fourth week : the great white cabbage-butterfly (Papilio brassicae) and dragon-fly (Libellula trium- lata) appear; the glow-worm shines; and the fern-owl, or goat-sucker (Caprimulgus europaeus), returns.

2. Kalender of vegetable nature round London.

In the first week : geum urbanum, artemisia com- pestris, lily of the valley (Convallaria majalis), water-violet (Hottonia palustris), tulip-tree (Lillio- den tridumiflorum), and numerous other plants, in flowers.

Second week : the oak, ash, sweet chestnut (Fagus castanea), hawthorn (Sorbus aucuparia), the common maple (Acer campestre), horse-chestnut (Aesculus hippocastanum), barberry (Berberis vulgaris), and the ajuga repta in flower.

Third week : the water scorpion-grass, or forget- me-not (Myosotis scorpioides), water-lily (Trillium), milk-wort (Polygala vulgaris), nightshade (Atropa belladonna), and various American shrubs, in flower; and the scotch hyacinthum in the ear.

Fourth week : oaks, ashes, and beeches now generally in leaf, and the mulberry (Morus nigra) begin- ning to open its buds; the cinnamon-rose and

some other hardy roses in flower; and also the bramble (Rubus fruticosus), moneywort (Lysimachia nummularia), columbine (Aquilegia vulgaris), and various other trees and shrubs, in blossom.

Kitchen-Garden. — Culinary vegetables.

Sow hardy aromatic herbs, if not done last month. Small sallad of the time of the month for a complete succession. Radishes and lettuce three times (3970, and 3970). Pea and beans once a-week (3960). Spinage once a-fortnight. (5771). Carrots, for late drawing, twice in the second week. (5718). Summer vegetables in the first week, for a second main crop. (5329). Dwarf kidney- beans, in the first week, for a full crop in July; in the last fortnight, for crops in August and September. (3992). Borrocle and Brussel sprouts for the last crop, and German greens to come in for spring. Savoy for the last crop. (3519). Onions for drawing, young leaks to be late transplanted, cauliflowers in the second and third weeks for a Michaelmas crop. (3542). The less hardy aromatic herbs, and pumpkins, the last fortnight. (4572). Cucumbers for picklers on a dry warm border, in the last week. (4876).

Protection. Continue this, nightly, for kidney- beans and tender plants transplanted from hot-beds. (3506).

Propagate by bulbs and dried roots. If abundance of potatoes have not been planted, effect this as early as possible, in late positions where they may be planted till the middle of June. (3576).

Plant slips and offsets. Transplant the brassica tribe, lettuce, celery, radishes, and other plants for seed, (3970).

Routine culture. Stick peas, top early crops of beans, and also of peas; earth up cabbages, beans, 1499, potatoes, and hoe, and stir the surface among seedlings. Water in dry weather, support stems, pinch off all decayed leaves, &c.

Destroy insects and vermin. (2580).

4. Hardy fruit department.

Plant strawberries, if it has not been done last month. (4717).
KALENDARIAL INDEX.

Prune what trees you have neglected, and run the risk of losing, or leave them unpruned till autumn as a proof of vigilance and skill. (2360.) Summer prune vines, peaches, and other early shooting trees against walls, and such gooseberries and currants, where there to produce early fruit. (2292.) Remove all suckers, excepting selected ones of raspberries, and pinch off strawberry runners as directed for last month. (4717.)

Routine culture. Mulch-beds. (86.) Where necessary. Water strawberries over the herbage, and especially after the fruit is set. (4717.) Destroy insects, especially snails and caterpillars. On the first symptoms of the leaves rolling up, roll them and pick out the grub before it does further mischief. Take special care it does not get at the petals of apple and pear blossoms. (2292.)

Fruit-room. Close a few casks of such desert apples and pears as are now wanted for the table. Close them as soon as you have taken out the proper quantity, and let them still remain in the cellar. (2292, and 2299.)

5. Culinary hot-house department.

Glass case without artificial heat. These will now be chiefly employed with annuals in pots, for prolongation and in striking from cuttings, &c. (3663.)

Glass case without. Go to the directors last month with your tender plants. Plant a few tuberous for succession. (6233.) Attend to cuttings and seedlings from the hot-house and green-house departments.

Green-house. Give abundance of air every day, and in mild nights leave some all night; water over the top, and shut the house in the afternoon when you wish to encourage growth wonderfully. Propagate as before. Shift most of the plants, examine their roots. (2292.) Give abundance of air. Fires will not now be wanted. Look to bulbs, as soon as they have done flowering. Shift all such as require it, putting them into larger or smaller pots, according to their kind, and size of object.

Park, or moist stove. (6214.) Give abundance of heat, air, and water, if you wish the plants to grow and flower vigorously. (6638, to 6716.)

6. Pleasure-ground and shrubbery.

Plant deciduous trees and shrubs, but only to fill up a vacancy, or to cause a check for the purposes of pruning and to promote the operation, mulch, shade, and water. (2079.) Evergreens, especially the more tender sorts, but finish by midsummer of the month. (2079.) Prune (2116.) evergreens, finishing by the middle of the month. (6697.)

Routine culture. Hoe, rake, weed, water, shade, shelter, &c. as circumstances require. Rake and mow once a-week. If showers are frequent, but once a fortnight will do in dry weather. Lay down turf, if not completed before, water well and roll regularly afterwards. (2101.)

Gravel-walks may still be formed and repaired, but the work should have been completed last month. Roll well with a heavy roller. (1956. to 1968.)

Fruit-trees. (4361.) Look over grafted trees. Ornamental trees and shrubs. Sow the seeds of evergreens and American sorts, in the first and second weeks of the month. Lay and graft the tender sorts of evergreens and Americans. Plant out tender evergreens, and Americans, in nursery rows, or in pots, for more convenient removal. (6692.)

Forest trees. Finish planting out evergreens, seedlings, and nurseries as early as possible. Sow poplar and willow seeds as soon as possible. (2292.) These seeds will not come up if kept a very few days out of the ground. (7024.)

Protect from all sorts of garden enemies, and attend to the trained neatness. (2266. and 2556.)

Planting evergreens may still go on, if the weather is as it has been, but the sooner it is finished the better. (6697.)

Pruning. Sing recommends this as a good season for pruning of ashes only, because the wound heals quicker while the sap is flowing.

Felt oak woods and coppices, and other barking trees, but complete the operation about the middle of the month. (6691.)

Routine culture. Attend to planted ground under, or to be put under, light culinary crops. (7037.)

Prepare ground for autumnal planting or forming of plantations by sowing, as the free-seeds ripen. (7817.)

Operate on ground for water, or other territorial improvements. Continue to build and execute plans determined on at an earlier season.

JUNE.

Store-room. Lay up crocus and other bulbs and roots will wanted in the autumn.

7. Flower-garden. — Hot-house department.

Glass case without artificial heat. These will now be chiefly employed with annuals in pots, for prolongation and in striking from cuttings, &c. (3663.)

Routine culture. Mulch-beds. (86.) Where necessary. Water strawberries over the herbage, and especially after the fruit is set. (4717.) Destroy insects, especially snails and caterpillars. On the first symptoms of the leaves rolling up, roll them and pick out the grub before it does further mischief. Take special care it does not get at the petals of apple and pear blossoms. (2292.)

Fruit-room. Close a few casks of such desert apples and pears as are now wanted for the table. Close them as soon as you have taken out the proper quantity, and let them still remain in the cellar. (2292, and 2299.)

5. Culinary hot-house department.

Glass case without artificial heat. Remove glasses from cauliflowers and kidney-beans, according to your necessities. (2298.)

Hot-beds. Go on with hot-beds for frames for melons, and build dumb frames for greenhouse mulching the operation, mulch, shade, and water. (2079.) Evergreens, especially the more tender sorts, but finish by midsummer of the month. (2079.) Prune (2116.) evergreens, finishing by the middle of the month. (6697.)

Routine culture. Hoe, rake, weed, water, shade, shelter, &c. as circumstances require. Rake and mow once a-week. If showers are frequent, but once a fortnight will do in dry weather. Lay down turf, if not completed before, water well and roll regularly afterwards. (2101.)

Gravel-walks may still be formed and repaired, but the work should have been completed last month. Roll well with a heavy roller. (1956. to 1968.)

Fruit-trees. (4361.) Look over grafted trees. Ornamental trees and shrubs. Sow the seeds of evergreens and American sorts, in the first and second weeks of the month. Lay and graft the tender sorts of evergreens and Americans. Plant out tender evergreens, and Americans, in nursery rows, or in pots, for more convenient removal. (6692.)

Forest trees. Finish planting out evergreens, seedlings, and nurseries as early as possible. Sow poplar and willow seeds as soon as possible. (2292.) These seeds will not come up if kept a very few days out of the ground. (7024.)

Protect from all sorts of garden enemies, and attend to the trained neatness. (2266. and 2556.)

Planting evergreens may still go on, if the weather is as it has been, but the sooner it is finished the better. (6697.)

Pruning. Sing recommends this as a good season for pruning of ashes only, because the wound heals quicker while the sap is flowing.

Felt oak woods and coppices, and other barking trees, but complete the operation about the middle of the month. (6691.)

Routine culture. Attend to planted ground under, or to be put under, light culinary crops. (7037.)

Prepare ground for autumnal planting or forming of plantations by sowing, as the free-seeds ripen. (7817.)

Operate on ground for water, or other territorial improvements. Continue to build and execute plans determined on at an earlier season.

Remarks.

The weather is sometimes cold at the beginning, but is generally fine and steady and towards the middle of the month. By observing the column indicating the greatest variation of the thermometer in each month, it will be seen that it varies, in London, only two degrees in June, which is less than in any of the preceding months. In June, the variation is the same; but in March and October it is twice as much.
1. Kalendar of vegetable nature round London.

In the first week: the sedge-sparrow (Passer grun- dinarius), the fly-catcher (Muscicapa striaticeps), the wasp (Vespa vulgaris), and several species of bee and butterfly appear.

Second week: the burnet-moth (Sphinkis filipendula) and forest fly (Hippobosca equina) appear; bees swarm.

Third week: several kinds of butterflies, moths, beetles, and other insects appear.

Fourth week: insects abound; and singing-birds begin to retire to the woods, and leave off singing.

2. Kalendar of vegetable nature round London.

In the first week: water-lilies (Nymphaea et Nuphar) flower; also iris pseud-acorus, anthemis coronaria, polygonum persicaria, malva rotundifolia, and numerous other plants.

Second week: the vine, raspberry, and elder in full flower; also various Scotch roses (Rosa spinosissima), broom (Spartium), nettle (Urtica), and weeds in the ear.

Third week: the orchis, epilobium, iris xiphium and erianthus, the hardy iris and gladioli, and a great variety of garden and field plants in flower; also the wheat and many of the pasture grasses.

Fourth week: some black and red currants ripe, strawberries and raspberries in abundance, young strawberries and trees have nearly attained their length; oats and barley in flower; blue-bottle, seabiscus (Centauraea cyanus), and numerous others, in bloom.

Sow peas and beans once a-week or ten days. (360.)

Cucumbers for pickers. (4576.)

Gourds in the first week. (4211.)

Small salads and lettuce every week or ten days. (4078, and 3564.)

Radishes and spinach in the first week. (5771.)

Kidneybeans every fourth night, for succession. (5633.)

Endive about the 10th or 24th, for the 

main autumn and winter crops. (3581.)

Chervil twice in the month for summer use. (3581.)

Spinach, of quick-growing sorts, for summer and autumn consumption, according to the beginning and middle of the month. (3582.)

Turnips in the first week, for succession; and in the second and third week for a full autumn crop. (3588.)

Carrots (5717.) twice, for drawing young. Broccoli and borecole, in small portions, for succession; late in spring. (5552, and 5227.)

Onions to be drawn young.

To save seed. Mark out cauliflowers, lettuces, &c. and let them remain and send up their flower-stems. (6263.)

Protect when and where necessary. (2366.)

Propagate by bulbs, roots, offsets, slips in showery weather. (1887.)

Transplant. (3579.)

The brassica tribe, caroobas, endive, lettuce, and other plants and herbs, also plants reared in hot-beds.

Put garlic and comestible leaves in knots to check the progress of the flower of the strawberry. (3579.)

Stick and top peas; top beans; earth up finochio to blanc; also white beet. Thin, hoe, and stir the ground as before. Support with stakes, and water as far as practicable; in dry weather.

Turn up crops. (2292.)

Cut and dry herbs for winter use. Gather ripe seed. Discontinue cutting asparagus at the end of the month.

4. Hardy fruit department.

Prune and train the summer shoots of all descriptions of wall and trellis trees. (5110.)

Prune the shoots of fruit-shrubs, and of all fruit-trees, excepting hardy standards, which do not require this nicety. (2576.)

Routine culture. Mulch, water, fasten by stakes, water again, and rake out the weed; throw over cherry-trees and protect the fruit from the birds. Water strawberry plots every day in dry weather, desiring a little as the fruit begins to ripen.

Destroy insects. Strew sulphur over the mildew, water for the acarous; direct a stream of tobacco smoke against the aphids and other pests. Depend your fingers for the thorough eradication of grubs, which, at this season, are by far the most mischievous of garden enemies. (2880.)

Tree-fruit and cellar. As in last month. (2888.)

5. Culinary hot-house department.

Glass case without artificial heat. Raise hardy glass cases and runners on frames, and plants and runners, in the second or third week. Ridge out melons in good earth, in the last fortnight; cover with manure till the end of the third week. (3328, and 3329.)

Hot-beds. Keep up adequate temperatures for ripening the fruits by linings. Reinforce melon ridges with straw, and keep them in a dry and impregnate, as circumstances require. Attend to air, water, shade, and even nightly coverings after cold days. Keep up proper linings to your beds of pine-suckers.

Pinery. Attend to what was stated last month. If you want extraordinary large fruit, and do not mind losing others, apply the usual means of your viz. heat, water, and removal of all stem and root suckers. (5928.)

Forcing experiment. See last month. Keep up successive supplies of kidneybeans, strawberrv, and fruit-trees in pots. (3538.)

6. Flower-garden — Open ground department.

Sow a few hardy and half-hardy annuals for succession, as before. (6507, and 6513.)

Propagate, by cuttings, such plants as are proper for this bed, which as they go out of the pipe, and lay pinks and carnations towards the end of the month. (6406, and 6440.)

Take cuttings and other rootous plants, dry them in the shade and remove them to boxes or drawers in the store-room, wrap the finer sorts in papers. (6501.)

Transplant (3793.) annuals in the borders and in pots for autumn and winter flowering. Biennials and perennials may also be transplanted into nursery rows at this season, or even where they are finally to remain.

Routine culture. Mow, weed, hoe, rake, thin, stir, and dress; and keep up as complete an appearance of polish and high keeping as your strength of men and other means will permit. (6191, to 6501.)

Shade, shelter, water, and attend to cuttings coming into flower. Keep dry earwigs and all manner of insects. (2829.)

Go round the garden frequently and examine everything minutely, and reflect on what might be done to promote its growth and beauty. To aid you, imagine to be a garden which you were sent to criticise, and to be paid according to the number of faults you found. Or imagine it your neighbor's garden, or the garden of some one you hate. (7438, and 7439.)

7. Flower-garden — Hot-house department.

Glass case without artificial heat. Propagate the diaphanous plants by pipings under hand-glasses and frames. (6406.)

Hot-beds and pits. Put pots of carnations and pink pippins in gentle heat, which will facilitate the striking. (6406, and 6440.)

Do not forget to give head-room to your balsams and other tender annuals, which should now be noble-looking plants. Attend to pots of cuttings and seedlings; also to your stove plants put into this department for more rapid advancement.

Greenhouse. As soon as the mulberry comes into leaf remove the plants to a fit situation in the open air. Some plunge them in ashes; but the major part set them on scoria, gravel, or pavement, in a partially shaded situation, a cold bed at this season is a certain degree of shade are essential to their well-doing. (6533.)

Dry-stones. (6176.)

Give abundance of air night and day, but moderate as to water. Cease to water bulbs soon after they have done flowering; let them go slowly into a state of hybernation, and then take them out of their pots and dry out. (6533.)

Bark, or moist store. Increase your heat with the lengthening day, and prolonged sun, and by consequence increase the concouring agents of vegetation. Propagate by the usual means save seeds where you can; destroy insects, and attend to neatness. (6088. to 6705.)

8. Pleasure-ground and shrubbery.

Prune and regulate summer shoots, and take off suckers where not wanted to extend the bush or propagate the species. (6190.)
Routine culture. Weed, hoe, rake, stir the surface, support climbers, regulate the shoots of creepers, &c. Water and roll any new-laid gravel to combine it properly with the rest. Dress, roll, and edge lawns and turf in every form. Keep your eyes open to every part of the grounds at this season; for now perfect neatness and the utmost polish and high keeping is expected. Do not trust to what you are told to do in calendars, but think for yourself: calendars frequently make mere machines of gardeners; for though man is a thinking animal, yet he is also a lazy imitative animal, and will trust himself in any way and not even think, unless urged on by some strong motive. All your faults will be discovered, sooner or later, and rely on it you will receive a proportionate disgrace from your neighbors or visitors. If you are attentive to your duty your merits will be discovered in like manner, and you will receive appropriate credit and reputation, which is your capital stock in trade, on which you depend for your livelihood. (2372.)

Fruit-trees. Begin budding during the last fortnight. Look over all your newly grated and all other trees; rub off superfluous, irregular, or ill-placed shoots and suckers, and tie the weak grafts and dangling shoots from budded stocks to neat stakes. (2038.)

Ornamental trees and shrubs. Lay the summer shoots of roses, hard-edged evergreens, and other sorts which are proper to be propagated in this manner. In June, cuttings of young shoots properly ripened at the lower end. Bud rare sorts. (3065.)

Forest trees. Collect and sow elm-seed in the third or fourth week; or if you do not wish to sow it, lay it before the snow. (2053.) Seedlings of the more choice pines may be thinned where too thick, and the thinnings planted and shaded about the end of the month. (6927.) Gather Scotch elm-seed from the middle to the end of the month. (7332.) Attend to kitchen crops among transplanted trees, and in vacant places in general. (7067.)

Fell oak-coopices, if it has not been done before. The middle of this month will prove a better time, as to the trees, than the middle of May, as they will not have budged so much; but the bark will not peel so well. (6941. to 6957.)

Prune and thin the side shoots of the present season, from established trees. (6864.)

Routine culture. Seed newly planted tall hedge-row trees, where not done before. Attend to weeds everywhere, and to ground under-crop. Prepare ground for autumn sowing or planting.

Operations on grounds and buildings are carried on at this season with less advantage than in the three preceding months. The ground is hard and difficult to penetrate; and the moisture in new-built masonry dries too rapidly.

Remarks. This was called July month by the Saxons, and in it are more plants in flower than during any other. The hedge-gardener should now devote a considerable portion of his time to inspecting and drying specimens, duplicating, and triplicating, in order to acquire a stock to exchange with brother-gardeners or naturalists; or with booksellers, apothecaries, schoolmasters, and clergymen, for the loan of books, and for aid and instruction in study.

1. Calendar of animated nature round London.

In the first week: the cuckoo (Cuculus canorus) leaves off singing; the stone-curlew (Charadrius alexandrinus) calls from a stubble occasionally till the 10th; and the golden-crested wren (Motacilla regulus) now and then chirps.

Second week: the quail (Tetrao fontinaria) calls; the nighthawk (Capella sternaria), abounds.

Third week: young frogs migrate; hens moult.

Fourth week: the great horse-fly (Tabanus bovinus) appears; and partridges fly.

2. Calendar of vegetable nature round London.

In the first week: enhancer's nightshade (Circaea lutetiana) and lavender (Lavandula spica) in flower, and pinks and carnations in full bloom.

Second week: the fallen star (Tremetella nocturna) appears, also puff-balls (Lycoperdon bovista), and sometimes the common mushroom (Agaricus campestris).

Third week: raspberries and gooseberries ripen, potatoes in flower, asparagus in berry, the liliums in perfection.

Fourth week: the truffle (Tuber cibarium) now hunted or dug up in commons and forests; nightshade (Solanum nigricum), devil's bit (Scabiosa success), burnet-saxifrage (Pimpinella saxifraga), and a great number of plants in flower.

Sow (3071.) salads and lettuce in shady situations, for use immediately; turnips, radish, and salad crops. (3760.) Kidneybeans, in the first week, for a late full crop. (36337.) Peas and beans, in the first week, and a fortnight afterwards try a small sowing for a late crop; in the first week, to come in at the close of autumn; in the third week, for a winter crop. (3681.) Broccoli, before the 10th, for a late spring crop. (3557.) Finocchio, for succession, in the first fortnight. (4669.) Round-leaved spinnage, in the first week, in a shady border for a succession. (3771.) Triangular-leaved, or prickly spinnage, in the last week, in poor ground to stand the winter. (5775.) York and sugar-loaf cab-

ages, in the first week, for autumn use, and in the last week, for winter and spring. (3455.) Carrots, in a shady border. (3718.) Turnips twice or thrice, in showery weather. (3668.) Welsh onions; for which, sow onion seeds in the first week to last stand the winter. (3616.) Corn-andger and borage for young crops. (4222, and 4127.)

To save seed. Mark out the brassica tribe, and other esculents, in perfection, and let them shoot up flower-stems.

Propagate by slips, offsets, &c. where not done before, and where plants have completed their in-flowering, and are to be cut down as tarragon and other pet-herbs. (4003.)

Transplant (2073.) as before, and include celery and celeriac, endive, &c.

Routine culture. Stick and top peas and kidney-beans, top common beans, train cucumbers and gourds, earth up the leguminous crops and potatoes; hoe, thin, and stir the surface wherever necessary, among all descriptions of crops; water, as far as your time will permit, and particular crops require.

Taking crops (2969.) Take up shallots, and dry them for winter use; also rocambole and garlic when ready. Gather ripe seeds and onions, and cut herbs in blossom, drying and storing both. Gather the fruit of young gourds for pies, stews, and pickling.

Destroy insects, and ward off vermin. (3277.)

4. Hardy fruit department.

Plant strawberries in the open garden; and in pots for next winter's forcing. (4717.)

Prune, train, thin, and regulate all the summer shoots of the hedge and espalier trees, and dwarf and tall standards. (2573.)

Routine culture. Hoe and weed fruit-tree borders. Hang up nets, and mulch where necessary. Water alpine strawberries, which will now be in full bearing, every third or fourth day, unless in a shady situation.

Destroy (2575.) insects: keep earwigs, ants, boys, and idle women from fruits, as cherries, &c. approaching to a state of ripeness.

Fruit-room. (2028.) This will now be empty; clean and wash every part of it, and air it well for occasional summer and next winter's use.
Fruit-cellar. (2262.) If you have attended properly to casking up keeping-apples and pears, you will still have a supply, and even of grapes in some cases. If the cellar gets too warm, the casks should be removed to the ice-house.

5. Culinary hot-house department.

Glass case without artificial heat. Plant out meadowsweet, umbel, and rue, and if you are favoring to increase more delicate aquatics, see to the keeping up a regular heat.

Hot-beds and pits. (2678.) Little use is now made of them by the florist, unless for propagation of stove plants. Attend to cuttings from whatever department you are favoring to increase to see more delicate aquatics, see to the keeping up a regular heat.

Green-house. (2611.) This will now be filled with pots of annuals, which only require thinning now and then till a certain growth; and then only common routine culture.

Dry-blood. (2606.) Some set out a part of the succulent tribe at this season. If you do, let it in a very warm situation: heavy and continued rains prove very injurious to succulents in the open air.

Flower-houses. (3536.) Expose those houses, where crops are taken, to the natural climate, by removing as far as possible, the roof, and even the ends and front, if they aremoveable. (3110)

6. Flower-garden. — Open ground department.

Sow a few annuals, for succession, and prolongation in pots through the winter.

- Propagate (6490.) from cuttings of plants going out of flower; from rooted slips of such as are ripening their seeds, as auriculas and the primula tribe. Go on piping and laying the dianthus tribe. (6413.)

Take up bulbs as they go out of flower: this work should generally be completed by the end of the first week, unless for the lily tribe, the colchicum, and a few others.

Transplant late sowings of annuals, and also biennials, of auriculas and nursery stock in flower.

Routine culture. Eradicate all weeds the moment they appear: keep the surface always fresh, and rather rough, never smooth and battered. It is better to have little clods and knots of earth, than to have a naked or dug surface as smooth as a table. The clods and knots make variety of light and shade, and are besides more favorable for the admission of air, heat, and water to the roots. Shade, shelter, and water. Gather seeds as they ripen, and dry them in the seed-room or lofts, the windows being open. Destroy insect, cut broken stalks, and diseased parts of plants. Cut down stalks which have done flowering, and remove all decayed leaves.

Gather flowers neatly with a knife, and so as not to disfigure the plant. (6195.) Gather in general from the reserve-garden, so as not to disfigure the border.

Store-room. (1704.) Look over your bulbs now and then, to see that none get mouldy. See also to your newly put-up seeds. (1765.)

7. Flower-garden. — Hot-house department.

Glass case without artificial heat. (5880.) Most of these, at this season, are given up to the kitchen-garden, or used to protect at nights the tender annuals, some of which, as the humble and sensitive plant, cannot so well be put out in the borders. (6724 and 6725.)

Hot-beds and pits. (2678.) Little use is now made of them by the florist, unless for propagation of stove plants. Attend to cuttings from whatever department you are favoring to increase to see more delicate aquatics, see to the keeping up a regular heat.

Green-house. (2611.) This will now be filled with pots of annuals, which only require thinning now and then till a certain growth; and then only common routine culture.

Dry-blood. (2606.) Some set out a part of the succulent tribe at this season. If you do, let it in a very warm situation: heavy and continued rains prove very injurious to succulents in the open air.

Flower-houses. (3536.) Expose those houses, where crops are taken, to the natural climate, by removing as far as possible, the roof, and even the ends and front, if they are moveable. (3110)

8. Pleasure-ground and shrubbery.

Prune (2116) as in last month: box-edgings and evergreen hedges in the last week of this month, if the season is a fair one. (6190.)

Routine culture as in June. (6207.)

Launs. (6191. and 6207.) Attend to these, according as the weather may be showery or otherwise. In dry weather, set your men to mowing at three o'clock, and let them rest early to till three o'clock: in moist weather the time of the day is of less consequence. In France and Italy, the working goes on even during summer; this may be said of the principal part of their work early in the morning, and late in the evening.

Gravel-walks. Weed and roll these in moist weather; the gravel settles, and the gravel become loose, water and roll. (1957.)

Fruit-trees. Attend to budding, and look over your grafted trees; pinch off all ourbating shoots and suckers. (3009.)

Ornamental trees and shrubs. Continue laying summer shoots, and plant cuttings and buds as in last month. (6205.)

Fruit trees. Sow elm-seed; attend to weeding and clearing all beds and rows of seedlings, or other nurseries, and of transplanted trees. (7023.)

Prune (2116) evergreens in the last week, if the summer has been so favorable as nearly to ripen the wood.

Routine culture. Attend to kitchen, or field crops, among young plantations; and to large weeds everywhere. Do not forget hedges and other fences: keep all sorts of fences at all times in repair. (6238.) Few operations in landscape-gardening can now be commenced; but, some, as excavating for water, &c. may go on.

AUGUST.

Weather at London. Average of the Temp- Thermometer. Greatest Variation from the Average of the Barometer. Quantity of Rain. 0.824 inch. London - 65 85 2 7 29 0 50 0 Edinburgh 60 6 29 828 29 172 585 Dublin 62 81 10. This is the baron, or wettest month of the Saxons; many seeds of herbaceous vegetables ripen in this month, and many sorts of culinary crops, raised in the open garden, are now in perfection. Insects, especially the winged tribes, now abound; and the young gardener should be assiduous in collecting them for the same object as he collects specimens of plants. By carrying a small bag in his pocket, he may pick them up while at work.

Third week: the black-eyed marble-butterfly (Papilio semecle) appears; various birds resume their spring notes.

Fourth week: the nuthatch (Sitta europaea) chatters; the stone-curlew (Charadrius alexandrinus) whistles at night; the goatsucker (Caprimulgus europaeus) the young ones; (Strix alba) make a noise in the evening; robin-redbreast (Miliarca rubecula) sings; and rocks root on their nest-trees.
2. Kalendarial of vegetable nature round London.

In the first week; milliot (Trifolium officinale), rue (Ruta graveolens), yellow scuracy (Pieris floricola), and burdock (Arctium lappa), in flower; the bread-corn ripe.

Second week; wild clary (Salvia verbenacea), mow-dow-rue (Thalictrum flavum), ploughman’s spike-rush (Coryza squarrosa), and various other natives, in flower.

Third week; the mallow (Malva), lavatera, holly-hock (Alcea rosea), and lobelia, among the garden-flowers, and the polyonions and potanomeons among the wild plants, now in blossom.

Fourth week; the autumnal crocus (Cochleum autumnale), astor, solidago, senecio paludosus, teasel (Dipsacus fullonum), and various other plants, in flower; the earlier varieties of all the hardy kernel-fruits ripe.

Sow (2071) turnip for a main crop, in the first week; but sowings made after the 15th seldom fully succeed (3008); make frequent sowings of small salading, radishes, and lettuce (3700); the latter may now be sown for winter and spring use, this being the most natural season for sowing biennials. (4282)

Some of the large sorts of cabbage, in the first week, and in the autumn of the following year and subsequent winter; and early sorts in the first week, for coleworts next winter and spring. Spinage, in the first or second weeks, for a main winter crop. (3723) Carrots in the first and third weeks for drawing young in spring. (3718) Endive and corn-salad for winter and spring; chervil for a late crop; and tresses for a full winter crop of the felicitous, scurry-grass, and blessed-thistle for next year. Cauliflowers twice, in the third and fourth week, for crops, to stand over the winter, in sheltered borders, or under frames. American cress, in the last fortnight, for a spring crop.

Propagate (1987) by slips and cuttings, where necessary. Transplant (2079), as in last month, and include leeks, perennial herbs, &c.

Routine culture. Displace the suckers from such artichoke heads as you would grow to the greatest magnitude; stick peas and runner kidneybeans; earth up the brassica and leguminous tribe, and potatoes in so far as requisite. Land out celery, endive, white beet, turnip, endivechio, &c; for the small-leafed, thin, weed, stir the surface, water, shade, and attend to neatness and order; and clear off all crops the moment they are done with. (2097)

Tender crops. (2090) Take up the alliances tribes as before; gather pickling cucumbers; cut herbs; gather ripe seeds.

Destroy insects. (2276.)

4. Hardy fruit department.

Plant (2077) strawberries, as directed for last month.

Prune (2273), regulate, train, and otherwise arrange the summer shoots of all fruit-trees as directed for last month.

Routine culture. Hoe, rake, weed, and stir the surface; dress berry compassionately, and in general under and around all fruit-trees. Where fruit is beginning to ripen, be very moderate in thinning the leaves. Mat up small fruits on north walls, in tended for the berry company, till late in autumn; water spring-planted trees in dry weather, also strawberry-plants in blossom and fruit. Dress strawberry-beds that have done bearing (4725, and 4727).

Take (2290) goosberries and currants, with the fruit-scarcers or tongs. Apricots and such wall-fruits as is ripe with the fruit-gatherer. (See figs. 141. to 145.)

Destroy (2276) insects; the acurus will now be your greatest enemy.

5. Culinary hot-house department.

Glass case without artificial heat. See last month.

Hot-beds. (5278.) Attend to such cuttings as are forwarding in these, and to late crops of tender annuals. Prepare successions of tender annuals for the greenhouse.

Green-house. (6211.) Attend to your tender annuals; and do not forget creepers, and vines, and such plants as being planted in the ground cannot be turned out. (6647, to 6651.)

Dry-stone. (6176.) About the end of the month, it will be safe to replace such plants as you had ventured in the open air. Any you put in cold-pits, may remain a month longer. (6663, to 6668.)

Bark, or moist stoe. (6214.) See last month. Attend to creepers, climbers, and vines, also aquatics, which, if in a proper situation, will now be in great perfection, and highly beautiful. (6180.)

8. Pleasure-ground and shrubbery.

Plant (2077) evergreens towards the end of the month; water, mulch, and shade, for some days, if very delicate sorts. (3083.)

Prune evergreens (2110;) roses for forcing. (6538 and 6622.)

Routine culture. Hoe, rake, weed, &c. as before. Prepare ground for planting; dress gravel and grass as in June and July.

Form and repair lawns, by turfing or sowing. It is now an excellent season for sowing lawns. See that you make use of the proper grasses, according to the soil and situation. Attend to gravel walks. (1957.)

Fruit-trees. (2039.) Finish budding of the late va...
KALENARIAL INDEX.

rieties of the stowe fruits, before the middle of the month. (3056.) Look over the grafted trees, and slacken the bandages of your earlier and most ad

Ornamental trees and shrubs. Plant cuttings of hardy evergreens, as laurel-bay, privet, box, &c. in the late fortnight. (7025.) Provide box, and hawthorn

to encourage American and other sorts. (1810.) Go on with budding rare species.

Forest trees. Sow elm-seed, if you have not done it already; or do not choose to defer it till spring. (7025.) Routine culture. Hoe, weed, &c. and keep every part in perfect order; look to your kitchen-

In the first week: young broods of goldfiches (Fringilla carduelis) appear; the linnet (Fringilla lilina) congregates; the bull (Bos taurus) makes his shrill autumnal noise; and swallows (Hirundo rustica) sing.

Second week: common owls (Strix flammeus) hoot; the saffron-butterfly (Papilio lyale) and willow red under-wing moth (Phalaena pecta) appear; hornbeam (Ulmus laevis) are now cheap. Be ready.

Third week: the ring-ouzel (Turdus torquatus) appears; the flycatcher (Muscicapa arctica) with the nestlings.

Fourth week: the star (Sturnus vulgaris) congregates; the wood-lark (Alauda arbovens) sings; the woodcock (Scolopax rusticola) and fieldfare (Turdus pilaris) appear; and the swallow (Hirundo rustica) departs.

2. Kalender of vegetable nature round London.

In the first week: the fungus balusters albus appears; traveller’s joy (Clematis alba) and panama pantheris in flower.

Second week: the catkins of the hazel and birch form flowers; apple blossoms, and green, red, and black berries found on the bramble at the same time; leaves of the sycamore, birch, lime, mountain-ash, and elm begin to change.

Third week: the ivy (Hedera helix), laurel (Prunus laurocerasus), and hawthorn (Ulex europaeus) in flower.

Fourth week: hips, haws, and nuts ripe; leaves of plane-tree (Platanus) tawny; of the hazel, yellow; of the oak, yellowish green; of the sycamore, dirty brown; of the maple, pale yellow; of the ash, fine lemon; of the elm, orange; of the hawthorn, tawny yellow; of the cherry, red; of the hornbeam, bright yellow; of the willow, hoary.

Sow (2071.) small salads twice or thrice on a south border, chervil, corn-salad, cross of sorts may still be sown to stand over winter. (4622 to 4705.) Radishes in the first week for a late autumn crop. (5700.) Lettuces in the first week for standing the winter under a south wall, and under cold-frames. (5250.) Spinach in the first fortnight for use late in spring. (5715.)

Protect cucumbers and melons, at night, by matting curtains of sacret cloth, or by close green. (5270.) 

Propagate (1855.) as in April, culinary herbs and under-shrubs.

Transplant (3979.) all articles intended for use the current autumn, during the first week. The brassica tribe, leeks, celery, endive, &c. for winter and spring use. Sowling cauliflowers, where you think you can ensure their standing through the winter. Try a bed of sandy loam or lime rubbish under a tree or south wall. (5246.) Make plantations of herbs.

Routine culture. Earthen up and stir only in dry weather. Stick, stop, support, cut down, blanch, and thin where you see it necessary; no time to be lost at this season.

Take up potatoes. (2290.) Take up potatoes, and do it effectually. Gather picking cucumbers, onions, nasturtium-seeds, and other picking articles. Gather herbs and take ripe seed. Remove all decayed leaves, stalks, stems, and the refuse of all crops, which have been taken, so as to preserve order and neatness, and make way for other crops or winter fallow. (3000.)

Destruct pests and vermin. (2796.)

Storeroom and cellar. Dress, sort, and put up seeds which have been well dried. Finish housing edible bulbs of the alliaceous tribe and potatoes. (2298 and 2299.)

4. Hardy fruit department.

Plant (3077.) for a main plantation, this being the best month in the year for that purpose. (4717.) Pot strawberries for forcing. (3036.)

Prepare ground for planting, and towards the end of the month; if the word of peaches and apricot trees be ripe you may remove them.

Prune (2110.) and regulate summer shoots, but cut little after the middle of the month. Thin leaves sprouting.

Routine culture. Provide composts for recruiting old borders and forming new ones. Provide choice fruit, especially grapes, from birds and flies. After the crops of wall-trees or compartment borders are gathered, dig and dress the borders. Dress and fork up strawberry-beds.

Take up pears and apples for keeping a few months; in general, the long keeping sorts ripen late in the season.

5. Culinary hot-house department.

Glass case without artificial heat. Sow small sal-

Hot-beds and pits. Attend to late crops of melons and cucumbers; keep up the temperature, and be on the alert at night to secure a proper amount of light, and do not neglect to build mushroom-beds, either in or out of doors. This month and March are the two best seasons. Plant suckers and crowns of pines on rotten tan placed on dung, or other fermenting beds or pits.

Pinery. (3087.) You will still have abundance of fruit; attend to what was said in July. Renovate your bark or leaf beds when necessary, and keep up the full heat till your fruit is chiefly ripened off, or
removal (pot and all) to the fruit-room to ripen leisurely. Your young plants will grow faster in this month than in any month of the year.

For green-houses. (2034.) Late crops of grapes will be coming in, but most of the forcing-houses will now be in a state of rest. Keep off all the sashes, unless you mean to force very early, in which case cover the house with mats from the sun, and admit air from the north, in order to promote a cool, dry atmosphere as best for hyperbarnia.

6. Flower-garden. — Open ground department.

Sow the primula tribe, if not done last month. (6335. and 6885.) The seeds of most biennials and perennials may be sown this month with great advantage, provided you can afford protection to them in winter. On the whole, however, it appears better to defer the business till spring, unless with a few sorts which sometimes lie a whole year before they come up, when sown at that season. Among them may be enumerated columbine, agrimony, chelone, &c. If sown this month they will come up the following spring, and they will flower the same season. (64555.)

Propagate (1955.) by all the modes, but more especially from slips, rooted or unrooted, the stalky part of herbaceous plants being now of a proper texture and maturity for this purpose.

Plant crocus and other bulbs, and such autumn-flowering bulbs as you have neglected to plant early in the season. (6253.)

Transplant as in last month. (2078.)

Shelter. (2063.) If the end of the month be wet, hop and mat such plants as will be injured by over-much water. Among these are the primula tribe and tender annuals planted in groups over the borders; also bulbs, as the tuberose and Guernsey lily, planted orplanted in the borders.

Routine culture. Prepare ground for florists' flowers. Trench and sift the earth where tulips and hyacinths are to be planted, at least three feet deep.

Store-room. See to roots and seeds. (1704.)

7. Flower-garden. — Hot-house department.

Glass case without artificial heat. (2986.) Replace the more tender auriculas in the frames, but keep off the glasses, excepting when it rains.

Hot-beds. See last month. (2578.) Most of the green-house and hot-house plants will now be advanced: remove them to cold-frames, or to the green-house or dry-store, according to their natures, to harden them gradually. Some may go directly to the dry-store.

Green-house. The beginning of this month is a fit time to repair, paint, glaze, and clean the bluestones, &c., and to give a general inspection of house in crop. Replace some of the more tender plants from the open air at the beginning, and the whole in the course of the last month of the dress. Plant them properly, and set them in natural groups, not in the usual method. (See particularly 6685.)

Remarks. Grapes and other late fruits ripen during this month, and some main culinary crops are gathered and housed. A few specimens of plants may still be collected during the month, but the season for the gathering of species of the animal kingdom. Not one animated being should be neglected from the warm uplands. Collections of spiders are best made during this month, and the young gardener may continue to dissect and study the habits of these creatures.

In the first week: the red-wing (Turdus iliacus) arrives; snakes and vipers bury themselves.

Second week: hooded crows (Corvus cornix) and wood-pigeons (Columba palumbus) arrive; hens, curlews, and chaffinches (Fringilla coelebs) congregate, and prepare for migration, leaving their mates in this month.

Third week: the snipe (Scolopax gallica) appears in the meadows; wildgeese (Anas platyrhynchos) leave the fens, and go to the rye-lands.

Fourth week: the tortoise (Testudo graeca) begins to bury himself in the ground, that he may visit his next-nest; some larks (Alauda) sing, and the woodcock (Scolopax rusticola) returns; spiders' webs abound.

2. Kalender of vegetable nature round London.

In the first week: strawberry-tree (Arbutus unedo), holly (Ilex aquifolium), China hollycock (Hippophae rhamnoides), and China aster (Aster chinensis), in bloom.

Second week: cattins of some species of salt formed; leaves of the asp almost all off; of the Spanish chestnut, yellow of the sunflower (Helianthus annuus), scarlet; of the common birch, yellow and gold; and of the weeping-birch, gold and bright-red colored.

Third week: chelmary calyca in flower; some horse-chestnuts and acacias quite denuded of leaves.
Fourth week: various plants, especially annuals, continue in flower; leaves of marsh-elder (San- 
buscus ebulus), of a fine pink; of stag's-horn sumach, of a bright red; of the American gipsies, of 
fine shades of yellow, orange, red, and purple.

Sow (2071.) small salads, lettuces, and radishes in the first week. If mild weather continues 
they will come in about Christmas. Mazagan beans, and hotspur or frame-peas (2001.), in 
the third week, to see if they will stand the 
winter. (2016.)

To save seed. Transplant cabbage, savoy, beet, parsley, carrot, turnip, batchet and Welsh 
onion. When what is said (1896. and 3337.) as to the danger of bastardy among the cruciferae 
family. (3826.)

Protect all newly risen annuals, and newly depo-
sited seeds, as also parsley on the approach of 
frost. (2006.)

Propagate (1885.) the allaceous tribe and culinary 
perennials. Transplant (2079.) endive and lettuce on warm 
orders, and cabbages in close rows or in beds, to 
remain in that state till wanted as plants in spring. 
Cauliflowers in the last week, to receive the pro-
tection of frames. (3545.)

Routine culture. Earth up and stir the surface 
over in the dry weather. Hoe, rake, thin, weed, 
and dress off all beds of winter crops. Protect caul-
iflowers from heavy rains by breaking a large 
leaf and laying it over the flowers. As crows are cleared, dig and trench the vacant ground.

Take up (2290.) potatoes, Jerusalem artichokes, 
beet, parsnip, saffety, scorzonera, skirret, tap-rooted 
tarragon, and horse-radish two summers' growth. 
Preserve them in dry sand. Destroy insects. (2886.)

Root-cellar. See that this is perfectly dry, and that 
abundance of sand is laid over the roots. Store-room. Finish cleaning and putting up seeds, 
and see that all you have are in a good state, and 
not injured by vermin. (6414.)

4. Hardy fruit department.

Plant (2077.) all sorts of hardy fruit-trees as soon 
as the leaves have dropped off, but not before, as 
some practise; for in this state neither their shoots 
or roots are ripe. Give ample waterings at 
planting. Protect (2096.) fig-trees as soon as their leaves 
have fallen. Shield late grapes from frost by mat-
ing. Immure pots containing plants intended to be 
transplanted into dry old tan or ashes to save their 
roots from frost. Prune (2110.) all sorts of fruit-trees excepting the 
plum, cherry, peach, pear, and fig, which being trees of 
small growth, or mellett, or medulla, are apt to die back from the point of 
section-cut place, when pruned at this season, and 
are therefore better left till spring.

Framework. Prepare ground for new plant-
ations. Dig and rodge up where the trees are 
already pruned. Winter-dress strawberry-beds. 
Take (2290.) grapes, apples, pears, and other 
fruits.

Frutoom. (2289.) Lay all fruits first here till 
thoroughly dried, and then barrel up the longest 
season, and remove them to the fruit-cellar.

5. Culinary hot-house department.

Glass case without artificial heat. (2086.) Plant 
lettuce and cauliflowers under frames, to stand the 
winter. Sow small salads in the second week, and 
last fortnight under frames or hand-glasses. 
Hot-beds and pits. (2078.) Keep up the declining 
death of such beds as have not yet ripened off their 
crops. Dress those which have done bearing, and 
prick in lettuce or cauliflower plants. Prepare more 
small frames for forcing other herbs in pots or boxes. Get up mushroom-beds if not 
done in September. Plants pine-suckers in the open 
bed or pot, as they are taken off. Cover well at 
nights. (2006.)

Pinery. This is a general time for shifting and 
renewing the bark-bed. Do not put the plants into 
very deep boxes, as they were not grown much in 
the pot. Till the last week of the month your plants 
will grow rapidly. (2007.)

Forcing-houses. (2642.) Prune and in general 
clean and repair the houses and flues, mend 
broken glass, and paint the whole when necessary. (2095.)

6. Flower-garden. — Open ground 
department.

Sow (2071.) annuals in pots, for prolongation, in 
cold frames and pits, and some of the hardier sorts 
in warm borders, to come in early next spring, if 
the winter should prove mild. The sorts fit for 
this are larkspur, adonis, belvedere, pansy, persi-
aria, annual stock, and strawberry blite.

Propagate (1885.), but chiefly at this season by 
dividing the root, as of daisies and of other edging 
plants, iris, &c. Plant most of the border-bulbs about the end of this 
month, and you may even plant florists' ame-
mones in properly prepared beds. (2077.)

Transplant (2075.) biennials and perennials, in 
the flower-mat, to stand the spring weather. Other 
plants may be moved where they are finally to remain. (6490. and 6505.)

Protect (2005.) auriculas, carnations, and other 
flowers' plants from heavy rains by mats and 
yearly glasses. Begin at the end of the month 
to remove dahlia roots to be dried in an open shed, 
and then carried to the store-room.

Routine culture as in last month. Prepare com-
pots. Stir the ground only in dry weather. If 
the season has been very dry, flower-borders may 
be dug over for the sake of the end of the month. Attend 
above all things, to neatness. Do not trust to 
your calendar for directions in this, or any point, 
but endow your brain with the knowledge, and 
try and look at your works with the eye of 
a critic and an enemy, or even of a stranger. (7438.)

7. Flower-garden. — Hot-house depart-
ment.

Glass case without artificial heat. (2086.) Begin 
about the middle of the month to fill frames and 
surround with mignonette, stocks, &c. for pro-
longation through the winter.

Hot-beds and pits. (2078.) Roses which have been 
a time state in a state of hyperborean and in the 
shade, may now be moved from their bottom bed, as may 
hyacinths and other bulbs. Water-glasses may now be brought into use. 
Observe in the first piece, the place 
and time, if possible, to plant from bulbs in earth for a week or two 
before the breaking, which will make them strike roots more 
freely, and then take them up and put them in the 
water-glasses. Force them forward a week or two in 
frames, before you remove them to the drawing-
room. Continue to plant some every fortnight for 
succession. (6302.)

Grecian flowers. (211.) Replace all your plants, if 
you have not already done so. All your winter's 
credit depends on the style in which you 
give air and night, unless the thermometer drop 
to 35 degrees. (6211.)

Dry-stone. (6176.) Apply fires towards the end 
of the night, so as to keep a medium temperature 
with fire; 46 degrees 0. degrees will serve the 
plants for the winter. Pot and set in bulbs of most 
sorts. Bark, or moist stone. Lessen your temperature by degrees; and also your air and water. A good 
medium heat for this month will be 70 degrees, which will require fire-heat, even if the bark-bed is 
in full force. (6214. to 6216.)

8. Pleasure-ground and shrubbery.

Plant (2071.) all the hardier trees and shrubs 
where the ground is not apt to be rendered very 
moist; but during a very dry season, do not have 
till spring. This is the best season for planting.

Prune (2110.) evergreens; but finish, if possible, in 
the beginning of the month. Deciduous sorts as 
soon as the leaves fall.

Routine culture. Clear away all refuse, weeds, 
and decayed twiggs. Roll, mow, sweep, hoe, weed, and remove all 
weeds and dirt. (2078.)

Form and repair tawnys as before. (2100. and 2101.)

Fruit-trees. Sow for stocks as directed for last 
month. The plum, cherry, almond, medlar, apple, 
pear, quince, barberry, service-fruit, walnut, filbert, 
and common hazel-nut, may now be sown to greater 
advantage than in spring, provided you can keep 
the vermin from them during winter. Lay the

KALENDARIAL INDEX.
mulberry, or any other sort generally propagated in that way. Plant cuttings of elder; but it is rather too late for the ribes tribe. Remove raspberry suckers. Remove fruit-trees to their final situations, as soon as they have lost their leaves. This month, in all dry situations, is the best month in the year for transplanting fruit-trees.

Ornamental trees and shrubs. Sow the seeds of deciduous sorts as their wood ripens. Plant out in nursery rows; shelter where requisite. (2206.)

Forest trees. Sow most sorts, as directed for last month; but take care to guard against vermin. Gather haws, sea and holly berries, hips, &c. and take them to the rot-heap. Lay and propagate by cuttings of some of the plum-grown willows and poplars. Plant and prune in the nursery lines as required. (6823. to 7037.)

1. Kalendarial index.

REMARKS.

This is the windswept month of the Saxons; it is generally also cold and moist, and one of the most disagreeable for the laboring gardener, but he may converse himself with the shrubbery of the oak, larch, &c. so large as to be worth barking.

Prepare for planting, as directed for last month. This is a very fit season for draining, which may be continued; for it clears the weather, when men can work out of doors, till the planting season returns. In this way the men may be kept on without loss either to themselves or you. (6817.)

Operations on ground should now be carried on vigorously; but buildings should be completed, if possible, by the middle of the month.

4. Hardy fruit department.

Plant (2977.) all sorts of fruit-trees, as directed for last month. Choose dry weather. Water to settle the earth. Stake where required, and mulch (2908.) both root and stem, where you wish the trees to do well. Mulching the stem is particularly useless, and very little serviceable, and especially for the pithy-wooded sorts.

Prune (2110.) the vine, and other very hardy fruit-trees; the apricot, peach, and nectarine had better be deferred till spring.

Routine culture. Dig and dress wherever pruning admits; or where you have not been able to overtake the work last month.

Take (2906.) such apples and pears as still remain on the trees during the first week; dry them well in the fruit-room, and then barrel or jar up the long-keepe for the cellar.

Fruit-room. (2928.) Examine such bunches of grapes, and branches of plums and currants, as you have hung up to preserve the fruit; and pick off all decaying berries. Look over all the other fruits, and attend to medlars, quinces, and services.

5. Culinary hot-house department.

Glass case without artificial heat. (2986.) Sow small salads and peas and beans, either to transplant or to remain after moving the frames. Transplant lettuces and cauliflowers from frames to be covered with hand-cures. Attend to air and removing decayed leaves.

Hot-beds and pits. (2978.) Sow small salads, force mint, and other herbs. Try sowing of radishes on a moderate hot-bed. Transplant lettuces from the cold-frames to force them forward. Begin to force asparagus six weeks before the expected demand. Build mushrooms-beds; if under cover, it will be better.

Pinery. (2997.) Moderate every stimulus to vegetation; because, for the proper well-being of plants, it is requisite they should all go on in harmony. Heat, air, and water, art can supply; but light, in any thing like adequate quantities for vegetation, is beyond the power of man: therefore let your heat, air, and water, be in a proportion to the quantity required by the plants. (6995.)

Forsage-houses. Some begin this month; if so, begin the usual course. Dig and dress the borders; prune, train, paint, and fasten the house, &c. so that the end of the month, which is much the best time. (3338.)

6. Flower-garden. — Open ground department.

Plant (2977.) dried roots of border-flowers. (6592.) Transplant (2979.) biennials at the beginning of the month, if the weather is very fine: but this work is better deferred till spring. (2504. and 6865.)

Protect (3506.) tender roots by litter, leaves, tan, ashes, or landing up trees by mats, or straw covered with mats or nets. Take care of seedlings.
Routine culture. Collect earths, composts, and manures; and, in general, finish digging among herbaceous flowers by the middle of the month. Asters and such-like plants are often only checked in their growth and flowering by the frosts and rains; attend to them, as they are apt to be blown about, and be disfigured at this season. In cutting them over after the ground is dug, choose a dry day, and obliterate the prints of your feet with a fork. Mow as occasion requires.

Storeroom. (704.) Look at such bulbs as you are keeping for spring planting.

Bees. (748.) See that these are properly protected by straw covers, or by being placed in the bee-house.

Flower-garden. Hot-house department.

Glass case without artificial heat. (2866.) Take care of alpines and the primula tribe. Also of the annauls and perennials intended for forcing. Guard against damp by admitting air; and to do this effectually, always remove the sashes in the daytime; or, if the frames are being in front of stores, do not admit of this, till or elevate them in front, as high at least as the plane of the sun's rays at noon.

Hot-beds and pits. (3578.) Go on forcing all manner of flower bulbs, shrubs, and the perennial plants, and take in now and then a few pots of mignonette, to keep up a constant supply in full flower for the drawing-room. Blow Dutch roots in water-glasses as before.

Green house. (6211.) Medium temperature, with fire-heat, 42 degrees, maximum 44 degrees. Water sparingly; give air as the weather will permit; and see to neatness. Encourage mouldiness on the surface of the pots, also weeds and decayed leaves; these being great ornaments at this season, and highly useful for the plants.

Dry-stove. (6176.) Minimum temperature, with fire-heat, 45 degrees, maximum 50 degrees. Successions require very little water at any time, but especially at this season.

Bark, or moist stove. (6214.) Your medium temperature may now be 65 degrees, or less; but never exceeding a maximum of 75 degrees, and a maximum of 75 degrees. Lessen water and air, as light and heat are lessened. See that bulbs receive proper treatment, as these will produce your finest spring-flowers, especially the crinums and amaryllids.

8. Pleasure-ground and shrubbery.

Plant. (2077.) Deciduous trees, and shrubs of the hardier kinds, as long as the weather continues dry.

Prune and cut hedges. (2110.)

Protect delicate American trees, as magnolias, and shrubs not yet fully acclimated, as the Chinese rose, Reel, mock orange, and sweet tift. Attend to fallen leaves. (1631. and 6201.)

Turf may still be laid, but it is now too late to form or repair lawns by sowing grass-seeds. (2101.) Prepare for planting, by levelling, digging, trenching, &c. (1563. to 1571.)

Fruit-trees. (4691.) Plant only in mild and rather dry weather; mulch, water to settle the earth around the roots, and stake as circumstances require. Forward delayed work as to fruit-trees, for after the middle of the month it is better not to touch them till February.

Ornamental trees and shrubs. Complete what should have been done last month, as to planting, laying, taking off layers, &c. (7031.) Prune the more hardy sorts in the lines, and protect such as are tender by the usual means.

Forest trees. Finish sowing the larger seeds before severe weather sets in. Complete all other nursery operations for the season, if possible. Pruning the plants in the open air may be the last operation. Gather cones, acorn, masts, nuts, keys, and berries for immediate sowings, or the loft or rot-heap, according to their nature, and your skill and circumstances. (9863. to 7057.)

Plant in all temperate weather, and moderately dry situations. (2076.)

Thin, fell, and prune deciduous trees, as in last month. Cut, plash, and repair hedges; and more especially the hawthorn kind. (6017.)

Dead fences of every description, excepting mortar-walls, may now be attended to; but avoid building in December and January, even the smallest wall is better not at this season, and its effects equally so.

Operate on ground, water, rocks, woods, and timber excrescences; but by no means on buildings where mortar is used.

DECEMBER.

REMARKS.

Winter month. Sax. Cold, but dry. The gardener's operations are chiefly of the laborious kind; but the days are short and the nights long. In the first week the young gardener will examine himself as to his professional and intellectual progress during the bye-past year. If he can contents himself with merely excelling his fellows, he is lost; let him aspire at professional perfection, and high reputation among good and scientific men.

The mole (Talpa europaea) throws up hillocks; the December moth (Eriogaster populii, Salm.) appears about the beginning of the month, the latter and the yellowish quaker (Noctua flaveola, Salm.) about the end of the month.

2. Kalendar of vegetable nature round London.

Some of the last month's plants continue in flower, according to the weather.

Sow (3071.) peas and beans, and a few radishes (3560. and 3601.), as for last month. Choose the very mildest weather, and consider the final result as extremely uncertain.

Protect (2936.) beans sown thick for transplanting, and parsley intended for daily use, with tiers; celery and lettuce, and any plants with litter which you have not been able to land up, as artichokes, asparagus, &c.

To save seed. Transplant cabbages, if you have neglected it until so unit a season.

Routine culture. Attend to this only in the best weather, and chiefly in the middle of the day. Earth up peas and beans, or cover their stems with ashes, sawdust, or old man. Earth up celery when dry.

Tip any endive, cardoons, and white beet which has been neglected. Weed, but do not depend on the hoe, and only attempt to stir dry grounds; as stirring clayey lands at this season will do much more harm than good.

Take up edible roots and full-grown vegetables with exculent leaves, as the borchieles, and plant the latter in some open shed for daily use.

Destroy (2576.) slugs, snails, mice, and other vermin.

Rod-cellars, seed, and storeroom. (1702. to 1705.) See that these and what they contain, be kept in perfect order.

Ice-house. (1730.) Fill this, if it not done last month.

4. Hardy fruit-department.

Plant. (2077.) the harder trees, as the apple, pear, gooseberry, currant, &c. in mild weather. (4691.)

Prune as directed for last month; but omit all the operation in severe weather. (2110.) Partially unnil or unile trained trees, and wash their boughs and shoots, as well as the walls and trellises, with any glutinous and saline fluid.

Routine culture. Trench, dig, and ridge up the
5. Culinary hot-house department.

Glass case without artificial heat. (2686.) Sow small salads, radishes, and lettuce; if the weather proves mild they may do some good. Weeds, take off decayed leaves, and give abundance of air in dry weather. Protect, in severe frosts, by mats or litter.

Hot-beds and pits. (1704, 1705.) Begin to force asparagus, sow small salads, and transplant lettuce to be forced forward. Use the transplanter, in order that no check may be given, or any occasion for watering produced. Prepare cucumber-beds; or if you have begun see to them. Light is the grand thing to be attended to, for heat, air, water, and earth you can command at pleasure. Force mint, attend to mush-rooms, and compost-making; procuring earth, manures &c. Cover up at nights with all care; but avoid dips, by always giving a little air on fine days, and all night, when there is danger of steam of dung.

Pinery. (1707.) Keep a steady heat; but little air or water will be wanting, excepting to the kidneybeans and strawberries which you set in last month.

Forcing-houses. (2940.) Go on with the routine culture, for houses which you have begun to force; and dig and prepare the borders of the others, but it is too late for pruning or repairs.

6. Flower-garden. — Open ground department.

Proct as directed for last month, and be liberal in the use of ashes, rotten tan, litter, &c. to the roots of the more tender plants; as to beds of florists' bulbs, tender and half-hardy shrubs, as China roses, hydrangeas, &c. where such plants can be ventured in the open ground.

Routine culture. Prepare composts, manures, and such soils, and turn them over frequently. Much of the value of all composts and soils, at least for the florist, depends on their being sweet and mellow, which is only to be attained by time and frequent turnings. Attend to neatness in the application of litter, ashes, and other protecting materials.

Store-room. See that the frost is completely excluded. (1704, 1705.)

7. Flower-garden. — Hot-house department.

Glass case without artificial heat. (2686.) Attend to alpines, and florists' flowers in frames; also to annuals, as directed for last month.

Hot-beds and pits. (2578.) Go on forcing shrubs and flowers, and blowing bulbs in water; renovate by linings, where necessary. If you have begun in October to force roses, you will have them as well as bulbs in blow by the middle of the month. See to bulbs in water-glasses, and take care to keep up a succession of roses, bulbs, and most popular forcing-flowers and shrubs. (6217, to 6219.)

Green-house. (6211.) Minimum temperature 42 degrees, maximum 44 degrees, with fire-heat. Water sparingly; give air freely in good weather, and remove decayed leaves as they appear.

Dry-stove. (6176.) Minimum temperature for this month 45 degrees, maximum, with fire-heat, 50 degrees. The more severe the weather out of doors, give less water within; but give air freely in fine weather.

Bark, or moist stove. (6214.) Keep a medium heat of 55 degrees, or 58 degrees, and lessen water and air. Attend to routine culture; but the grand thing at this season is, to keep the fire-heat as regular as possible; for the ratio of increase of heat from flues, after they are heated to a certain extent, is such as often to overheat the house, and scorch or desiccate them. Mention of the many advantages of adopting steam, by which the pipes can never be heated much above 200 degrees.

8. Pleasure-ground and shrubbery.

Plant as in last month. (2077.)

Prune (2110.) in fine weather.

Protect as before. (2206.)

Routine culture. Take up leaves, and sweep them from the lawns and gravel. Repair walks, and roll them; see that water stand on no part of their surface.

Lay down turf, if you cannot help it; but this is not a good season; September and March are the best. (2101.)

Prepare for planting by trenching, digging, &c. (1870.) Rods and poles for tying up plants, and for twiners, spray or sticks for sticking climbers, as the sweet-pea, &c. (1516.)

Frill-trees. (4361.) "Complete neglected work as far as weather will permit; but if the season is severe, defer it till February. Prepare tallies, &c. Ornamental trees and shrubs. (6539, and 6245.) Finish delayed work, and attend to protecting tender sorts. See to the seeds in store, and prune only in very fine weather. Prepare tallies, labels, sticks, stakes, poles, rods, spray, fronds, and other materials of culture and management. Collect composites, earths, and manures, and turn over those you have got, so as the frost may thoroughly penetrate them.

Forest trees. (6083.) Attend to the rot-heap, seed-loft, and compost-ground; and plant, or take up, or prune only in fine weather: much depends on the season, and other circumstances. (6885.)

Plant (2077.) only in fine weather, unless thorn-hedges; or large trees of common sorts, with balls of earth.

Foll and prune (6041, and 6884.) where the trees are not for transplanting, nor of the barking sorts.

Thin out coppice-wood for poles, stakes, &c. (6012.)

Prepare for planting by the usual processes, and by fencing and draining. (6817, and 6830.)

Operate on ground and rocks, but not on build-
GENERAL INDEX.

N.B. The Numbers refer to the Paragraphs, not to the Pages, excepting in the case of the List of Authors, where they refer to the page and the year in which the Author published: in such cases the word page, and letters A. D. are prefixed.

Able-tree, populus alba, 7155.
Abercrombie, John, a British writer on gardening, page 1106. A. D. 1766.
Aberdeen nursery, 7639.
Aberdourshire, gardens of, 7639.
Abermarles, a seat in Caernarvethshire, 7014.
Ablactation (ablactatio, to wean), grafting in such a way as to wean the scion by degrees from the stock; that is, marching, 2007.
Ablaqueation (ablaqueo, a, to lay bare), the laying bare the bottom of the stem, and the princi- pal roots of fruit-trees, in order to render them more fruitful, 2102.
Abroma, polyadel. decan. and malvacceae, S. tr. E. Ind. and N. S. W., (that is, Bark-stone trees natives of the East Indies and New South Wales,) which grow freely in common garden soil, and are propagated readily by seeds and cuttings.——For the general culture of bark-stone plants, see Bark-stone.
Abrus, wild licorice, diadel. decand. and legumi- noseae, a S. tr. Jamaica, which grows in loam and peat, and is raised by cuttings, planted in sand, and plunged in the tan-bed, under a hand-glass.
Accacia, polyg. monoe. and leguminoseae, S. tr. and G. tr. Austral. E. Ind. and C. B. S. B., which grow in loam peat and sand, and are propagated by cuttings taken off at the young wood, and planted in sand under a bell-glass, and in bottom heat. Most kinds may also be propagated by large cuttings of the roots similarly treated. The H. tr. grow in similar soil, and propagate in the same manner, or by seeds.
Accena, dian. monog. and rosaceae, G. peren. C. B. S. and Austral., which grow well in loam and peat, and cuttings taken off at a joint, root freely under a hand-glass. The H. peren. will grow in common garden-soil, and are continued by cuttings.
Acalypha, monoe. monad. and euphorbiaceae, S. and H. an. E. Ind. and N. Amer, the S. an. should be sown in pots in a hot-bed, and the H. an. in the open garden. The soil for both, loam and rotten dung, or leaf-mould.
Acarnia, syngen. polyg. equal. and cynarocoecheae, a H. peren. and H. an. S. Eur. Both thrive well in common soil, and propagate by the usual means.
Acasus tellarius, or red spider, described, 7271: to destroy in the different departments of garden- ing, — see those departments.
Accelerating vegetation, operations for, 2181.
Acer,acer. polyand. malvacceae, S. tr. and H. tr. Eur. and N. Amer., which grow in any soil, and propagate by layers or seeds, and some species by cuttings.
Aceras pseudo-platanus and platanoideae, the common and several maplees, 7087. and 7089.
Aceras, gynan. monan. and orchideae, a H. peren. Eng. which thrive best in light loam and chalk, and is only to be raised by seeds.
Acetarious, plants, 2883.
Achalinia, monad. polyan. and malvacceae, S. tr. Jamaica, which grow in common soil, or in loam and peat, and cuttings root in sand under a hand-glass.
Achard, Professor Francis, page 1156; his works on gardening, A. D. 1798.
Achillea millefolli, syngen. polyg. equal. and corym- biferceae, H. peren. Eur., which grow in common soil, and are readily increased by dividing at the root.
Achas sapota, pentan. monog. and sapotaceae, S. tr. Amer. requiring a rich, loamy soil, and cuttings root in sand under a hand-glass.
Acanthaceae, in common soil, and amaranthaceae. The S. and G. tr. India, thrive in any rich soil, and cuttings root freely. The an. species should be sown in a hot-bed.
Acanthus, in common soil, and euphorbiaceae, a S. tr. Jamaica, which will grow in loam and peat, and may be increased by cuttings in sand under a bell-glass.
Acanthanda, decan. monog. and salicaceae, a S. tr. Jamaica, which may be treated like acicoton. Acanthus, syngen. polyg. frustran. and corymbiferceae, the S. and S. Amer, an. should be sown on a hot-bed, and the H. an. in the open garden.
Acricula, Virginian hemp, diece. pentan. and cheno- podeae, a H. an. N. Amer., to be treated as such.
Acorus, hypericum, hemp, and ranunculaeae, H. peren. S. Eur. of common culture.
Acerus, hexan. monog. and aroidae, H. peren. Brit. and China, marsh plants of easy culture.
Acosta, a Spanish naturalist, 39.
Acrostichum, cryptog. filices, and filices, ferns; S. and C. peren. E. and W. Ind. which grow in loam and peat, and are increased by seed or dividing the root.
Acrostichum calomelanos, 6793.
Actina, polyand. monog. and ranunculaeae, H. pe- ren. Brit. and N. Amer. of common culture.
Actinocarpus, hexan. polyg. and alismaceae, G. and H. peren. N. S. W. and Eng. aquatics, which will only thrive in water, and propagate by seeds.
Acy nations, didym. gymnos. and labiateae, H. bien. and an. Eur. of easy culture.
Adam's Lodge, of London, a fraternity of gar- deners, some account of, 7704.
Adam's Lodge, of Aberdeen, 7702.
Adam's natural theology, 7702.
Addison, Michael, a celebrated French botanist, author of Familles Des Plantes, and other works, who died in the beginning of the present century, 772.
Adansonia, sour-gourd, monadel. polyan. and mal- vacceae, a S. tr. Senegal, which grows best in rich
loam, and cuttings strike in sand, plunged in heat under a hand-glass.

Addington Place, Surrey, 7527.

Ader, duc, monad, and euphorbiaceae, a. tr. Jamaica, which may be treated like adansonia.

Adeantra, pantan. monog. and dioecem, G. tr. C. B. S. which grow in sandy peat, and the young tree which is made in cuttings, if planted in sand, will root under a bell-glass without bottom heat.

Aderathera, decan. monog. and leguminoseae, a. tr. E. Ind. which grow in loam and peat, and large cuttings with the leaves not shortened, will root in a pot of sand plunged in heat under a hand-glass.

Adiantum, maidenhair, cryptog. filices, and filices, G. and H. peren. Madeira and Brit. ferns, which grow well in loam and peat, and propagate by division of root or by seed.

Adina, tetran. monog. and globulariae, a. tr. China, of easy culture in loam and peat.

Adoxa, octan. tetrag. and saxifragae, a. H. peren. Brit. a diminutive plant, which does well in pots in good deal of soil, and is propagated by cuttings under a bell-glass in bottom heat. The S. an. and H. an. India and Amer. may be treated as tender annuals.

Aesculus, horse-chestnut, heptan. monog. and acereae, H. tr. Asia and N. Amer. which prefer light, deep soil, and sheltered situations, and are propagated by seeds or by seed.

Aesculus hippocastanum, the common horse-chestnut, 7126.

Aethionema, tetrad. silic. and cruciferae, a. H. bien. and S. W. Ind. which grow well in rich, light earth, and cuttings strike freely.

Eschymena, diadel. decan. and leguminoseae, a. tr. E. Ind. which requires rich loam, a good deal of soil, and is propagated by cuttings under a bell-glass in bottom heat. The S. an. and H. an. India and Amer. may be treated as tender annuals.

Affioli, Casimiro, his works on gardening, 1128, A. D. 1787.

African almond, brabejum stelliformifolium.

African agave, A. helen, tamphonanthus campyloides.

African fruits deserving cultivation, 6018.

African lily, — see Agapanthus.

African marigold, lagetes erecta.

African orange, A. lilly, hexan. monog. and hemicallideae, G. peren. C. B. S. which thrive in loam, and a little rotten dung, and are propagated by dividing the root, or by seed.

Ageratum campstris, garden-mushroom. See this and various other species of abies describ 4339. Culture of the garden-mushroom, 3404; what is needed is, 3404; where indigenous spawn may be collected, 3410; preserving spawn, 3412; procuring spawn artificially, 3413; propagating, 3415; methods of raising mushrooms, 3425; richness of the open air mushroom, 3425; preparing the dung, 3425; forming the bed, 3436; moulding, planting, covering the bed, 3427; culture on shelves, in the German manner, as introduced in this country, 3436; composition of bed, 3435; making, spawning, earthing, subsequent treatment, 3456; renovating old beds, 3448; growing mushrooms in pots, boxes, &c. with dung, 3455; without dung, 3443; culture in melon-beds, 3445; in hot old-beds, 3447; in pits, 3448; in dark frames, 3449; in a cellar, 3450; general details, 3452.

Agathosma, pantan. monog. and diosmeae, G. tr. C. B. S. which propagate by cuttings in sand under a bell-glass, but not plunged in heat.

Agave, hexan. monog. and bromeliacae, D. S. and peren. and N. Amer. soil, a rich loam; propagated by suckers.

Agen, General Lomer's villa at, 176.

Ageratum, syn. polg. and corymbeffereae, G. tr. requiring a light, rich soil; propagated by cuttings under a hand-glass. The H. an. is of common culture.

Aghinnias, tr. in Tyrole, 7679.

Agr. Chem., Davey's Agricultural Chemistry.

Agriculta, Dr. George Andrew, his works on gardening, page 1123. A. D. 1706.

Ageratum, syn. pantan. decan. dig. and roseacea, H. peren. Eur. and N. Amer. of easy culture.

Agrimony, — see Agrimonia.

Agrostemma, rose-campion, decan. pentag. and Caryophyllaceae, H. peren. and an. of common culture.

Agrumi, the Italian term for bitter fruits, especially the orange tribe.

Allanthus, polyg. monog. and terebintaceae, a. tr. and H. tr. E. Ind. which grow in common soil, and are propagated by cuttings of the roots.

Almsfield, a seat in East Lothian, 7619.

Air, its use and utility in heat.

Air-plant, — see Arideae.

Aira, hair-grass, trian. dig. and gramineae, H. peren. and an. of common culture.

Airthistle Castle, near Stirling, 364.

Aiton, monad. octan. and meliaceae, G. tr. an. C. B. S. soil, sandy loam and peat; propagated by cuttings in sandy wood, in sand, under a bell-glass, and plunged in heat. Avoid planting too close, and wipe the glass frequently, as they are apt to damp off.

Aizoon, di-pentag. and ficoidea, a. tr. and bien. C. B. S. and Eur. succulents, which grow in lime-rubbish, and propagate readily.

Akeee-tree, blighia sapida. 

Alamannii, Luigi, his works on gardening, page 1128.

Alangium, polyan. monog. and myrtaceae, a. tr. E. Ind. soil, loam, and peat; propagated by cuttings, in sand, in a hand-glass in heat.

Alaternus, rhamnus alaternus.

Albojico, J. H. his works on gardening, page 1125.

A. D. 1755.

Albica, hexan. monog. and asphodeeleae, G. peren. C. B. S. which require peat soil and shady situation, and propagated by offsets from the roots.

Alcarias, monog. and boragineae, H. peren.

Alcea, syn. parthenocarya, and corymbiferae, a. G. an. Mexico, of easy culture.

Alcoves, 1510.

Aldbury Place, Surrey, 7527.

Aldea, pantan. monog. and boraginaceae, a. H. peren.

A. D. 1706.

Alder — see Albus.

Aldiefer, Pantan. monog. and boraginaceae, a. H. peren. Magellan, of common culture.

Alfons — see Albus.

Alderley Park, Cheshire, 7590.

Aldworth Hall, Yorkshire, 7582.

Aletris, hexan. monog. and hemicallideae, H. peren. which require a peat soil and shady situation, and propagated by offsets from the roots.

Aleurites, monog. and euphorbiaceae, a. tr. Society, of a rich loam, rich cuttings, with their leaves on, strike in sand, under a hand-glass.

Alexanders — see Smyrnium.

Alexandrian laurel, ruscus racemosus.

Allisma, water-plantain, hexan. polg. and alismaceae, H. peren. marsh plants, and aquatics of easy culture.

Alison, the Rev. A. W., his Analysis of the Principles of Design, 7165—7162.

Allamanda, pantan. monog. and apocynaceae, a. tr. Guittem, with a rich loam; cuttings strike freely in moist peat.
Allantodia, cryptogam, filices, and filiceæ, a G. peren. Madeira; a fern; soil, loam and peat; and propagation by dividing the root or seed.

Allium, cyananthum, sect. in yeast, 7620.

Allicaceae plants, 3810.

Alligator-pear, laurus persica, 5977.

Allium, trit., 3811, by cytogenetic, H. peren. to which, in common soil; and cuttings root readily under a glass-house.

Allium, garlic, hexan. monog. and asphodelée, H. peren. and biennial, requiring of easy culture.

Allium acuminatum, the shallot, 3845.

Allium cepa, the common onion, 3830.

Allium porrum, the leek, 3841.

Allium sativum, the garlic, 3841.

Allium schoenoprasum, the chive, 3838.

Allium schoenoprasum, the rocambole, 3832.

Allium stylopestis Calycanthi, is difficult.

Allispacea, myrtus pimienta.

Almond,—see Amygdalus.

Anthus, alder, monoe. tetran. and ameanteece, H. tr. Eur. and N. Amer. of common culture, propagated by seeds.

Anthus glutinosus, the common alder, 7132.

Aloe, hexan. monog. and homoeeoloidæ, D. S. and G. tr. and peren. C. B. S. which grow best in sandy loam, with lime-rubish or gravel, and are propagated by suckers, or leaves stripped off, and left exposed shallow in, or laid on the surface of a pot of moil.

Aloïsia, didyn. angios. and solanææ, G. tr. S. Amer. which grow best in light soil, and are increased by seeds or cuttings.

Alosia, didyn. angios. and verbenaceæ, a G. tr. Chili, which grows in light, rich soil, and increased by cuttings.

Alpinia, monoe. monog. and scitamineæ, S. per. W. and E. Ind. redcy or marsh hot-house plants of common culture.

Astrémmea, hexan. monog. and asphodelæ, S. and G. peren. S. Amer. which thrive in sandy loam, and peat or vegetable earth, and increase by seeds or dividing the same, as light as is given to flower, unless the roots are put into a state of rest, by withholding water till the shoots are quite dried up; then give a good watering, and put it in a moist heat, and it will flower abundantly. (Sweet.)

Astrémmea salisilia, the edible astrémmea, 6030.

Aston Grove, Nottinghamshire, 7576.

Atterbury, Pomological Society of, their annals, page 1127. A.D. 1810.

Aulacanthera, pentan. monog. and amaranthaceæ, a S. Amer. S. Amer. and a G. tr. E. Ind. monog., S. Amer. soil, light and rich, and cuttings root freely in the shade.

Althea, marsh-mallow, monad. poly. and malva.æ, S. peren. and biennial and H. peren. tr. and an. cult. of common culture.

Althea frutex, hibiscus syriacus.

Althaea rosea, a G. tr. Northamptonshire, 7590.

Alissyum, mugwort-tet. tetrad. silic. and cruciferæ, a F. tr. and H. tr. peren. and an. Eur. of ease culture in common soil, and readily increased by propagation.

Amarillis, hexan. monog. and amaryllideæ, S. and H. peren. Eur. Amer. and Afr. bulbs of common culture: some may be treated as aquatics, 9683, 9637.

Amaranthus, garden and mangetout, 7407; their gardens and management, 7438.

Amblystegiæ, fistullæ, homoeo-ethypnyæ, 7612.

Ambrosia, monoe. pentan. and corymbiferæ, H. an. of common culture.

Amelius, syngen. polyg. super. and corymbiferæ, a G. tr. C. B. S. soil, loam and peat, and cuttings root freely under a glass; and H. peren. which grow in common soil, and cuttings root freely under a hand-glass.

American books on gardening, 7699.

American cowslip, dodecatheon meadia.

American garden, how to compose the soil, 6585; or are arranged, 6152.

American shrubs, 6562; culture, 6568; final situation, 6569.

Ameriunum, diadel. decan. and leguminosæ, S. tr. W. Ind. requiring a light loam; and cuttings, not deprived of their leaves, root freely under a hand-glass in a warm situation.

Amethystea, dian. monog. and labiateæ, a H. an. Silene of common culture.

Ammannia tetran. monog. and salicaceæ, a S. an. and H. an. W. and E. Ind. of easy culture.

Amomum, monan. monog. and seintaneeæ, S. peren. Siecle, very rare, many plants.

Amorphophallus, handi. indigo, diadel. decan. and leguminosæ, F. and H. tr. Amer. which grow in common soil, and increase by cuttings planted in autumn, in a sheltered situation.

Amystill Park, Bedfordshire, 7549.

Ampton Hall, Suffolk, 7532.

Anemone, pentan. monog. and acynerææ, H. peren. A. N. Amer. of common culture, which grow in common soil, and are increased by cuttings or dividing at the root.

Anemomyal, alp. icos., monog. and rosaceæ, a G. tr. and H. tr. Persia and Eur. requiring rich loam, and which may be propagated by seeds, layers, grafting, &c.

Anemomyal communis and amara, the sweet and bitter almond, 4545.

Anemomyal persica, the peach-tree, 4545; flat peach of China, 4545.

Anemomyal var. nectarina, the nectarine-tree, 4547; to force the peach and nectarine, 3063.

Anemomyal, octan. monog. and terebinthaceæ, S. tr. S. Amer. soil, loam and peat, and cuttings root freely in sand; under a hand-glass.

Anabasis, pentan. digy. and chenopodiææ, a G. tr. Spain, which grows well in loam and peat, and cuttings root in sand under a hand-glass without bottoming.

Anacampseros, dodecan. monog. and portulacaceææ, G. tr. and peren. C. B. S. succulent which grow in sand, and lime-rubish, and cuttings root readily in similar soil.

Anacardium, cashew-nut, eneac. monog. and terebinthaceææ, a S. tr. India, soil a light loam, and cuttings from ripened wood, not deprived of their leaves, will root in sand under a hand-glass.

Anacysus, syngen. polyg. super. and corymbiferææ, H. an. of common culture.

Anagalish, pinnemarket, pantan. monog. and primumaceææ, a G. an. and biennial and H. peren. and an. Eur. all of easy culture, increased either by seeds or cuttings.

Anagryis, bean-trellis, decan. monog. and leguminosææ, a G. and F. tr. Spain and Tenerife, soil loam and peat, and cuttings will root in sand under a hand-glass.

Anarrhinum, didyn. angios. and scrophularinæææ, a H. bien. of common culture, and of Jericho, tetrad. silic. and cruciferææ, H. peren. Levant, which will grow in common soil, and cuttings under a hand-glass root freely.

Anchoveys-persis, gross califorina, 5079.

Anchusa, bugloss, pentan. monog. and boraginaceææ, G. and H. bien. and peren. Eur. and C. B. S. which grow freely in common soil, and are increased by cuttings or seeds.

Andersonia, pentan. monog. and esclerideæ, a G. tr. N. Holl. which grows freely in peat soil with the pots well drained, and not overwatered; young tops more into cuttings root in sand under a bell-glass.

Andraeæ, bastard orpine, monoe. gynan. and euphorbiaceææ, a H. an. Italian of common culture.

Andreas, Mr. Isaac, an eminent grower of the pine-apple at Lambeth, 2712.

Andreas, Henry, a British writer on gardening, page 1188. A.D. 1778.

Andromeda, decan. monog. and ericeææ, S. G. and H. tr. N. Amer. E. Ind. and Eur. which prefer peaty loam, and cuttings strike in sand under bells or hand-glasses; but the hardy sorts make plants more rapidly by layers, 6565.

Andropogon, polyg. monoe. and gramineææ, S. and G. tr. and H. peren. E. Ind. and Eur. grasses of easy culture.

Androsace, pentan. monog. and primulaceææ, H. peren. and an. Eur. which thrive best in small pots in turfy loam and peat, the pots being well drained; they are increased by seeds, or dividing at the root.

Anthemis, annual, dig. and umbelliferce, a H. peren. and an. Eur. of common culture, and propagated by seed.

Anthemis, annual, dig. and umbelliferce, H. peren. and. Eur. and N. Amer. which grow in loam rather light and rich than heavy, and increase by dividing the root or by seeds.

Anthemis coronaria, and hortensis, the common garden anemone, 6275.

Anethum, dill, pentan. dig. and umbelliferce, a H. peren. and an. Eur. of common culture, and propagated by seed.

Anethum funiculum, the common fennel, 4097.

Anethum gravedon's, the common dill, 4103.

Anethum, dill, pentan. dig. and umbelliferce, H. peren. and. N. and Amer. which grow in loamy deep soil, and are increased by seeds.

Angelica, Anisum, and anisum-tree, anisum, and umbelliferce, H. peren. and. N. and Amer. which grow in loamy deep soil, and are increased by seeds.

Angelica archangelica, the garden angelica, 4216.

Angelica tree, aralia spinosa.

Angelica, and Echium, gardens and residences of, 7065.

Angrun de Rieuvenewe, a Fench writer on gardening, page 1117. A. D. 1712.

Anguina, monos dium and cucurbitacese a S. peren. Carthageana, soil light and rich; propagation by cuttings or seeds.

Angus, or Forfarshire, gardens and residences of, 7065.

Anigozanthos, hexan. monog. and hemodoraecae, Gr. tr. N. Holl, which grows in loam and peat, requires a good deal of water, and is increased by dividing at the root.

Anise, pimplina anisum.

Aniseed-tree, — see Illycum.

Anisopelos, didyn. saccus, and labiatense, a S. an.

Ann. E. Ind. of the usual culture.

Annona, bastard-apple, polyan. and annonaceae, S. tr. W. Ind. and S. Amer. requiring a rich loam; and ripened cuttings with the leaves unshortened, will root in sand, under a glass in a moist heat.

Annuus, plants such as are of one year's duration, and are therefore raised annually from seeds ripened the previous year. There are some exceptions in the cases of rare plants which do not seed freely; or where particular varieties are to be preserved. In these cases propagating by cuttings or layers is the best method.

Annuals, bark-stove or hot-house, their culture, 6794, 6795.

Annuals, dry-stove, 6688.

Annuals, frame, their culture, 6596.

Annuals, green-house, their culture, 6600.

Annuals, half hardy, their enumeration, 6512; culture, 6513.

Annuals, hardy, adapted for border-flowers, 6506; their culture, 6507.

Anomatheca, trian. monog. and iridea, a G. peren. of the bulb of the spring garlic family.

Anson Hall, Warwickshire, 7571.

Ant, — see Formica.

Anthemis, chamomille, syngon, polyg. super. and corymbiferce, a G. peren. and H. peren. and an. Eur. and China, of easy culture, and propagated by seeds, cuttings or dividing at the root.

Anthemis artemisiaefolia, the Chinese chrysanthemum, 7170.

Anthemis nobilis, the common chamomille, 4235.

Anthericum, hexan. monog. and asphodelaceae, G. tr. peren. of the bulb of the sandly loam, with the pots well drained; the bulbous kinds should have no water when not in a growing state; the shrubby sorts root from cuttings, and most of the species produce seeds.

Anthoceros, didyn. angios. and solaneceae, a G. tr. N. Holl, which grows in loam and peat, and cuttings root readily under a bell-glass in sand.

Antholyza, triand. monog. and iridea, G. and H. peren. of the bulb of the sandly loam, C. S. burkened, and cuttings root readily from cuttings.

Antennaria, amber-tree, diex. tetran. and ru- mineceae, a G. tr. C. B. S. which grows well in loam and peat, and strikes readily from cuttings.

Anthotheca, moro. dig. and digitales, H. peren. Brit. and Morocco, of the easiest culture.
Aristolochia, a palace and gardens in Spain, 294.
Araucaria, dioec. monad. and conifereæ, G. tr. C. Amer. 
Australis, Norf. which grow in sand, loam and peat, "and cuttings may be rooted, though with difficulty, taken off at a joint in ripened wood, and planted in a pot of sand under a hand-glass, but not best." (Sweet.)
Arborium of the Hackney nursery, 7356.
Arbor vitae, — see Thuja.
Arbutusstrawberry tree, decan. monog. and eri- 
Arctium, G. tr. Eur. which grow best in sandy 
Arduina, — see Angelica.
Aristida, — see Aristi.
Argyleshire, 209.
Ardenne, 992.
Arctium, G. tr. Eur. which grow best in sandy 
Arduina, — see Angelica.
Artemisia, — see Apium.
Arran, gardens of, 7520.
Arundel Castle, 7532.
Arizona, ararabacca, dioec. monog. and aristol- 
Arctotis, syngen. polyg. nee, and corybim- 
Arctizia, birth-wort, gynan. hexan. and aristolo- 
Artocarpus, tree, Eur. which thrive well in common soil, and are increased by propagating by the roots; and the woody sorts by cuttings.
Artichokes, - see Cynara.
Artidi jardiner, 186.
Artocarpus, the bread-fruit tree, monog. monog. and sind. S. tr. S. Sea Ind. and Ind. which thrive well in light soil, and propagate readily by cuttings, with their leaves entire.
Arctopus, polyg. dioec. and umbellifereæ, a. peren. 
Aristea, — see Arista.
Arun, monog. and asphodelea?, G. peren. 
Armeria, — see Armeria.
Arsenious, — see Arsenious.
Arsenium, monog. and asphodelea?, G. peren. 
Artemisia, — see Artemisia.
Artemisia, — see Artemisia.
Arnica, — see Arnica.
Arnold, Richard, a British writer on gardening, 
Arnold, see Arno’s.
Arno’s, see Arno’s.
Arnos, see Arnos.

Bane-berry (Baan, Sax. a murderer, and berry), actea spicata.

Banfshire, gardens of, 7690.

Banksia, Euc., 7690.  
— decam., 7690.  
— repand malpighiaceae, T. tr.  
— Amer. and W. Ind. which grow well in sandy loam, and cuttings of ripe wood root freely under a sandy soil.

Banquete, tetran. monog. and proteaceae, G. tr. New Holi, soil one third peat, one third loam, and one third sand, with the pass well drained, and the plant never let want of water, and seldom recover. Cuttings must be well ripened before they are taken off, cut at a joint, and planted in beds of sand without shortening the leaves; cover with hand-glasses, but do not plunge in heat.

Banyan-tree (priest’s tree, Ind.), fucus religious.

Barbadoes, Basilea, decan. monog. and leguminosae, H. peren.  
— Amer. which grow well in good garden soil, and are propagated by seeds, or (though slowly) by dividing the root; and propagated by seeds.

Barbados bastard-cedar, babrona guazuma.

Barbadoes cherry, see Malpighia.

Barbara, winter-cress, tetrad. siliq. and crucifereae, H. peren. Brit. which will grow in any soil, and may be propagated by seeds, or by dividing the plant.

Barbarea vulgaris, the common winter-cress, 4060.

Barberry (barb, a beard, and berry), see Berberis.

Barreille, Giuseppe, his work on fungi, page 1138.

Bargapark, Ayeshire, 7687.

Bark for the use of tanners, trees from which it is usually or may be obtained, 632, and 4754.

Bark-stores, how to manage for horticultural purposes, 1792.

Bark-store, or moist-stove; a hot-house in which the mass of bark, earth, sand, or other materials in which the pots containing the plants are plunged, or the plants themselves planted, is heated from below; or by the fermentation of the materials, as well as by the atmosphere of the house.

Bark-stove, used in horticulture, its construction and management, — see Pine-stove.

Bark-stove, used in barke, see Dividing for growing or flowering plants, 6177.

Bark-stove, used in floriculture, its general management, 6214.

Bark-stove, used in floriculture for propagation, its culture, 1629.

Barking-irons, for the garden, 1541; for the forest, 1343.

Barleria, didyn. angios, T. tr. bien. and G. peren.  
— India and Amer. all which grow in loam and peat, with a little rotten dung, and cuttings root freely under a hand-glass.

Barley, — see Hordeum.

Barmeath, a seat in Lowth, 7694.

Barnarrow House, Drum, 7694.

Barnbougle, the name assumed by Sir John Hill, as an author on British gardening, page 1105.

Barnsley Park, Gloucestershire, 7695.

Barnton, a seat in Midlothian, 360.

Barometer, as a means of foreknowing the weather, 1429.

Baron Hill, a seat in Anglesea, 7693.

Baron of Court, a seat in Tyrone, 7679.

Bazin, pennant. monog. and diosmea, G. tr.  
— C. B. S. which grow well in sandy peat, and cuttings of ripened wood root readily in sand under a bell-glass.

Barrenwort, — see Epimedium.

Barringtonia, monad. polyand. and myrticeae, T. S. tr. F. Ind. a very fine plant, scarce, and supported difficult to manage; soil two thirds loam and one third peat kept moist, and cuttings of ripe wood taken off at a joint, and put in a pot of sand, and kept a little moist, without shortening the leaves, will root readily. (Sweet.)

Barrington Hall, Gloucestershire, 7562.

Barrow, different sorts of, 1441.

Barrow, wateringen, 1450.

Barruel-Bouwvert, his works on gardening, page 1119. A.D. 1792.

Barron, a warm place, or pasture.

Bartholina, gyan. monan. and orchideae, G. peren.  
— C. B. S. which thrives best in sandy loam and peat, with a little water when not in a growing state; it is propagated by dividing the root.

Barton (Sax.), a backside or backlying field.

Bathorne House, Durham, 7584.

Bartonia, lcos. monog. and rosaceae, G. bien. Missour. and del., a very common plant, and propagated by seeds.

Bartsia, tetrad. siliq. and scruphulariaceae, H. peren.  
— Amer. which are rather difficult to preserve, and require a very sandy kind of peat earth; or to be planted in pots of the soil of the common sand, and kept moist; and H. an. Brit. which grow freely in a sandy soil.

Bass-rock, sedes lutea.

Basella, pennant. trig. and chenopoduea, S. bien. and an. of common culture.

Basella altilis, see Spinacia, as a spinach plants, 4238.

Basil (Basil, a town in Switzerland), — see Ocumum.

Bass mats, (from the Russian bastard-bark), cloth of liver, or bastard bark, used in gardening, 1506.

Bassia, dedoe. monog. and scapeote, S. tr. E. Indies, which grow freely in light loam, or loam and peat; and open cuttings strike under a hand-glass in sand.

Bassingham Hall, Durham, 7584.

Bastard balm, — see Mentis.

Bastard cabbage-tree, — see Geoffroya.

Bastard cedar, — see Cedrela.

Bastard harte’s ear, phyllis nobla.

Bastard indigo, — see Amorpha.

Bastard lupine, — see Lupinaster.

Bastard mangetuce, — see Cameraria.

Bastard origan, — see Andrychus.

Bastard piperment, centunculium minimus.

Bastard toad-flax, — see Thesium.

Bastard vervain, — see Stachyurapheta.

Bastard wallflower, — see Zinnia.

Bastard, William, Esq. a British writer on gardening, page 1108. A.D. 1777.

Bastien, Jean Francois, his works on gardening, page 1125. A.D. 1792.

Batchia, pennant. monog. and boragineae, H. peren.  
— Amer. which grow well in common soil, and are increased by seeds, or by dividing the roots.

Bauena, polyan. dig. and estlinean, G. tr. N. S. W. which grow in loam and peat, and cuttings root readily in the same soil under a bell-glass.

Bauhinia, mountain ebony, pennant. monog. and leguminosae, S. tr. E. and W. Ind. mostly climbers which thrive well in light loam, and cuttings between old and young, do well under a bell-glass in sand, in a moist heat.

Bauman, F. G., his works on gardening, page 1119. A.D. 1785.

Baven, fragots of branches and spray, with their ends untrimmed.

Bavis Mount, a seat in Hampshire, 7592.

Bawd-moneyn, aethamathianicum.

Bay, — see Laurus.

Bayham Abbey, a seat in Sussex, 7581.

Baylin, Giles Augustin, his works on gardening, page 1104. A.D. 1769.

Beale, Dr. John, a British author on gardening, page 1101. A.D. 1666.

Beale, John, a British author on gardening, page 1160. A.D. 1657.

Bean, — see Vicia.

Bean-tree, — see Zygophyllum.

Bean-trefoil, menyanthes trifolata, — see Menyanthes.

Bearbird, — see Convolvulus.

Bear’s breast, — see Acanthus.

Bear’s ear, sanicle, — see Sanicula.

Bearberry, arbutus uva-ursi.

Beaudesart, a seat in Staffordshire, 7570.

Beaufortia, polyadelph. isocan. and myrticeae, G. tr.  
— Ind. soil, twothirds peat and one third sandy loam, and cuttings from nearly ripened wood, strike root freely in sand under a bell-glass.

Beaumanor, a seat in Leicester, 7573.

Beaumont, Sir Harry, a name assumed by Mr. Spence, and affixed to letters from China, translated from those of the Chinese, and descriptive of the emperor’s gardens, 470.

Beaumont, Simon de, a distinguished citizen of Holland in the 17th century, a great encourager of botanical gardening, who had a fine garden at Bevering, 132.

Beaumont Lodge, Berkshire, 7561.

Beauvoir, his work on gardening, page 1122. A.D. 1829.

Beauty, that property in objects by which they are
recommended to the power or faculty of taste; the reverse of ugliness; the primary, or most general object of love or admiration. (Jeffrey, in Supp. Encyc. Brit.) That which gives pleasure to the mind in objects of sense. (M. A. Schimmel-pensich, chap. 4.)

Though, in the common colloquial acceptation of the term beauty, it is applied only to such objects as delight the senses of sight or hearing; yet, in the strict and literal sense of the word, a fine view, a harmonious concert, the perfume of a rose, or the taste of an amanu, are each possessed of beauty. The authors quoted, and also Alison, Stewart, and Knight, have discussed the subject of beauty in a clear and satisfactory manner. It appears that the true error of preceding writers on the subject, consisted in supposing that there was only one kind of beauty; whereas, there are many kinds, though sometimes much more general and universal than others. Nothing but mind can either please or disgust mind; and therefore the beauty that we see in objects depends, as D’Alembert has observed, on what is within our selves. Man is possessed of the origin of every taste and refined enjoyment naturally; but every one of these, from the lowest sense to the highest, requires a cultivation before it become capable of conferring much intellectual gratification. Though in the nature of things, therefore, there may be an absolute or universal beauty; yet, practically, beauty may be said to be relative to the state of man in different countries and ages, and in different degrees of civilization and refinement. Fashion, the more prevailing mode of the day, will by the great number of persons, always be esteemed the true criterion of beauty.

dens in the East Indies, 401. Benham House, Berks, 7591. Benigni, Fortunato, his work on gardening, page 1128. A. D. 1813. Benjamin-tree, laurus benzoine. Bennett, General Von, a native of Germany, and general of cavalry in the Russian service; a warm patron of arts and sciences, who had a fine seat and botanical garden near Wilna, which was burnt to the ground and destroyed in the retreat of 1812, 283. Bent-grass, — see Agrostis. Bentley, Francis, Middleshire, 7521. Bents, bulrushes, — see Juncus. Beerardia, syngy. polyg. equal. and cynarococ-
phex, H. peren. Italy, of common culture. Berberis, Berberis, bergamot, and berberidoe, H. tr. Eur. and Amer. of robust-growth and easy culture, propagated by suckers and seeds. Berberis vulgaris, the common barberry, 6581. Bercesa, (erd. arch.), an arch or bower, formed in horticulture and arboriculture as a place of repose, — see Arbor. Bercheys, syngy. polyg. frut. G. tr. and bien. C. C. 6. Etc, grows freely in loam and peat, and root readily in common earth under a hand-
gated by seeds. Beta cicla, the white beet, a spinaceous plant, 5719. It is from the roots of this last species that the French of Germany, in former times, obtained sugar rich so much success during the late war. The follow-
ing was the ordinary process: — Reduce the roots to a pulp, by passing them between two rough cylinders; put the pulp in bags and press out the liquor it contains; boil this liquor, precipitate the saccharine matter by quick-lime; pour off the liquor; add to the residuum a solution of sulphuric acid, and boil again; the lime uniting with the acid, is got rid of by straining; and the
liquor may then be gently evaporated, or left to granulate slowly, after which it is ready for undergoin the common process of refining raw sugars.

Beta maritima, a native plant which may be used as an excellent, Beta vulgaris, the common red beet, 3731.

Betonica, betony, didyin. gymnos. and labiatea, H. peren. Fam. of common culture. Betonica officinalis, a tea-plant, 4319.

Betony, — see Betonica.

Betula, birch, monceq. polyum. and amantaece, H. tr. of many American sorts prefer bog-earth and moisture, and are propagated by suckers or layers, and some curious sorts by grafting or budding.

Betula alba, and other species cultivated as timber trees, 7108. to 7111.

Bevel, or bevel-square, an instrument made use of by carpenters and joiners, and also in gardening for the adjusting of angles.

Bib. Bank, bibliotheca bankiana.

Bickham, George, a British writer on gardening, page 1104. A. D. 1750.

Bickton, a seat in Devonshire, 7600.

Biedens, syngen. polyg. equial. and corymbiferean, a s. an. H. peren. and H. an. E. ind. and S. Amer. the annual species may be treated as tender and hard-halfy annuals; they prefer a moist situation and light soil. The perennials may be kept in pots in similar soil, and propagated by dividing the plant.

Bidle, M. — his writings on gardening, page 1179. A. D. 1773.

Biennial plants, such as are of two years’ duration in their natural circumstances; but by culture, and especially by pinching off the flowers as they appear, many of these may be rendered triennial or of still longer duration. Many exotics, which are annuals and biennials in their native countries, are perennials in our stores.

Biennials, hardy, 6594.

Biennials, frame, 6595.

Biennials, green-house, 6600.

Biennials, green-house, 6602.

Bignonia, trumpet-flower, didyin. angios. and big-noiaceae, S. and G. tr. S. Amer. and China, some are climbers, and all grow well in loam and peat, and in young shoots root readily, either in mould or sand, under a hand-glass in heat. The H. tr. are climbers, and grow well in common soil, and are increased by cuttings from the young wood or roots.

Bilham House, Yorkshire, 7582.

Bill, an edge-tool, at the end of a stake or handle; if flat, it is called a hand-hill, and when long, a hedging or hedgebill, — see Hedgebill.

Billardiera, apple-berry, pantan. monog. and pitto-poreae, G. tr. Austral. climbers, which thrive well in green-house, and cuttings root readily in sand under a bell-glass. Billlet (billett Dr.), a tree or log of wood, cut up for billett-wood.

Biscutella, buckler-mustard, tetrad. silly. and cruciferiae, a F. tr. and H. peren. and an. Eur. of common culture.

Biscutella, hatchet, diabel, diadal. decem. and legumi-noseae, H. an. S. Eur. of common culture. Bishop’s Court, a seat in Kildare, 7637.

Birch’s white Path, — see Pathum.

Bilston House, the seat of Addison, in Warwick-shire, 7571.

Bindweed, — see Convolvulus.

Birmania, (dey), a pond or staw for the keeping and feeding of fish.

Birch, — see Betula.

Bird, — see Capilum. Birds, or feathered enemies of gardens, 2283; how to destroy, 2280.

Bird’s eye, primula farinosa. Bird’s foot, — see Ornitho.

Birdsfoot-trefoil, — see Lotus.

Birds, a seat in Yorkshire, 7538.

Bird-wort, — see Aristolochia.

Bitter-sweet, solanum dulcamara.

Bitter vetch, — see Orobus.

Bixa, anonna, polyan. monog. and tiliaceae, a S. tr. W. Canar. which grows to a large plant before it flowers, and therefore cuttings should be taken from flowering plants, in order that they may flower soon: they root freely under a hand-glass in sand, and the plants grow well in loam and peat.

Blackberry; in England, the berries of the bramble are so numerous; and in Scotland, those of the black currant.

Black brony, — see Tamus.

Black saltwort, glau maritima.

Black anemone, humming-pantaece.

Blackmore Park, Worcestire, 7556.

Blackweel, Elizabeth, widow of Dr. Blackwell, who died in 1757, of cause of a curious herb, containing 500 cuts of the useful plants.

Bladder-nut, — see Staphylea.

Bladder-ennas, — see Colutea.

Blade, (blad Dr.), a leaf.

Blaria, tetran. monog. and ericeae, G. tr. C. B. S. which thrive only in sandy peat, and young cuttings will root in sand under a bell-glass, or in a close frame in a shady situation.

Blair Adam, a seat in Kinross-shire, 7634.

Blair Drummond, the seat of the late Lord Kames, and now the seat of Mr. Home Drummond, in Perthsire, 7636.

Blair House, or Blair Athol, a seat of the Duke of Athol, in Perthshire, 7636.

Blair Castle, Gloucestshire, 7564.

Blake, Stephen, a British writer on gardening, page 1101. A. D. 1664.

Blakes, dodeq. monog. and melastomeae, a S. tr. Jamaica, which thrives well in peat and loam, and requires a good deal of water; cuttings require to be quite ripe, otherwise they rot; planted in sand in moist heat under a hand-glass, they root freely.

Blakie, Thomas, Esq. of Beechwood, near Edin-burgh, 1750.

Blanching (whitening), a process for depriving plants of part of their bitter qualities, 2156.

Blanching-pots, 1617.

Blandfordia, behavn. monog. and hemicalloidae, G. peren. N. S. W. which grow in sandy loam and peat, and are propagated by suckers or seeds.

Blarney Castle, in Ireland, 368.

Blat, plants, and especially the cereal grasses, are said to be blasted when the seeds or ears are lank and thin, — see Vegetable Pathology.

Blattia, the black beetle, or the black-road, 2239.

Blchum, didyin. angios. and acanthaeceae, a S. peren. W. Ind. which grows well in a rich light soil, and cuttings root freely under a hand-glass in heat.

Blchum, cryptoc. filices, and filices, G. and H. peren. C. B. S. Eur. and N. Amer. ferns, which grow in loam and peat, and are increased by dividing at the root or seeds.

Blondon Hall, Kent, 7537.

Blechen, a seat in Oxfordshire, 7559.

Blessingdon Gardens, situated in the county of Dublin, formerly of some note, 367.

Bletia, gynan. monan. and orchideae, S. peren. China and W. Ind. which grow well in sandy loam and peat, and are readily propagated by dividing at the root.

Blickling Hall, Norfolk, 7554.

Blighia, scone-trees, octan. monog. and sapindaeae, a S. tr. 5975.

Bligh, a common term for injuries received by the vegetable kingdom when in a state of growth, which cannot be referred to any obvious or certain cause, and coming suddenly is said to give them the appearance of being blighted or blasted, — see Blight. Blith, — see Blight.

Blith, — see Blight.

Blith, Walter, 182; a British writer on gardening, page 1100. A. D. 1649.

Bilston Hall, Staffordshire, 7570.

Boboli gardusce, at Florence, 83. Boc. mus., Museo di Plante rare di Don Paolo Bocconia, tree-celandina, dodeq. monog. and papaveraceae, a S. tr. Ind. which grows well in sandy loam, and ripens seeds plentifully; and a H. tr. monog. which grows well in rich soil, and is propagated by dividing the roots.

Bockmann, A. D., his work on gardening, page 1129 to 1137.

Bodach, a seat in Montgomeryshire, 7611.

Bodorgan, a seat in Anglesea, 7093.

Bocineria, monog. tetradi. and urticeae, a G. tr. Canar, which thrives well in loam and peat, and cuttings root freely in the same kind of soil.
Bramborough House, Cheshire, 7590.

Bramham Park, Yorkshire, 7582.

Bramkoti, Don Giulio, his works on gardening, page 1128.

Bramhall Hall, a seat in Cheshire, 7590.

Bramshill, a seat in Hampshire, 7594.

Brass, plate, 4063.

Brassica, gynan. monan. and orchideae, a S. peren.

Brassica oleracea var. capitata, the white cabbage, 3557.

Brassica oleracea var. gynan. oracea, 3555.

Brassica oleracea var. s. sabauda, the Savoy cabbage, 3513.

Brassica oleracea var. c. sabauda subvar. g., the Brussels sprouts, 3522.

Brassica oleracea var. s. sabauda subvar. t., the broccoli, 3555.

Brassica oleracea var. c. napobrassica, turnip-rooted cabbage, 3529.

Brassicapa, rape, used as a salad plant in gardens, and grown in agriculture for food for deep, and for the seed to be pressed for its oil, 4028.

Brassica rapa, turnip, 3603.

Brassica erucia, a salad plant, 4063.

Breadfruit, see Artocarpus.

Breachin Castle, a seat in Forfarshire.

Brecket Hall, Hertfordshire, 7544.

Breconshire, gardens of, 7632.

Breidtobach, Ph. Fr. his works on gardening, page 1126. A. D. 1806.

Breby Park, a seat in Derbyshire, 7574.

Breconshire, M. — de la, his works on gardening, page 1119. A. D. 1783.

Breckenhead, bury, a seat in Hertfordshire, 7544.

Bride, his works on gardening, page 1126. A. D. 1758.

Bridgeman, a landscape-gardener of eminence in the early part of the 18th century, 942.

Bridges, different kinds of, used in gardening, 1762.

British authors on gardening, 7586.

Briza, quaking-grass, trian. dig. and gramineae, a H. peren. and an. of the easiest culture, 7587.

Bro. Jam., the Civil and Natural History of Jamaica, by Patn. Browne.

Broadlands, a seat in Hampshire, 7594.

Brockier, Francesco, his work on gardening, page 1126. A. D. 1777.

Brokeley Hall, Yorkshire, 7582.

Bredon Park, in Queen's Country, 7659.

Broo, Philip, le, M. A. a British writer on gardening, page 1109. A. D. 1786.

Brodiaea, hexan. monoc. and hemerocallideae, G. peren. Georgia, which grow well in sand and peat, keep moist, and are propagated by dividing the root like agapanthus.

Brice House, in Hampshire, 7638.

Bromborough House, 7590.

Brom-grass, — see Bromus.

Bromelia, hexan. monoc. and bromeliaceae, S. tr. natives of South America and the West Indies, all of which grow well in two thirds good fresh loam, one third leaf mould or rotten dung, and as much sand as will prevent the mixture from being and compact, with watering. A warm, and rather moist atmosphere is required to grow the fruiting sort to any size; but they are otherwise very easily grown. Most of the species bear that peculiar production called a crown on the summit of their fruit, by which, or by suckers, they are usually propagated.

Bromus, the genus, the common pine-apple; its history and varieties, 4784; its general culture, 2997; preferable varieties, 2998; soil, 2790; artific. heat, 2794; cultivation, 2718; succession department, 2753; fruiting department, 2792; general directions common to the three departments, 2842; insects, 2506; compendium of a course of culture, 2917; recent improvements by Knight, Marsland, &c. 2994.

Brompton agricultural nursery, Middlesex, 7518.

Brompton farm nursery, Middlesex, 7518.

Bromus, brome-grass, trian. dig. and gramineae, H. peren. tr. and an. Eur. of the easiest culture.

Brookline, veronica beccabunga.

Brookshaw, George, a British gardener, page 1114. A. D. 1817.

Brookes, see Samuelus.

Broom, — see Spartium.

Broom-rape, — see Orobanche.

Broome, John, 3rd, pulmon. dicot. and .......

Broom, S. tr. Jam. soil, a light loam; propagation by large old cuttings not divested of their leaves, in a pot of sand under a hand-glass in a moist heat.

Brossard, Davy, or David, a French writer on gardening, page 1115. A. D. 1595.

Brosope, peren. monegas and etricae, a S. tr. S. Amer. which grows in peat and sand, and young cuttings will root in the same mixture under a bell-glass on gentle heat.

Brotores, syngen. poly. segr. and cynarocophalaen, a H. peren. S. Amer. which will grow in common loam, and is propagated by dividing the root.

Broughton Hall, Staffordshire, 7570.

Broughton House, Kircubrightshire, 7625.

Broughton, or Adelphi nursery, Edinburgh, 7618.

Broughtonia, gynan. monan. and orchideae, a S. peren. genus an air-plant, requiring the same treatment as brassavola.

Brousse, M. — de la, his works on gardening, page 1119. A. D. 1772.

Broussadia, see Broussonetia, dicy. tetran. and utricella, a H. tr. Japan, which grows in common garden-soil, and is readily increased by layers.

Brown, Launcelot, Esq., a celebrated landscape-gardener, born at Cambol, or Campill, a few houses near the village of Hartburn, in Northumberland. He died in 1782, without issue, holding at the time the situation of head-gardener at Hampton-court, and possessed of considerable wealth, which he left to a nephew, 342.

Browne, Robert, a British writer on gardening, page 1109. A. D. 1786.

Browne, Sir Thomas, M. D., a British author on gardening, page 1110. A. D. 1658.

Browne, monad. decan. and leguminosea, a S. tr. W. Ind. which grows best in loamy soil, and cuttings of ripened wood will root in sand under a hand-glass in moist heat.

Brownsholme, a seat in Laneckshire, 7588.

Brooch, Bury, a seat in Hertfordshire, 7544.

Broxmore, a seat in Wiltshire, 7596.

Broxted Lodge, Durham, 7584.

Bruce, dicy. utricellata, a S. tr. Abyssinia, which thrives in loamy soil, and cuttings root in sand under a hand-glass in heat. Bruchus psi, 3042.

Brugmansia, monan. and solanaceae, a S. tr. Peru, which thrives in rich loam, and strikes from cuttings in moist heat.

Brutus, A. D., his works on gardening, page 1128. A. D. 1804.

Brutus, — a British writer on gardening, page 1110. A. D. 1790.

Brunia, pentan. monan. and rhamnaceae, G. tr. C. B. S. with heath-like leaves, which grow in sandy peat with a moderate supply of water, and young cuttings in sand, under a bell-glass, will strike root freely.

Bryan ford, a seat in Down, 7683.

Bryand, Charles, a British author on gardening, page 1109. A. D. 1774.

Bryony, see Bryonia.

Bubon, pentag. dig. and umbellifereae, G. tr. and G. bien. Eur. and C. B. S. grow freely well in loam and sand; all of which (except the ripened cuttings taken off at a joint, and planted under a hand-glass in sand, will root readily; the H. bien. species is of easy culture.

Bubroma, bastard cedar, polydod. dodec. and malvacceae, a S. tr. Jamaica, which thrives well in loam and peat, and cuttings root freely in sand under a hand-glass.

Buch, ic, Buch's icones plantarum.

Buchner, didyn. angios. and scrophularineae, a H. peren. N. Amer. which grows best in pots in loam and peat, and is increased chiefly by seeds.

INDEX.
an, Eur.; the first best grown in pots, and the other of common culture, and both increased by seeds.

Calahash-tree, — see Crescentia.

Calla, Dracunculus, and orchideae, a G. peren. N. S. W. which may be grown in loam and peat, and increased by division at the root.

Calamagrostis, trin. dig. and gramineae, H. peren. and Amer. of common culture, and increased by seeds or dividing at the roots.

Calamus, hexan. monog. and palmeae, S. tr. E. Ind. palms, which thrive best in sandy loam, and a warm, moist atmosphere, and are propagated by seed.

Calanthe, octan. tetrag. and sempervirens, D. S. tr. As. a.d Afr. succulents which thrive well in sandy loam, but require bottom heat to make them flower. "The leaves placed on a pot of mould, or on the tan, will shoot out young plants from the notches of the margin." (Sweet.)

Calathian violet, gentiana panmechanone.

Calceolaria, slipper-wort, dian. monog. and scor-pheantheae, G. peren. and. An. and Falkland islands, of easy culture, and propagated by seeds.

Calcutta, gardening of, 500.

Calder, pentan. monog. and scor-pheantheae, a. n. New Spain, of common culture.

Caledon Hill, Montréal, 7618.

Calenoc, venen. polyg. and corymbiferae, S. tr. and a S. bien, W. Ind. which grow in rich soil, and cuttings strike readily either in sand or mould.

Caled. Delph., Chalmers Calendula Depicta, an antiquarian work.

Caledon Hill, a seat in Tyrone, 7678.

Calendula, marjor, synon. peltal, corymb. fieberae, G. tr. and a G. peren. Eur. and C. B. S. which thrive in loam and peat, and cuttings root freely in the same soil under a hand-glass; and H. peren. is the easiest cultive.

Calendula officinalis, the common pot-margined, 4122.

Cally, hercian. monog. and aroidae, a G. and H. peren. Eur. and C.B.S. the first an aquatic, and the other a marsh plant of easy culture. C. asthi- qua will also grow well on the green-house stage.

Callow, a seat in Shirlingdale, 7631.

Callicarpa, tetan. monog. and verbenaeeae, S. and G. peren. Ind. which grow best in loam and peat, and ripened cuttings strike root in sand under a hand-glass in heat.

Callicoma, dolec. dig. and cunoniaceae, a G. tr. N. W. which thrives in loam and peat, and cuttings of ripe wood root readily in sand under a hand-glass.

Calligonum, dolec. tetrag. and poygnemae, a H. tr. Caspian Sea, which may be grown in loam and peat, and propagated by layers.

Callia, trin. monog. and commelleae, a S. peren. W. Ind. a creper of easy culture.

Callitachys, decan. monog. and leguminoseae, G. tr. H. peren. which grow fast and flower freely in loam and peat, and cuttings planted in sand under a bell-glass.

Callitriche, water-starwort, monandr. digyn. and naidaceae, a H. an. Brit. which grows on the surface of shallow water, and sends down delicate fibres to the soil below.

Calluna, octan. monog. and ericaceae, a H. tr. Brit. (family Ericaceae) the so-called heath; it requires to be grown in peat soil, and may be increased by seeds, layers, or cuttings of the young shoots planted in sand under a hand-glass.

Callodium, monog. meloe. and pittosporae, a G. tr. C. B. S. which, as the name imports, is of great beauty. It grows in loam and peat, and cuttings of ripe wood root readily in sand under a hand-glass.

Callodium, mononec. polyg. and aroidae, S. tr. and peren. Ind. and Amer. most of which grow freely in water, or in rich soil in a moist heat; they are propagated by tubers of the root.

Calony, — his works on gardening, page 1119. A. D. 1779.
Cavalleria (Ital.), a manège, or place for practising horsemanship.
Cavan, county of, as to gardening, 7570.
Cave Castle, Yorkshire, 7582.
Caversham, a seat near Reading, 7561.
Caves and caverns, as garden-decorations, 1814.
Cayenne, the evening culture.
Cephaelis, N. — de, his works on gardening, page 1121. A. D. 1806.
Cenanthis, p. monog. and rhamnaceae, S. tr. and L. of Amer. and W. Ind. which grow in loam and peat, and cuttings root freely in sand under a hand-glass. The H. tr. grow in common soil, and are readily raised from seeds or layers.
Cerastium, — to, as to gardening, page 1121. A. D. 1806.
Cecropia, snake-wood, dioc. dian. and urticae, a S. tr. Jam. which prefers a loamy soil, and large cuttings planted in sand under a hand-glass will strike root.
Cedric of Goa, cupressa lusitania.
Cedar of Lebanon, as to Pinnus.
Cedermuth, Baron Carl Wilhelm, his works on gardening, page 1130. A. D. 1740.
Cefalea, pentan. monog. and meliacae, a S. tr. W. Ind. which grows well in loam and peat, and cuttings root under a hand-glass in sand.
Celanie, — to, as Chelidonium.
Celastrum, aegypt. monog. and rhamnaceae, G. and H. tr. C. B. S. and Amer. requiring similar treatment to ceanothus.
Celeery, 1897, — to, as Atripium.
Celeno, common cock's bone, monog. and amaranthaceae, a S. bien. and an E. Ind. and China; of common culture.
Celeno, rutilans, the common cock's comb, 6485.
Cels, M. Francois, C. M. H. S. an eminent nurseryman at Mont-Rouge, Paris, 194.
Celtis, nettle-tree, polyg. monog. and amacanthaceae, S. tr. and H. tr. Eur. and Amer. which require only common soil and culture, and are increased by cuttings, layers, or by cuttings.
Cenchreas, trian. monog. and gramineae, a S. tr. and H. an. India; grases of the easiest culture.
Centaura benefica, the blessed thistle, 6200.
Centaurus, the Century, 6200.
Centunculus, bastard pimpinel, tetran. monog. and primulaeae, a H. an. Brit. of common culture.
Cephalis, pentan. monog. and rubiaceae, S. tr. Jam. and Afric. which thrive in loam and peat, and cuttings root freely under a hand-glass in sand.
Cephalanthus, button-wound, tetran. monog. and rubiaceae, H. tr. N. Amer. which grows best in loam and peat, and is propagated by layers or by cuttings.
Cephaphora, syngen. polyg. aquol. and corymboseae, a F. peren. Chili, which grows in sand and peat, and young cuttings root readily under a hand-glass.
Cerasium, mouse-ear, chick-weed, decum pentag. and caryophylleae, H. peren. and an. Eur. of the easiest culture.
Ceratocephalus, monog. monan. and chenopoeaceae, H. an. Tarary, of common culture.
Cerastina, cario-trousa, polyg. dicog. and legumi-noseae, a G. tr. Levant, which thrives well in loam and peat, and ripened cuttings root in sand under a hand-glass.
Ceratophyllum, horn-wort, monog. polyan. and naiadeae, H. peren. Brit. aquatics, of easy culture, and increased by seeds.
Ceratocephalus, monog. and apoceeyee, S. tr. S. Amer. and India, which grow in loam and peat, ripened cuttings root readily in sand under a hand-glass in moist heat.
Cereia, Judas-tree, dicog. monog. and leguminoseae, H. tr. Eur. and America, which grow in common soil, and are raised from seeds or layers.
Cereus, common money-wort, penta. monog. and bora-geniae, a H. tr. and an. Eur. of common culture.
Ceratium, horn-wort, monog. and solanaceae, G. tr. F. and W. Ind. which grow well in loam and peat, and cuttings root in sand under a hand-glass.
Ceylon, gardening of, 501.
Chaddesdon, a seat in Derbyshire, 7574.
Cherophyllum, chervil, pentan. dig. and umbel- lifereae, H. peren. bien. and an. Eur. and N. Amer. of the easiest culture.
Chalfont House, Buckinghamshire, 7546.
Chamedore, dicog. hexam. and palmaceae, S. tr. Caracas, which grows well in loam, and a strong moist heat, and is propagated by seeds.
Chamerops, polyg. dicog. and palmaceae, S. tr. S. Eur. and N. Amer. Palmirs requiring the same treatment as Chamaedore.
Chambors, Sir William, as an author on gardening, page 1103. A. D. 1757.

Chartularies, deeds of tenure of the ancient religious houses.
Chasselas, — his works on gardening, page 1119. A. D. 1790.
Chaste-tree, — to, as Vitez.
Chastagnorye, le Sieur de, a French writer on gardening, page 1115. A. D. 1692.
Chatelherault, a palace of the Duke of Hamilton, in France, and the name of an ornamental building in Hamilton Park, in Glasgow, 598.
Chatsworth, a seat in Derbyshire, 7515.
Chawstock, gomnisa domengenis.
Cheddar-ronet, galium verum.
Chelidonium, longifolium, filices, and filiceae, G. and H. peren. As. and Amer. ferns which grow in loam and peat, and require to be kept in a moist shaded situation.
Chemiranthus, wall-flower, tetrad. silig. and crucifereae, G. and H. tr. and peren. Eur. and Ace. under-shrubs and evergreen herbs, of easy culture in light soil, and propagated by seeds or cuttings.
Chelidonium, celandine, polyan. monog. and papaveraceae, H. peren. Eur. of the easiest culture.
Cheken, the Cheken angios and bignoniaceae, H. peren. N. Amer. elegant plants which grow in loam and peat, and are propagated by cuttings or by division in pots or cuttings.
Chesley Farm, Berkshire, 7561.
Cheltenham, a garden at, 7564.
Cheninmcreux (hollow way), a suburban villa at Paris, 164.
Chenar-tree, platanus orientalis.
Chenoloe, pentan. monog. and chenopoeaceae, a G. tr. C. B. S. and W. Ind. which grows in light soil, and cuttings root freely under a hand-glass.
Chenopodium, goose-foot, pentan. dig. and chenopoeaceae, G. peren. and H. peren. and an. Eur. and N. Amer. of the easiest culture.
Chenopodium bonus-henicus, 3791.
Chenopodium urbicium and album, 4200.
Cheesecaken, trip. and caryophyleae, a H. peren. Scot. a rock-work plant which grows in loam and peat, and is increased by dividing at the root.
GENERAL INDEX.

Chernes, a genus of plant-louse, nearly allied to aphids, and generally contended with the aphid, 2545.

Cherrier, J.—B., his works on gardening, page 1121. A.D. 1808.

Cherry—see Prunus.

Cherry-house, 2674; its culture, 3117.

Cherry-pepper, — see Capsicum.

Chervil,—see Cheirorrhynchum.

Chesham gardens and residences of, 7590.

Chesneé Montesvent, Charles de la, a French author on gardening, page 1116. A.D. 1654.

Chesnel, Marquis de, his works on gardening, page 1152. A.D. 1820.

Chesnut,—see Castanea.

Chevending, a seat in Kent, 7538.

Chick-pea, cicer arietinum.

Chickweed—see Stellaria.

Chillingham Castle, Northumberland, 7586.

Chimpania, decap. monog. and ericée, H. tr. N. Amer. rather difficult to preserve; they grow best in a bed of peat, and seldom transplanted.

Chimpanias, or floating gardens of Mexico, 491.

Chilococca, snow-berry, pentan. monog. and rubiacées, a S. tr. Jam. which thrives well in loam and peat, and cuttings root freely in sand under a hand-glass.

Chimanthus, fringe-tree, diam. monog. and oleine, H. tr. N. Amer. uncommon. An excellent species which grow in good loamy soil, and are increased by seeds or grafting on the common ash.

Chippacase Castle, Northumberland, 7586.

Chippingham Park, 7586, 1531.

Chitonia, pentan. monog. and gentianae, G. tr. C. B. S. which grow in peat with a little loam, and young cuttings root under hand-glasses in the same soil.

Chiswick House, Middlesex, 7521.

Chloris, yellow Wort, octant. monog. and gentianae, a S. tr. of common culture.

Chloranthus, chulan, tetran. monog. and loran-thaceae a G. tr. China, which may be treated as chenolées.

Chlorella, pentan. monog. and asphodelée, a S. and G. perren. AFR. grow in loam and peat, and are increased by dividing at the root, or by seeds.

Chocolate-nut, — see Theobroma.

Chocolate-salt, Cheshire, 7590.

Chonel, Noel, a French author on gardening, page 1116. A.D. 17—

Chorizia, tetran. monog. and rubiacées, a S. tr. W. Ind. which grows in loam and peat, and cuttings root readily in sand under a hand-glass in heat.

Chondria, syngen. polyg. aqual. and cichoraceae, a H. peren. France, which grows best in peat soil, and is increased by seeds or dividing at the root.

Chorizena, decan. monog. and leguminoseae, G. tr. N. Hol. which grows in sandy loam and peat, and produces seed in abundance.

Chorospermum, tetrad. silig. and crucifereae, a H. an. of common culture.

Christ, I. L., his works on gardening, page 1127. A.D. 1809.

Christ's thorn, sziphus pallurus.

Christmas rose, — see Helleborus.

Chrysanthemum, syngen. polyg. frustran. and corymbifereae, a G. an. of common culture.

Chrysanthemum, syngen. polyg. super. and corymbiferæ, a G. tr. and H. an. and perren. which grow in common garden-soil, and are increased by cuttings and seed, or by cuttings or seeds.

Chrysanthemum leucanthemum, 4316.

Chrysanthemum indicum, — see Antheims.

Chrysalisalea, decan. monog. and rosacées, a S. and G. tr. W. Ind. and Georgia, which grow in sandy loam, and large cuttings taken off at a joint, with their leaves uninjured, and placed thinly in a bed of sand, under a hand-glass, will strike root.

Chrysosoma, golden-locky, syngen. polyg. aqual. and corymbiferæ, G. tr. C. B. S. and Eur. which thrive in loam and sand peat, and cuttings root readily under a hand-glass.

Chrysophyllyum, star-apple, pentan. monog. and sapindaceae, a S. tr. which thrives in sandy loam, and cuttings of ripened shoots root in sand under a hand-glass, with a strong moist heat.

Chrysolepis, golden saxifrage, decan. dig. and saxifragées, H. peren. and Eur. which grow in shady moist places, and may be treated as marsh plants.

Chrysanthemum tr. dig. and gramineae, a H. an. of common culture.

Chulan, — see Cholanthus.

Cicely, — see Scordaria.

Cicer, chick-pea, diadal. decan. and leguminoseae, a H. an. of the easiest culture.

Cicuta, cow-bane, pentag. dig. and umbelliferées, H. peren. Eur. and Amer. which grow best in marshy places, and are increased by seeds.

Cimicifuga, bugwort, polyan. pentag. and ranunculaceae, H. peren. Eur. and Amer. of common culture.

Cinchona, pentan. monog. and rubiacées, S. tr. which grow in loam and peat, but not very freely, and ripe cuttings in sand under a hand-glass, in moist heat will strike root.

Cineraria, syngen. polyg. super. and corymbiferæ, S. G. and H. tr. and peren. Eur. and C. B. S. plants of easy culture, and propagated by cuttings, division, or seeds.

Cion,—see Cyan.

Ciona, erecta, water's nightshade, diam. monog. and onagriæsem, H. peren. Brit. creepers, which prefer moist shady situations, and grow in any soil.

Cissampelos, dice, monad. and menispermaceæ, a G. tr. and monad. S. Amer. climbers which grow freely in loam and peat, and cuttings root under a hand-glass.

Citrus, tetr. monog. and vitacées, S. G. and H. tr. Amer. and Ind. of easy culture in peat and loam, or in garden-earth, and readily propagated by cuttings; the S. and G. sorts in a moist heat, and the others in the shade under a hand-glass.

Citrus, rock-rose, polyan. monog. and cistacées, G. F. and H. tr. Eur. and Amer. under-shrubs, which thrive in common garden-soil, or in loam and peat, and may be increased by layers, or young cuttings taken off at a joint, and planted under a hand-glass, and frequently produced.

Citharexylum, fiddle-wood, dilyon. angios. and verbenaceæ, S. tr. W. Ind. which grow freely in loam and peat, and cuttings root in sand under a hand-glass.

Citizens' villas, 7385; management of, 7430.

Citrus, orange-tree, polyan. polyan. and aurantaceæ, G. tr. India and China, — see 4879.

Citrus aurantia, the lime, 4839.

Citrus aurantium, the orange, 4834.

Citrus decumana, the shaddock, 5902.

Citrus medica, the lemon and citron, 4896, 4897.

Citrus tribe, their propagation and culture, 5905, to 5954.

Clackmannanshire, gardens of, 7633.

Cladium, tetr. monog. and malvaceae, a H. peren. Eng. a grass of the easiest culture.

Clairs voyez (Fr.), open railings or barriers, 335.

Clarrici, Paolo Bartolomeio, his work on gardening, page 1118. A.D. 1757.

Clandon Place, a seat in Surrey, 7598.

Clare, county of, as to gardening, 7669.

Clare Hall, a seat in the county of Dublin, 7553.

Clarendon Place, a seat in Surrey, 7595.

Clary,—see Salvia.

Clayberry Hall, Essex, 7542.

Claytonia, perren. monog. and portulacées, H. peren. and Amer. N. Amer. and Silesia, of the easiest culture.

Claytonia perfoliata, as a spinage plant, 4327.

Clear Water, a seat in Gloucestershire, 7595.

Cleart-nut, strychnos potatorum.

Claveros, galium aparine.

Clematis, virgin's bower, polyan. polyg. and ranunulacées, G. tr. and G. F. tr. climbers, which grow in light, rich soil, and young cuttings strike readily under a hand-glass in heat. The H. species grow in any soil, and are increased by layers, dividing at the root or seeds.

Clemento y Rubio, Don Simon de Roxas, his work on gardening, page 1131. A.D. 1807.

Clermont, V. de Lowther, 7594.

Clerodendrium, dilyon. angios. and verbenaceæ, S. and G. tr. Ind. and China, soil half loam, a quarter rotten dung, and a quarter peat; they require a large pot to be lower freely, and young cuttings root readily under a hand-glass.
Cleome, tetrad, silic. and caparicadae, S. tr. bien. and an. Ind. and Amer. which grow in rich, light soil, and are readily increased by cuttings or seeds.

Clethra, decan. monog. and ericeae, a G. tr. and H. tr. N. Amer. the first thrives well in peat, with a little loam, a soil propagated by cuttings of seeds; the hardy sorts grow in peat and sandy loam, and are generally increased by layers.

Clinopodium, Buckinghamshire, 7547.

Clifforia, disc. polyan. and rosaceae, G. tr. C. B. S. which thrive well in loam and peat, and young cuttings rooted in sand under a bell-glass.

Clifton Hall, Nottinghamshire, 7576.

Climate, as it affects gardening, 518.

Climate of Great Britain, study of, 1920.

Cloudberry, stachys, 584.

Clonbrook, Clove-tree, 438.

Club-rush, Cocteau, 382.

Clown's rush, Clusia, 361.

Clypeola, Calceolaria, 264.

Cobacea, Caryophyllus, 173.

Coccoloba, with twine, 639.

Cock's foot-grass, see Dactylis.

Cocoa-nut, see Cocos.

Cocoa-plum, see Chrysobalanus.

Cocoa-nut tree, monac. hexan. and palmacea, S. tr. E. and W. Ind. palms of the usual culture.

Cocos nucifera, the cocoa-nut, 609.

Codarium, Codon, 565.

Codonopsis, Comely hall, 1676.

Coleus, clown, decan., and solanum, a G. bien. C. B. S. of easy culture.

Coffee, coffee-tree, pentan. monog. and rubiaceae, a S. tr. and W. Ind. which thrives well in loam and peat, and ripened cuttings root easily in sand under a hand-glass in heat.

Columnea, colpoon-tree, herba, 4067.

Comely hall, 1676.

Common acacia, — see Robinia.
Common dragon, arum dracontium.
Conocladia, maiden-plum, tran. monog. and terebinth, syn. S. W. Tr., which grow in loam and peat, and ripened cuttings in sand under a bell-glass in moist heat will strike root.

Compactus, Andrea, his works on gardening, page 1101. A.D. 1676.

Compost, composed soil, or composed dung; a mixture of earths, or of earths and manures, or of manure alone, and hence the terms compost-soil, and compost-manure; to collect and form, 1797.

Compost-ground, a place for laying and preparing composts, 1884.

Comptonia, monoc. tr. and amaranthaceae, a S. tr. H. N. Amer, which thrives best in peat soil, and is increased by layers.

Coniferous trees, their culture and management, 7393.

Conium, hemlock, pentan. dig. and umbelliferae, a G. tr. and H. bien. and an. Eur. C. B. S. and Barbary, which grow in any soil, and are increased by seeds.

Connoisseurs of gardening, 7408; their garden arrangements, 7429.

Convilus, button-tree, pentan. monog. and com- pretaceae, S. tr. W. Ind, which thrive well in loam and peat, and cuttings root in sand under a bell-glass in heat.

Conservatory, a habitation for ornamental plants of moderate temperature, in which the greater part are planted in beds or borders of soil, and are increased by cuttings and suckers, 6174.

Consistinpolyne, gardens of, 308.

Consumption in plants, 900.

Contortion in plants, 898.

Contracting gardeners, or new-ground workers, 7389.

Contrafieria root, dorstenia contrafieria.

Convolvaria, lily of the valley, hexan. monog. and milium palmeae, H. tr. Brit. of easy culture.

Convolvulus, blind-weed, pentan. monog. and convolvulaceae, tr. peren. and an. Eur. and Amer. of all the species the culture, mostly twiners, which grow readily in any soil, and are increased by the roots or seeds, and some by cuttings in sand.

Convolvulus batatas, the Spanish or sweet potatoate, Batatas, H. tr. A.D. 1699.

Convolvulus repans, a spinach plant in China, 6037.

Convolvulus soldanella, 4313.

Corydalis, fiebaune, syngen. polyg. super. and corym- biferaceae, tr. peren. and an. Eur. As. Amer. of all the departments which grow freely in loam and peat, and are increased by cuttings or seeds.

Cook, Moses, a gardening author, page 1101. A.D. 1676.

Cookie, wampee-tree, deean. monog. and aurant- iaceae, a S. tr. China, which thrives well in sandy loam, and ripened cuttings not deprived of any of their leaves, root in sand under a hand-glass in moist heat.

Cordia, bayberry, Warwickshire, 7572.

Coome Lodge, a seat in Oxfordshire, 7533.

Copernal, a seat in Essex, 7541.

Copaeira, balsam of capewe, deean. monog. and le- guminosae, a S. tr. S. Amer, which prefers a sandy loam, and ripened cuttings root in sand under a hand-glass.

Copford Hall, Essex, 7542.

Copris, a seat in Yorkshire, 7582.

Copped Hall, Essex, 7542.

Copco-wood, or copse-wood (from cooper, to cut, and copse, an enclosure which is cut by periodically, 6853.

Coprid, paper Coprise.

Copris, polyan. polyg. and ranunculaceae, a H. peren. N. Amer, which grows best in pots and in peat soil, and is increased by dividing at the root.

Coral-tree, — see Erythrina.

Coralher, gynan. monan. and orchideae, a H. peren. Scot, which grows best in peat soil, and is increased by seeds.

Corby Castle, Cumberland, 7593.

Corchorus, polyan. monog. and tiliaceae, S. tr. and an. Ind. Amer, which thrive in rich loam, and root readily from young cuttings; and a H. tr. of easy culture, and which roots from cuttings as readily as the common willow.

Cordia, pentan. monog. and boraginaceae, S. tr. and a peren. E. and W. Ind which grow in loam and peat, and cuttings root freely in sand under a hand glass in heat.

Coreopsis, syngen. polyg. frustr. and corymfbiferaceae, S. peren. bien. and an. W. Ind and Amer, which grow freely in rich light earth, and cuttings root under a bell-glass; and F. and H. peren. of easy culture.

Coriander, — see Coriandrum.

Coriandrum, coriander, pentan. dig. and umbiliffere- ceae, H. tr. of easy culture, 1770.

Coriandrum sativum, the common coriander, 4229.

Coriaria, ducie, deean. and .......... a H. tr. S. Eur of easy culture, increased by layers or suckers.

Coris, pentan. monog. and primulaceae, a G. bien. S. Eur of common culture.

Corispermum, hyssop, monan. dig. and chenopodi- aeae, H. an. of common culture.

Cork boat garden, 7666.

Cork-tree, quercus suber.

Corn-Flag, — see Gladiolus.

Cornelian-cher, corcus mascula.

Cornecupiae, tran. monog. and gramineeae, a H. an. Levant, of easy culture.

Corns, Georges, a French author on gardening, page 1115. A.D. 1560.

Cornus, dog-wood, tetran. monog. and caprifolins, H. tr. and ant. Eur. and N. Amer, of easy culture, excepting the two perennial species, which grow best in pots, or in a bed of peat.

Cornutia, didyn. angios. and verbenaceae, a S. tr. W. Ind, which thrive in loam and peat, and cuttings root in sand under a hand-glass.

Cornwall, gardens and residences of, 7601.

Coronilla, diadel, decan. and leguminosae, G. tr. Eur which thrive well in loam and peat, and are increased by cuttings or seeds; and H. tr. and peren. of common culture.

Correanum, pressure, metal, or perforated, Amer. sic. and crucifereae, H. an. Brit of easy culture.

Corraea, octan. monog. and dionsaceae, G. tr. which thrive well in sandy loam and peat; and ripened cuttings grow freely in sand under a bell or hand-glass.

Cornfield House, Wiltshire, 7501.

Cor Thom, I. E. her works on gardening, page 1127. A.D. 1814.

Coruta, bear’s-ear, saniecle, pentan. monog. and primulaceae, H. peren. Austria, which grows best in pots in loam and peat, and is increased by seeds or dividing at the root.

Corydalis, pink, deean. and papaveraceae, H. peren. Eur. and Amer which thrive in light, rich soil, and are increased by dividing the roots, or by seeds.

Corylus, nut-tree, nonco. polyg. and amaranthaceae, H. tr. Eur. and N. Amer.

Corylus avellana, the common nut-tree, and gar- den-liberty, 4752.

Corypha, palm, hexan. monog. and palmeae, a S. tr. which grows in light soil and strong moist heat.

Cosmea, syngen. polyg. frustran. and corymfbiferaceae, a G. peren and an. Mexico, of common culture.

Costmary, — see Balsamita.

Costus, monog. and zingiberaceae, H. peren.

India and S. Amer. reedy or marsh plants, increased by dividing at the root.

Cotchell House, Cornwall, 7501.

Cotia, — his works on gardening, page 1127. A. D. 1817.

Cottage, different kinds of, 749.

Cottage garden and gardeners, 7693.

Cottage garden of laborers, 7294; of artificers, 7482.

Cottage gardens, their management, 7418.

Cottage orchard, 7792.

Cotton-grass, — see Eriophorum.

Cotton-rose, glauco plants, 7792.

Cotton-thistle, see Onopordum.

Cotton-tree, — see Gossypium.

Cotyledon, navel-wort, decan. pentan. and sem- pervivaceous, tr. and a peren. C. B. S. suc- cculents of easy culture; and H. peren. rockwork plants, propagated by seeds or dividing the root.

Couch-grass, triticum repens.

Counsellors, or garden-artists, 7400.

Country-Residences of England, 7512; of Wales, 7605; of Scotland, 7615; of Ireland, 7651.

Convent, or Cornwall Market, its gardening productions with their average prices, 7314.

Cow, Francis, his works on English gardening, page 1104. A. D. 1733.

Cow-bane, see Cirsium.

Cow-itch, see Stizolobium.

Cow-parsnip, see Heracleum.

Cow-wheat, see Melica.

Cow, John, a British author on gardening, page 1103. A. D. 1729.

Cowfield House, Wiltsire, 7596.

Cowley, Abraham, a British author on gardening, page 1100. A. D. 1692.

Cowslip, see Primula.

Cox, William, his work on fruit-trees, pages 1114. A. D. 1817.

Craggo, garden of Marshal Loudon at, 582.

Craggan, a seat in Westmeath, 7692.

Craggie Hall, a seat in Kincardineshire, 360.

Crailing House, Roxburghshire, 7621.

Crame, colewort, tetrad. silic. and cruciferae, G. tr. and peren. and an. Eur. and Amer. which thrive in rich, light soil, and are increased by seed or dividing the root.

Cra Mareo, the sealsake, 3898.

Cram, John Andrew, his works on gardening, page 1124. A. D. 1766.

Cranberry, see Oxycoccus.

Cranbury, Cranford, Cress, Crinum, Crome, Crotalaria, Crowberry, Crowfoot, page 7621.

Crawes, a seat in Hampshire, 1811.

Crawes, the manor of, 1127.

Crawes, a seat in Hampshire, 7666.

Cross, William, his work on gardening, page 1127. A. D. 1841.

Cross-rocket, see Vella.

Crewe Hall, Cheshire, 7590.

Crichton, formerly a distinguished seat near Edinburgh, 3825.

Crimin, hexan. monog. and amyrislidi, S. G. peren. Amer. and Ind. which grow in rich loam with dung, in large pots, and are increased by cuttings, or by seeds. Ind. and Eur. peren. which grow in rich, loamy soil, and which are not considered by seed or by seedings. Amer. peren. which is grown in a shaded border, and is increased slowly by seeds, or dividing at the root.

Crimthun, samphire, pentan. and umbelliferae, a G. bien. and H. peren. which grow in light, sandy soil, and are increased by seed or by seedlings at the roots.

Crimthun maritimum, the common samphaire, 4578.

Crocus, trian. monog. and irideae, H. peren. Asia and Eur. bulbs of the easiest culture, 6585.

Cromartyshire, in respect to gardening, 7643.

Crone, G. his work on gardening, page 1127. A. D. 1841.

Crome Court, Worcestershire, 7566.

Crossandia, didyany. and acantetheae, a S. tr. P. 49, which thrive in rich, light soil, and cuttings root in sand under a hand-glass. Crosswort, see Crucianella. Croatalaria, diad. decan. and leguminoseae, S. and tr. bien. and an. Eur. Ind. and Afr. which grow in loam and peat, and are increased by young cuttings in sand under a bell-glass; some of these thrive in seeds. Croton, monog. monad. and euphorbiaceae, S. tr. and Ind. Amer. and Eur. which grow in loam and peat, and cuttings with their leaves are not root in sand under a hand-glass.

Crowberry, see Eupenium.

Crowes, decan. monog. a G. tr. N. S. W. which grows in sandy loam and peat, in an airy situation, and not over-watered, and cuttings root freely in sand under a bell-glass. Crowfoot, see Ranunculus.

Croxdale Hall, Durham, 7584.

Crucianella, cross-wort, tetran. monog. and rubia-
Cyclopedia, pentan. monog. and campylosumae, G. peren. C. B. S. which thrive in loam and peat, and cuttings root readily under a bell-glass in sand. Cypripedium, the gold carp fish, 6856. 
Cyprinid, lady's slipper, gynan. dian. and or- chideae, H. peren. Eng. and N. Amer. which will thrive in peat soil and in the shade, and are the better of protection during winter; they are difficult to increase, but sometimes they perfect seeds. Cyrenaica, gardens of, 6. 
Cyrilla, pentag. monog. and ericeae, G. tr. Cari- lina, which grows in sandy loam, and young cut- tings root in sand under a bell-glass, but not freely. 
Cyrantus, hexan. monog. and amaryllideae, G. peren. C. B. S. bulbs which grow in sandy loam and peat, require plenty of water when in a growing state; are scarcely any when dormant. 
Cytropodium, gynan. moian. and orchideae, S. peren. Amer. requiring the same treatment as cymbicae, 
Cysticarpus, diadel. hexan. and papaveraeeae, a H. an. C. B. S. of common culture. 
Cytisus, diadel. decan. leguminoseae, G. F. and H. tr. — see Nell. and Amer. chiefly shrubs which prefer a light soil, and are propagated readily by seeds or layers. 
Cytisus alpinus, the tree or Scotch laburnum, 7113. Cytisus laburnum, the shrub laburnum, 7560. 
Caartoryska, Princess Isabella, her work on gar- dening, page 1131. A. D. 1808. 
Dahlia 6329 D. 
Dactylis, cocksfoot-grass, tr. dig. and gramineae, H. peren. Eur. of the easiest culture. 
Dennia, pentan. dig. and asclepiadeae, S. tr. E. Ind. which grows in loam and peat, and cuttings root in sand under a bell-glass. 
Daffodil, — see Narcissus. 
Dahlkovn, G. T., his works on gardening, page 1130. A. D. 1728. 
Daherons, a French author on gardening, page 1116. A. D. 1898. 
Dalsford, a seat in Worcestershire, 7566. 
Dais, decan. monog. and thymeleaeae, a G. tr. C. B. S. which thrive freely in loam and peat, and may be increased by cuttings of the roots placed in a warm situation. 
Daisy, — see Dahlia. 
Dabarqia, diadel. decan. and leguminoseae, S. tr. E. Ind. which do well in sandy loam, and ripened cuttings root under a bell-glass in sand. 
Dales, decan. and thymeleaeae, a N. Amer. and G. an. and H. peren. Ind. and Amer. of common culture. 
Dalechampia, monoeae, monad. and euphorbiaceae, a S. tr. E. Ind. an ind. which grows in sandy loam, and roots freely in sand under a hand-glass. 
Dahouise Castle, Midlothian, 7618. 
Dalibaria, decan. polyg. and rossaceae, a H. peren. N. Amer. a creeper which prefers peat soil, and a shaded situation. 
Dalketh Park, Midlothian, 7618. 
Dalsinger, Pruner, his works on gardening, page 1131. A. D. 1778. 
Dahamoy, a seat in Midlothian, 7618. 
Dalmar Basse N., his works on gardening, page 1130. A. D. 1809. 
Dahmeny Park, kitchen-garden at, 2455; hot-houses there, 2961. 
Dalystown, a seat in Galway, 7672. 
Damascena, the damson, and Damascenus plum, — see Prunus. 
Damasosum, hexan. polyg. and hydrocharidaceae, a S. peren. an aquatic. 
Dampiona, pentan. monog. and goodenoveae, a G. peren. N. S. W. which grows well in loam and peat, and young cuttings root freely under a hand-glass.

Dan y Park, a seat in Brecknockshire, 7613. 
Dancer's Court, a seat in Tipperary, 7667. 
Dandelion, — see Leontodon. 
Danson Castle, a seat in Kent, 7557. 
Dauphine, octan. dig. and thymeleaeae, a S. tr. which thrives in loam and peat, and roots by cuttings under a bell-glass; and H. tr. beautiful shrubs, which prefer peat soil, and are increased by seeds or grafting on the D. laurea, 6562. 
D'Argenteuil, Dezallier Ant Joseph, a French author on gardening, page 1117. A. D. 1713.
Diplazium, cryptog. filices and filicce, a S. peren. Jamaica, a fern which grows in loam and peat in the shade, and is increased by seeds or dividing at the root.

Dipsacus, teasel, tetran. monog. and dipssace, H. bien, Eurt. of common culture.

Dipteris, tourn. - bean, diadel, decam. and leguminosea, a S. tr. Guiana, which grows in light loam, and ripened cuttings root in sand under a handglass in moist heat.

Dirca, leather-wood, octan. dig. and thymeleae, a H. tr. Virginia, which grows best in peat earth, and is increased by layers: snails are particularly fond of this plant.

Disa, gyuan. monan. and orchidee, a G. peren. Madeira, a trailing plant of common culture.

Dasipus, gyuan. monan. and orchidee, a G. peren. C. B. S. which may be treated as disa.

Diss, orient. gard., Chambers’s Dissertation on Oriental Gard. Ditchley, a seat in Oxfordshire, 7538.

Dittany, origanum dictamnus. Dictyum, gyuan. monan. and orchidee, a G. peren. N. S. W. revering the same culture as disa.

Dock, — see Rumex.

Dodartia, didyn. angios. and scrophularineae, a H. peren. Levant, which thrives in rich light soil, and is increased by seeds or dividing at the root.

Dodder, — see Cuscuta.

Dodonea, the Cudrich cowslip, pentan. monog. and protoscirpea, a H. peren. Virginia, which thrives in light loam, and is increased by dividing at the root.

Dodonea, octan. monog. and terebinthaceae, S. and G. tr. Austral. Amer. and Africa, which thrive well in loam and peat, and are increased by cuttings under a bell-glass in sand.

Dodder, Robert, a British author on gardening, page 1106. A. D. 1764.

Dogmersfield Park, Hampshire, 7294.

Dogbane, — see Apoemenon.

Dog’s cabbage, thelygonum cyanocarbe.

Dogtail-grass, — see Cynosurus.

Dogtooth-violet, — see Erythronium.

Dogwood, — see Cornus.

Dolichos, diadel, decam. and leguminosea, S. and G. tr. bien. and an. which grow freely in light rich soil, and are increased by a handglass or by seeds, which many produce freely.

Dolichos soya, or soy plant, 6657.

Dolv.-Myllynlyn, a seat in Merionethshire, 7612.

Don, — see Don Juan.

Donau, neal, doduce, and walvaceae, a S. tr. Mauritius, which grows in sandy loam, and ripened cuttings root in a pot of sand in moist heat under a hand-glass.

Don, David, Esq., F.L.S., librarian to the Linnean Society, 7045.

Don, George, of Forfar, a celebrated Buddhist bo-
m, 6821.

Dougalz, count of, as to gardening, 7258.

Douglas Grove, Berks, 7691.

Dounning Grove, Leicester, 7573.

Doodia, cryptog. filices and filicce, a G. peren. N. S. W. a fern of the usual culture.

Dorrnach, a sent, and also a mountain near Vienna, 294.

Doronicum, leatard’s bay, syngen. polyg. super. and corymbefere, H. peren. Eur. of common culture.

Dorsetshire, gardens and residences of, 7598.

Dorsetiana, tetran. monog. and urticaee, Eur. and S. Amer. which grow freely in light rich soil, and increase at the roots or by seed.

Doryanthie, hexan. monog. and amaryllideae, a G. tr. N. S. W. which grows in loam and peat, and is increased by suckers.

Dorycium, diadel, decam. and leguminosea, G. tr. and peren. S. Eur. which thrive in loam and peat, and young cuttings planted under a bell-glass in sand, root freely, or they may be raised from seeds.

Douche-stocks, 4537.

Douglas-Richardson, his works on gardening, page 1121. A. D. 1808.

Down, county of, its gardens and residences, 7653.

Downing, his seat in Flinthshire, 7603.

Draja, whitlow-grass, tetrad. silice and cruci-
fereae, H. peren. bien. and an. Eur. of easy cul-
ture.

Dracena, dragon-tree, hexan. monog. and asphode-
leeae, S. tr. E. Ind. which thrive well in light loam, and large cuttings stuck in the bark-bed in the autumn, root freely.

Draecophnum, dragon’s head, didyn. gymnos. and labiatee, a G. tr. and H. peren. and an. Eur. and Amer. of common culture.

Droserum, linden, hexan. monog. and aroidice, a S. peren. India, which grow in light rich soil, and are increased by dividing at the roots.

Dragon, — see Draconium.

Dragon’s head, — see Draecophnum.

Dragon-tree, — see Dracena.

Draining, 1095.

Dreghorn Castle, near Edinburgh, 7638.

Dryegisg, his works on gardening, page 1127. A. D. 1805.

Drill (driliren, Dutc. to bore holes with a drill), a lengthwise excavation formed in gardening by the bow for the purpose of inserting seeds. Some-
times drills are formed across beds by a large wide-toothed rake, and the same rake serves, when the banks are sprung up, to stir the soil between the rows, 1783.

Drill-rake, 3135.

Drinia, hexan. monog. and asphodeleae, G. peren. C. B. S. which grow in sandy loam and de-
cayed leaves.

Dronninggald, a seat in Denmark, 61.

Drosera, — see Cuscuta.

Drosera, cinnabarin. pentan. and droseraceae, H. peren. Brit. which grow in watery bogs in peat earth, but which will thrive and flower well when kept in small pots in the green-house. 'The soil should be filled three parts full of peat earth, and some moss placed on it, the drosera then planted in the moss, and the pots placed in pans of water." (Sceeh.)

Drotringholm, a royal garden near Stockholm, 246.

Drummond Castle, in Perthshire, 7633.

Dry rot, — see Merulius destruens.

Dry-stove, its construction, 6178.

Dry-stove plants, 6683; woody sorts, 6664; climbing, 6605; succulent, 6686; bulbous, 6657; her-

baceous, 6588.

Dryander, Jonas, M. D., an eminent botanist and bibliographer, who compiled the Bibliotheca Bankiana, and the greater part of the Hortus Kewensis, 7599.

Dryandra, tetran. monog. and proteaceae, G. tr. N. Holland. which require the same treatment as cunisia.

Dryas, low, polyg. and roseaee, a H. peren. Brit. which thrives best in a border of peat, and may be increased by cuttings dividing at the roots or by seeds, which it produces freely.

Dryburgh Orchards, in Berwickshire, 2220.

Drypis, pentan. tetrag. and Caryophyllaceae, a H. bien. Italy. of common culture.

Du Halde, a missionary who wrote on China and its gardening, 479.

Du Ham, Du Hamel’s Treatise on Fruit Trees.

Dublin, county of, its gardens and residences, 7633.

Edible fungi, 4356.

Edible wild and other neglected plants, 4393; greens and pot-hers, 4383; roots, 4600; leguminosae, 4393; halis, 4314; teas, 4317; variously applicable, 4352.

Edifices, anomalous, - ice-house, 1753; bee-house, 1754; Polish hives, 1758; common hive, 1759; glass hive, 1740; hive of Paltou, 1742; Huish’s hive, 1745; Howison’s hive, 1744; management of bees, 1745; position of the avairy, 1738; choice of bees, 1748; materials and size of hives, 1747; how to cover the hives, 1750; swarming, 1752; taking the honey, 1755; by total deprivation, 1757; by subjection, 1758.

Edifices, decorative, characteristic class; rocks, 1857; ruins, 1859; antiquities, 1840; rarities and curiosities, 1841; monumental objects, 1842; sculptures, 1843; vegetable sculptures, 1844; inscriptions, 1845; eye-traps, 1846; — see Structures used in Gardening.

Edifices, decorative, conventional class; prospect-tower, 1871; kiosque, 1872; temples, 1876; porches and porticoes, 1897; alcoves, 1870; Italian arbor, 1812; French arbor, 1815; caves and caverns, 1817; grottoes, roofed-seats, boat-houses, moss-houses, flint-houses, bark-huts, 1816; elegant structures, 1819; exposed seats, 1820; swings, 1821; constructions for displaying water, 1822; cascades, 1823; jets and other hydraulic devices, 1825; drooping fountains, 1826; sundials, 1834; vases, 1835.

Edifices, decorative, useful class, 1760; cottages, Gothick, Grecian, Chinese, Bengal, English, Scotch, Italian, Polish, Russian, Swedish, Danish, 1770; primitive huts, 1781; bridges, 1782; fallen to post-plank, Swiss bridge, 1785; bent plank, 1786; of common carpentry, 1789; of masonry, 1799; of cast-iron, 1798; boat-bridge, 1799; sequestration, 1789; to the gate, 1794; maintenance of gate’s passage, 1800; gates as decorations, 1800; gate with falling bars, 1799; rails, 1803.

Edifices of gardening, their further improvement, 1847.

Edifices used in gardening, 1858; economical buildings, 1859; head gardener’s dwelling-house, 1700; gardener’s office, 1700; seed-room, 1702; fruit-room, 1705; journeyman’s lodge, 1707; sheds, 1709; entrance lodges and gates, 1712; buildings for raising water, 1713; wells and pumps, 1716; conduits, 1717; reservoirs, 1718; tanks, 1719.

Edinburgh botanic garden, 7618.

Education of gardeners, importance of, 7719; professional education, 7724; intellectual, 7744; moral, religious, and physical, 7761; economical, 7771.

Edward’s Square, London, mode in which it is laid out, 7722.

Edwardsia, decan. monog. and leguminoseae, F. tr. N. Zealand, which grow in common soil, and are generally raised by seeds, but cuttings will root in sand under a bell-glass.

Edwinstown, seat in Co. Kilkenny, 7614.

Edwin’s lodge, — see Phalaeon.

Eggleston House, Durham, 7854.

Egmonian, — see Solanum.

Egmont Park, Wiltshire, 7649.

Eglington Castle, a seat in Ayrshire, 7877.

Elefers, tenebs, monog. and boragineae, S. tr. E. and W. Ind. which grow in loam and peat, and cuttings root readily under a hand-glass.

Elephant, charcoal, monog. and gramineae, a G. peren. C. B. S. a grass of common culture.

Eisenstadt (Iron Town), a seat in Hungary, 7826.

Elizabeth, decan. monog. and malaccenses, F. tr. C. B. S. which grow in loam and peat, and cuttings without their leaves shortened, root readily in sand under a hand-glass.

Elmagnus, tumares, monog. and eleagnaceae, S. and G. tr. Amer. and Ind. which grow in loam and peat, and ripened cuttings root freely in a pot under a sand-house.

Elmcorpus, elaeagnus and guttiferae, a S. and G. tr. E. Ind. and N. Holland which may be treated like eleagnus.

Elmsdenium, olive-wood, pentan. monog. and rhannaceae, Afr. and tropical, which grow in loam and peat, and ripened cuttings root freely in sand under a hand-glass.

Elms, olive, and dicre, hexan. and palmeae, a S. tr. a palm of the usual culture.

Elote, monoc. hexan. and palmeae, a S. tr. E. Ind. a palm of easy culture.
INDEX.

Escorial, palace of, in Spain, 294.
Esher Place, formerly a seat, in Surrey, 341.
Esparrel trees, such as are suitable for, or are planted against, espalier rails, 2508.
Esquiline, or spukey sale, of timber or iron, for the culture of fruit-trees, used as a sub- stitute for walls, 1576.
Essex, gardens and residences of, 7539.
Eston, a seat in Hungary, belonging to Prince Esterhazy, 2006.
Ethulia, syngen. polyg. equal. and corymbiferace, S. an.
Eveland, see Hesperantha.
Evelyn, Charles, a British author on gardening, page 1192. A. D. 1699.
Evela, dioec., dodec. and terebintaceae, G. tr. C. B. S. which grow freely in loam and peat, and cuttings root freely under a bell-glass in sand.
Evelina, polyg. equal., and corymbiferace, S. tr. and H. peren. Amer. of easy culture.
Evello, spurge, dodec. trig. and euphorbiaceae, S. D. S. and G. tr. and peren. Eur. As. Afr. and Amer. mostly succulent, which prefer loam and liane. Rubinil. Sweet says, "the way I have suc- ceeded in the best in striking the cuttings, is to stick them in the tan amongst the pots in a good heat, and not cover them with any glass." [Bot. Cyclopedia.
Euscal, polyg. monog. and hydrocholine, S. an.
Evergreen, an aquatic which often produces seeds, 6728.
Eustace, the Rev. John Chetwode, a Roman Catho- lic clergyman, author of an eloquent classical tour in Italy, 2 vols. 1810. 1813. He died of a fever at Naples in 1815.
Eustis, pentan. monog. and gentianace, a H. an. page 1102. A. D. 1699.
Euston Hall, Suffolke, 7552.
Eustrophus, hexan. monog. and asphodelace, a G. peren. Nut. which grows in sandy loam and peat, and is increased by dividing the root, or by cuttings under a bell-glass.
Eutaxia, decan. monog. and leguminoseae, a G. tr. N. Holl., which thrives best in sandy loam and peat, and young cuttings root freely in sand under a bell-glass.
Euthecia, pentan. monog. and gentoozen, a G. peren. N. Holl., which grows in sandy loam and peat, with little water, and may be increased, though slowly, by dividing the root or by seeds.
Evelyn, John, his writings on gardening, page 1190. A. D. 1658.
Evening flower, — see Hesperantha.
Evergreen trees, suitable for floricultural purposes, 6541.
Everingham, a seat in Yorkshire, 7582.
Everlasting, — see Gnaphalium.
Everlasting pea, lathyrus latifolius.
Evolvulus, pentan. dig. and convolvulaceae, S. an. both Indo-Malayan and culture.
Ewoot, a seat in Surrey, 7528.
Ex. Gard., Cultivating’s Exotic Gardener.
Exbury House, Hampshire, 7594.
Excavation of ground, 1867.
Excessively large, _see euphorbiaceae_, a G. tr. Chili, which will grow readily in light rich soil, and cuttings root in sand under a glasses.
Exotic culinary vegetables little cultivated in Brit- ain, 6022.
Exotic culture, healing operations of, 2501.
Exotic cuttings, little known, but deserving cultiva- tion, 5974.
Exotic fruits, neglected as such, 4876.
Expedients in the management of gardens, 7446.
Exford Hall, Hlutdishire, 7579.
Eyebright, — see Euphrasia.
Eyretuas, in gardening, 1846.
Eywood, Hertfordshire, 7585.

F.

Fabricia, _see_ Polyg. monog. and myrteacea, G. tr. Austro- nal, which thrive well in loam and peat, and young cuttings root readily under a bell-glass in sand.
Fallco, Nicholas, F.R.S., a British author on gar- dening, page 1101. A. D. 1689.
Fagara, tetan. monog. and terebintaceae, S. tr. and a G. tr. W. Ind. and Japan, which grow in light loam, and cuttings root in sand under a bell-glass.
Fagons, decan. monog. and rutaceae, a G. bien. and an. Candia and America, of common culture.
Fagus, monoece, polyg. and amertonece, _see_ Amer. and of easy culture, and increased by seeds; and some curious varieties by grafting or budding on the others.
Falx, a seat in the beechn-plant, 7088.
Fairechild, Mr. Thomas, his works on gardening, page 1102. A. D. 1725.
Fairy Hill, a seat in Hampshire, 7504.
Falicor, William, M.D., his works relative to gar- dening, page 1102. A. D. 1763.
Falkia, hexan. dig. and convolvulaceae, G. peren. C. B. S. a. creper of common culture and propa- gation, in loam and peat soil.
Falkland Palace, in Fife shire, 597.
Falta, Francesco, his works on gardening, page 1102. A. D. 1670.
Faron, his works on gardening, page 1191. A. D. 1804.
Farm, the situation for the home-farm of a reside- nce, 7571.
Farmer’s gardens of Middlesex, 7519.
Farmer’s gardens, their formation, 7263.
Farn Hill, a seat in Tyrewe, 7675.
Farneham, a seat in Cran, 7579.
Farrington, a seat in Devon, 7260.
Faschie, tetrad. silic. and crucifereae, a G. tr. Eur. which grows in loam and peat, and young cut- tings which grow in the same soil, under a bell-glass; and H. peren. and an. rock-work plants, which are increased by dividing the roots or by seeds.
Fatee gardens at Canton, 477.
Fawley Court, Buckinghamshire, 7547.
Fea-berries, a local name for gooseberries, — see Ribes.
Feabes, a local name for gooseberries, — see Ribes.
Feather-grass, spina pennata.
Fedra, trian. monog. and dipaceae, a H. tr. and an. Eur. of easy culture.
Feltig, a seat in Norfolk, 7554.
Felcho Tarkan, a seat in Hungary, 2006.
Felix Hall, Essex, 7542.
Fellenberg, M., a celebrated Swiss agriculturist, 1034.
Felling trees, 6635 to 6630.
Felwort, *Sweria peregrina*.

Fencewood, best trees for, 6739.

Fences, barriers for enclosure and defence; they are either *live fences*, formed by connected lines of woody plants, or *dead fences*, formed of earth, stone, iron, timber, or other mineral or dead vegetable matter.

Fences for plantations, 6529.

Fences in landscape-gardening, 6574.

Fennel, *6097*.—see *Anethum*.

Fennel-flower, —see *Nigella*.

Fenugreek, —see *Trigonella*.

Fernmanagh, gardens of, 7877.

Ferne orme, 7280.

Fernie, the seat of Voltair, near Geneva, 290.

Fernhill, a seat in Hampshire, 7594.

Ferns, exotic, their culture, 6733.

Feronia, elephant-apple, *polyg. mimosæ* and *....*, a *S. tr. E. Ind. which grow in loam and peat, and cuttings root in sand under a hand-glass.

*Ferrari, John Baptist*, his works on gardening, page 1128. A. D. 1653.

Ferraria, monadel. trian. and irideæ, *G. peren.*

C. B. S. bulbs which may be treated as *Ixiæ*.

Ferula, giant fennel, *pontian. dig.* and *ulmifolium*, *F. hirta*, a hardy perennial, which grow in common garden soil, and are increased by seeds.

Fescue-grass,—see *Festuca*.

Festuca, fescue-grass, *trian. dig.* and *giramnæ*, H. tr. and *an* of the easiest culture.

Fever-wort,—see *Pyrethrum*.

Fever-wort,—see *Triostemum*.

Fiearïa, pielewort, *polyan. dig.* and *ranunculaceæ*, a *H. peren. Brit. of common culture*.

Ficus carica, the fig-tree, 4889; culture of the fig-tree, *3145*; in the stove, *3101*; in the open air, *4851*.

*Field, Mr. Henry*, his history of the Chelsea garden, page 1114. A. D. 1820.

Fifehouse, gardens of, 7535.

Fif-house, gardens of, see *Ipswich*.

Fif-marigold,—see *Mesembryanthemum*.

Fig-tree,—see *Ficus*.

Figgot,—see *Scrophularia*.

*Filisier, N.*, his works on gardening, page 1119. A. D. 1783.

Filsmy leaf, hyoscyamum tumidigenæ.

Finsburh Hall, Suffolk, 7592.

Finger-grass,—see *Digitaria*.

Finningley Park cottage, Yorkshire, 7582.

Fit-tree,—see *Pinus*.

Fitchyt poured, *y. y.* his work on truffle hunting, page 1127. A. D. 1783.

Fisherton, formerly a seat in Warwickshire, laid out by Brown, and described by *Wheatley*. 

Fistness, a beauty in gardening, 7168.

Fitzwalters, a seat in Essex, 7541.

Flacouria, *dicr. icos.* and *tiliacæ*, *S. tr. E. Ind. which grow in loam and peat, and cuttings root in sand under a hand-glass.

Flagdiaria, hexan. *trig* and *junceræ*, a *S. tr. India*, which may be treed as *Cicuricatia.*

Flambilans, *Middlesex, 7530*.

Flat-pea,—see *Platylobium*.

Flax,—see *Linum*.

Flax—linum, *phormium tenax*.

Flea-bane,—see *Euphorbia*.

Flee, pellae pulicaria.

Flaxinga, diuded, *eran.* and *leguminosæ*, *S. tr. peren.* and *bienn.* India, which grow freely in loam and peat, and cuttings root under a hand-glass in sand plunged in heat.

*Florens, a seat in Roxburghshire, 7631*.

Flintshire, gardens and residences of, 7006.

Flixton Hall, *Suffolk, 7552*.

Flaxweed, *syzygium sophia*.

Florence Court, a seat in *Cavan, 7676*.

Floreiculture, 6075.

Floreicultural catalogue, 6290.

Florimania, 145.

Florists, on *country gardeners*, 7397.

Florists' flowers, enumeration of, 6021.

Florists' gardens, commercial, their formation, 7531; management, 7467.

Florists' societies, 7706.

Flower Hall, a seat in *Galway, 7672*.

Flower-fence,—see *Pocinaria*.

Flower-garden, formation of, 6076; exposure and aspect, 6080; extent, shelter, soil, surface, water, *an* of *manorial fence*, &c. 6081 to 6089; laying out the area, 6093; placing thehot-houses, 6093; flower-nursery, 6104; walks, edgings, *basket-edgings*, &c. 6153 to 6168.

Flower-gardens, its culture and management, 6187; times of planting or sowing, 6189; pruning and training, &c. 6191; *grass-plots*, 6191; protecting tender plants, 6192; water, 6193; insects and vermin, 1124; cutting off decaying flowers and herbage, 6193; gathering flowers, 6196; ordering seeds and bulbs, &c. 6200; neatness, 6201.

Flower-garden, planting of, 6110; mingled garden, 6111; select garden, 6119; botanic flower-garden, 6125; decorations, 6127.

Flower-pot, 6147.

Flower-stage, for pots of plants, 1528.

Flowering ash,—see *Ornus*.

Flowering fern,—see *Osmunda*.

Flowering rush, *butomus umbellatus*.

Flowers for borders,—see *Border-flowers*.

Flux of juices, a disease of plants, 885.

Fogs, 1354.

Fontainbleau, blue or clear fountain, a royal residence near Paris, the gardens of which are noted for the precocity and excellence of their grapes, 152.

Fontaines, Louis de, his works on gardening, page 1119. A. D. 1788.

Fontanacea, dian. monog. and *onagraceæ*, a *H. tr. Syria*, a hardy annual tender of frost, but which grows in common soil, and is increased by layers, or cuttings planted under a hand-glass.

Fonthill Abbey, *Wiltshire, 7597*.

*Forsythia* of *C. A. de*, 7493.

Footscray Place, Kent, 7583.

For, a treatise on *fruit-trees*, by *W. Forsyth*, Esq. royal gardener,—see page 1110. A. D. 1794.

Fordhok, a seat in *Middlesex, 7529*.

Foreign exotic culinary vegetables little cultivated in Britain, 6023.

Foreign fruits desiring introduction and cultivation, 5974.

Foreign fruits of *Africa*, 6318.

Foreign fruits of Asia, 6021.

Foreign fruits of *South America*, 6020.

Foreign fruits of the *West Indies*, 6019.

Foreign hardy culinary vegetables little cultivated in Britain, 4852.

Fornare, a seat in *Derbyshire, 7574*.

Foromen of gardens, 7581.

Forsket's garden, 7577.

Forsfarshide, gardens of, 7657.

Forficula auricularia, the earwig, a coleoptera insect, 1027.

Forking, 1030.

Foronica, the ant, a hymenoptera insect, which may be collected by whelming empty pots with the holes of their bottoms closed, near their haunts. The pots should be moistened with honied water or milk, 2282.

Forskoles, octan. tetrag. and *urticeæ*, a *G. peren.* and *H. tr.* in *C. S. of common culture*.

Forstal, A. W., Esq. his works on gardening, page 1119. A. D. 1791.

Forty Hall, a seat in *Middlesex, 7550*.

Fosbergilla, *polian. dig.* and *uvalnaceæ*, *H. peren.*

N. Amer. which require a peat soil, and are increased by layers.

Foulkbourne Hall, Essex, 7542.

Fountains and other hydraulic devices, 1482.

Foxglove,—see *Digitalis*.

Foxley, a seat in *Herefordshire, 7568*.

Foxtail-grass,—see *Alopecurus*
Fragaria, strawberry, ros., polyg. and rosacea, H. peren. Eur. and Amer. of the easiest culture.
Fragaria, the strawberry, to force, 3538; soil, choice of sorts, potting and preparation of the plants, time of beginning to force, temperature, air and water, treatment after gathering the fruit, 3534 to 3548.
Fragaria vesca and other species of garden-strawberries, their culture, &c., 4718.

Gardening, history of, 1.
Gardening, history of, from the 6th century B. C. to the 6th century of our era, 35.
Gardening, how arranged in this treatise, page 2.
G

GENERAL INDEX.

1191
Gardening, its products, pleasures, and cares, page 2.
Gardening, origin and progress of, 3.
Gardening authors, 7405.
Gardening in Britain, 312.
Gardening in China, 468.
Gardening in Europe, 630.
Gardening in Germany, 201.
Gardening in Holland and Flanders, 114.
Gardening in Ireland, 272.
Gardening in Mexico, 487.
Gardening in North America, 481.
Gardening in Sweden and Norway, 244.
Gardening in Switzerland, 240.
Gardening in Syria, Persia, India, and Africa, 457.
Gardening in the ages of antiquity as to fruits, culinary productions, and flowers, 25.
Gardening in the British colonies, and other foreign settlements of European nations, 403.
Gardening in Flanders, 456.
Gardening of the Jews, 5; of the Babylonians and Assyrians, 14; of the Persians, 19; of the Greeks, 53.
Gardening of the Romans, 56.
Gardening patrons, 7406.
Gardens, commercial, 7453; seed-gardens, grass-orchards, ploughed orchards, market-gardens, orchard-gardens, herbaceous physic gardens, market-flower-gardens, florists’ gardens, nursery-gardens, public gardens, squares, parks, botanical gardens, 1974 to 7459.
Gardens, different kinds of, in Britain, relatively to the different classes of society, and the different species of gardeners, 7412; private gardens, 7413; cottage gardens, nurseries, gardeners’ gardens, 7452; of farmers, 7453; of street-houses, 7454; of tradesmen, 7471; of amateurs, 7458; of connoisseurs, of citizens, of villas, of villas and demesnes, of monasteries, of royal palaces, 7453 to 7452.
Gardens, royal, — see Royal Gardens.
Gardens, the most celebrated in different countries, — see Gardening of those countries.
Gardens of England, 1715; Wales, 7392; Scotland, 7615; Ireland, 7651.
Gardens of the Horticultural Societies, 7508.
Gardens of the Nexted House, countries, 6.
Gardini, M., his works on gardening, page 1128. A. D. 1783.
Garnier, Claude, a French author on gardening, page 1143. A. D. 1631.
Garrett, a seat in Herefordshire, 7508.
Gartenbaumeister, 276.
Garton, James, a British author on gardening, page 1107. A. D. 1769.
Garuga, decan. monoc. and a, — see a, a S. tr. E. Ind. which may be treated like galega.
Gastrolobium, decan. monog. and leguminosae, a G. tr. H. north. which grows in loamy and peaty, and thrives best in sand or mould, under a hand-glass.
Gatecombe House, Hampshire, 7304.
Gatecombe Park, Worcestershire, 7366.
Gates, different kinds of, 1794; maintenance in position and repair, 1795.
Gates and lodges, 1792.
Gathering vegetables, operation of, 2383 to 2290.
Gatton Park, Surrey, 7228.
Gaulton Park, in Wiltshire, 7602.
Gautherin, decan. monog. and ericas, H. tr. N. Amer. creepers which thrive best in peaty soil, and thrive freely in sand or see.
Gautheria serpyllifolia, the common snowberry, 4774.
Gauria, octon. monog. and onagraceae, a S. tr. F. tropical in Brazil, 639.
Gautiero, Giuseppe, his works on gardening, page 1125. A. D. 1815.
Gazania, syngon. polyg. frutian. and corembiferae, a G. tr. C. B. S. which thrives in light, rich soil, and cuttings root freely in the same soil under a hand-glass.
Geiger, Fr. X., his works on gardening, page 1125. A. D. 1779.
Geissbühzla, tile-root, trian. monog. and iridaceae, H. peren. C. B. S. which may be treated like ixie.
Geisb, J., — see D. M., his works on gardening, page 1127. A. D. 1784.
Gelonium, dioec. lonic. and, — see A. tr. E. Ind. which may be treated like gardinia.
Gelsemium, pentan. monog. and apocynaceae, a H. tr. S. Amer. of common culture.
Gems, to propagate by, — see Bulbs.
Genip-tree, — see Genipa.
Genipa, genip-tree, pentan. monog. and rubiaceae, S. tr. S. Amer. which may be treated like gardenia.
Genista, diadel. decan. and leguminosae, G. and H. tr. of easy culture, and increased chiefly by seeds.
Gerassus, Ch. Jac., his works on gardening, page 1125. A. D. 1786.
Gentian, — see Gentiana.
Gentiana, gentian, pentan. dig. and gentianaceae, H. peren. Etr. and Amer. and annuals, which grow best in peat and loam, and the smaller sorts in pots; they are increased by cuttings, or dividing at the root.
Geudel, — see his works on gardening, page 1101. A. D. 1706.
Geodorum, gynan. monan. and orchidaceae, S. peren. E. Ind. which grow best in sandy loam and peat, and the shade of increasing them is by division at the root.
Geoffroya, bastard cabbage-tree, diadel. decan. and leguminosae, a S. tr. Jamaica, which grows in sandy loam, and cuttings root in the same soil under a hand-glass.
George, Dr., his works on gardening, page 1131. A. D. 1714 Gynan. Gerarde’s herball.
Geranie, table of species and varieties, 6001; propagation, 6002; culture, 6003; forcing, 6004.
Geranium, Dame’s violet, monog. decan. and geraniaceae, G. and H. peren. and an. Eur. C. B. S. and Amer. of easy culture, — see Geranum.
Gerardo, John, a British writer on gardening, page 1126. A. D. 1709.
Gerardia, didyl. angios. and scrophularineae, a S. peren. and H. peren. and an. E. Ind. and N. Amer. of easy culture.
German authors on gardening, 7583.
Germander, — see Teucrium.
Geropogon, old man’s beard, syngon. polyg. equal. and ciceroniae, a H. peren. and an. Italy, of common culture.
Gerthling, Joseph, his writings on gardening, page 1125. A. D. 1725.
Gertruce, — see his works on gardening, page 1123. A. D. 1715.
Gesneria, didyl. angios. and bignoniaceae, S. tr. Amer. which thrive well in light rich soil, and cuttings root either in sand or mould, under a hand-glass in heat.
Gethyllis, heban. monog. and antheraceae, G. peren. C. B. S. bulbs which may be treated like iris.
Getonia, angios. and compositae, a S. tr. E. Ind. which grows best in loam and peat, and cuttings root in sand under a hand-glass in heat.
Geum avens, lonic. polyg. and rosaceae, H. peren. N. Amer. and Eur. of the easiest culture.
Givent, William, a herbaceous botanic garden, 128.
Ghunia, dian. monog. and verbeneae, a S. an. W. Ind. of common culture.
Giant fern, — see Ferula.
Gibside, — see Dr. Whitaker, 7835.
Gibson, John, M. D., his writings on gardening, page 1107. A. D. 1768.
Gibson, T., his works on gardening, page 1107. A. D. 1691.
Giles, John, a British writer on gardening, page 1107. A. D. 1706.
Gillingham, William, a writer on gardening, page 1125. A. D. 1758.
Gillpay, the Rev. William, his works relative to gardening, page 1107. A. D. 1785.
Ginseng, panax quinquefolium.
Girod, — see M. M. de Ferriere d’Ermewnille, his works on gardening, page 1119. A. D. 1777.
Girdling trees, 883.
Gischia, pentan. pentag. and portulacaceae, a S. an. W. Ind. of common culture.
Glades in planting, regular or irregular, 6813.
Gladiolus, corn-dag, trian. monog. and irideae, G. and H. peren. C. B. S. bulsy of easy culture, 6518.
Glaucium, cuttings root in sand under a bell-glass in a moist heat.
Glaucium, pentan. dig. and asclepiaden, G. tr. C. B. S. which grow freely in loam and peat, and cuttings in sand under a bell-glass in a little bottom-heat, root freely.
Glaucium, cuttings root readily under a bell-glass; the other species are of easy culture.
Glochidion, tetran. monog. and onagraceae, a G. an. China, of common culture.
Globularia, dodec. and leguminoseae, a S. tr. peren. bien. and an. Ind. and Amer. of easy culture.
Glochidion, a G. of China, of common culture.
Goldschmidt, tr. dig. and leguminoseae, a G. tr. which grow freely in loam and peat, and cuttings root readily under a bell-glass.
Goddynia, diadel. decan. and leguminoseae, a G. tr. which thrive well in sandy loam and peat, and young cuttings root freely under a bell-glass.
Goddynia, a G. of China, of easy culture.
Golden tea, roots.
Gonophorites, dig. and leguminoseae, a F. and H. tr. Amer. and China, of easy culture, and increased by layers or seeds.
Gorinka, gramineaj, a tr. in culture.
Gorses, roots.
Gormley, Inverness-shire, 7648.
Gormsby, dodec. and fideceda, a G. an. S. of easy culture.
Gosse, dioen. and leguminoseae, a S. peren. E. In. in sandy loamy sand, and increased by dividing at the roots.
Gossypium, Gossypium, G. and E. in. and S. Ind. and Ind. Amer. of easy culture, and increased by cutting and seeds.
Gossypium, Gossypium, G. and E. in. and S. Ind. and Ind. Amer. of easy culture, and increased by cutting and seeds.
Gossypium, Gossypium, G. and E. in. and S. Ind. and Ind. Amer. of easy culture, and increased by cutting and seeds.
Gossypium, Gossypium, G. and E. in. and S. Ind. and Ind. Amer. of easy culture, and increased by cutting and seeds.
Gossypium, Gossypium, G. and E. in. and S. Ind. and Ind. Amer. of easy culture, and increased by cutting and seeds.
Gosforth, East Lothian, commonly called Wemyss House, 7586.
Gosforth House, Northumberland, 7619.
Gosseylum, cotton, monad. polyan. and malvaceae, S. tr. bien. and an. Ind. and Amer. which thrive in rich light soil, and generally ripen of seeds; or cuttings root under a bell-glass in sand.
Gouverneur, polyg. monoe., and rhham, S. tr. W. and E. Ind. which grow freely in loam and peat, and young cuttings root in sand under a bell-glass in heat.
Goues de Cisieres, his work on gardening, page 1118. A. D. 1758.
Gould, Sir, Englishman, in the service of Prince Potemkin, considered in his day as the first gardener in Russia, 271.
Goulard, — see Cicututia.
Goutweed, — see Rhyphophyllum.
Grafier, Mr. John, his works on gardening, page 1109. A. D. 1789.
Grafting, of trees, 1533.
Grafting, origin of, 33.
Grainmalt, cryptog. filices and filiceae, a H. peren. Brit. of the usual culture.
Grange Hall, Durham, 1758.
Grange Park, Hampshire, 7594.
Grapen, syngen. polyn. super. and corymbiferae, St. and N. Ind. of common culture.
Grape, — see Vitis.
Grape-gatherer, 1533.
Grape-hills, St. Non's betony.
Grass of Parnassus, — see Parnassia.
Gratiola, hedge-hyssop, dan. monoe. and cruciferae, a S. bien. and H. an. Eur. Ind. and Amer. of common culture.
Gravel, 1567.
Gray, Mr. Christopher, his work on gardening, page 1104. A. D. 1713.
Great barnet, — see Potentilla.
Great Fulford, a seat in Devonshire, 1700.

Grunelov, a seat in Cumberland, 1700.

Guadalcanal, a seat in Gloucestershire, 1700.

Guinea, a seat in Hampshire, 1700.

Gungywold, a seat in Herefordshire, 1700.

Gurapha, a seat in Hertfordshire, 1700.

Gurland, a seat in Hertfordshire, 1700.

Guren, a seat in Hertfordshire, 1700.

Guillemur, a seat in Herefordshire, 1700.

Gurner, a seat in Herefordshire, 1700.

Gurney, a seat in Herefordshire, 1700.

Habernaria, gynan. monn. and orchid.; H. peren. and Eur. and Amer. requiring the same treatment as gymnadenia.

Hack, a north country term for a pick-axe, — see Pick-axe.

Hackfell, scenery of, in Yorkshire, 7582.

Hacket, sceneryface, in Yorkshire, 7582.

Hacket, a botanical garden, 7521.

Hackett, scenery of, in Hampshire, 7582.

Hadden, scenery of, in Derbyshire, 7582.

Haddow Hall, Derbyshire, 7582.

Haddow Hall, Lancashire, 7582.

Hibberta, polyam. trig. and magnolacea, G. tr. Austral, which grow in sandy loam and peat, and cuttings root readily in the same soil under a hand-glass.

Hibiscus, monad. polyam. and malacaeus, S. tr. and G. peren. India, C. B. S. which thrive in rich, light soil, and cuttings planted in peat, or root readily by cuttings in sand under a hand-glass.

Hibiscus esculentus, 6035.

Hercium, hawkweed, syngen. polyg. equal and cichoraceae, H. peren. and an. Eur. and Amer. of the earliest culture.

High Cler, a seat in Hampshire, 729.

High Meadow, Gloucestershire, 7565.

Highclere Court, Gloucestershire, 7565.

Hill, Daniel M. Christopher, work on vegetable physiology, page 1112. A. D. 1800.

Hill, J. A. D. his works on gardening, page 1156. A. D. 1795.

Hill, Sir John, M. D., his work on gardening, page 1104. A. D. 1755.

Hill, Hylt, or Hylte, Thomas, his work on gardening, page 1139. A. D. 1794.

Hill, Hall, Essex, 7542.

Hill Park, Kent, 7537.

Hilla, hexan. monog. and rubiceae, S. tr. W. Ind. which grow in sandy loam and peat, and cuttings root in sand under a hand-glass.

Hillington Park, Norfolk, 7554.

Hillyborough Castle, a seat in Down, 7583.

Hillenbrand, Ant., his work on gardening, page 1194. A. D. 1777.

Himber, gardens of, in Hanover, 204.

Hippia, syngen. polyg. nccess. and corymbiferae, S. an. and G. tr. C. B. S. and E. Ind. which grow freely in any light soil, and cuttings planted in a hand-glass will root readily.

Hippocratea, tr. monog. and acereae, A. S. tr. Amer. which grows well in loam and peat, and cuttings root under a hand-glass in sand.

Hippocrepis, horeshoe-vetch, diasel. decan. and legumineae, A. S. tr. Minoreca, which thrives in loam and peat, and cuttings root readily under a hand-glass; and a H. peren. and an. Europe, of common culture.

Hippomannia, manchecile, monog. monad. and euphorbeaeae, S. tr. W. Ind. a powerful poison which grows in sandy loam, and cuttings root in sand under a hand-glass.

Hippophae, sea buckthorn, dicr. tetrad. and elag-aeae, H. tr. Eur. and Amer. which grow in any common soil, and are increased by layers or cuttings of the roots.

Hirschfeld, or Hirschfeld, Ch. Carolus L., his works on gardening, page 1134. A. D. 1764.

Hirtella, pentan. monog. and rosacea, A. S. tr. W. Ind. which grows in loam and peat, and cuttings root under a hand-glass.

Hill, Thomas, his works on gardening, page 1105. A. D. 1755.

Hoe, different sorts of, 1310.

Hoeing, 1752.

Hofmannseggia, decan. monog. and logumineae, A. S. tr. Chill; which grows in loam and peat, and cuttings, not too ripe, will root under a hand-glass in sand.

Hofland, Mrs., her writings on gardening, page 1114. A. D. 1830.

Hofwyl, an agricultural establishment near Berne in Switzerland, 1024.

Hog-plum, — see Spondias.

Hog-weed, — see Borrhavia.

Holme, a seat in Yorkshire, 7582.

Holwood House, Kent, 7557.
Hot-houses, contrivances for procuring water, wind, and air, 1288.

Hot-houses, details of the construction of their roofs, 1602; fixed roofs, moveable roofs, roofs partaking of both characters, materials of fixed roofs, moveable roofs, up-gaps, and objections to metallic roofs, 1063, to 1625.

Hot-houses, their pits, stages, shelves, doors, paths, &c. 1681; materials of the path, pits for tan or earth, beds and borders, shelves, stages, 1062, to 1687.

Hot-houses, their steam boilers and tubes, 1505; steam-covers of cast-iron, of wrought-iron, of copper, steam-pipes, hot water pipes, 1656, to 1670.

Hot-houses, their trellises, 1671; back wall trellis, middle trellis, front or roof trellis, fixed rafter trellis, movable rafter trellis, secondary trellis, cross trellis, 1672 to 1679; Hot-house entrance, 1680.

Hot-houses, their walls and sheds, 1649; front wall, holes for vine-stems, back wall, back shed, 1641, to 1647.

Hot-houses of the Chinese, specimen of, 480.

Hot-houses used in floriculture, 6161.

Hot-houses used in floriculture, their culture and management, 6202.

Hot-houses used in horticulture, 2944.

Hot-houses used in horticulture, their culture and management, 2946.

Hottentot cherry, cassinaria macrocarpa.

Hottentot fig, petal, monog. and primulacea, a R. peren. an aquatic.

Houghton Hall, Norfolk, 7555.

Hound's-tongue, see Eupatorium.

House, or mansion, situations best adapted for, 7293; aspect, 7553.

House, with carriage entrance, as a residence, 2059; with carriage entrance, 2620; house and conservatory, 3051; house and flower-garden, 2622; house and French parterre, 2633; house and front garden, 1654.

Houseleek, see Sempervivum.

Houstonia, tetran. monog. and rubiaceae, H. peren. N. Amer. rock-work plants, which do well in peat soil and water.

Hovea, diadeld. decem. and leguminosae, G. tr. Austral. which thrive in loam and peat, and young cuttings may be struck under a bell-glass in sand.

Hovenia, see Arctostaphylos.

Japan maple, or rhomachea, a G. tr. Japan; which grow in loam and peat, and ripened cuttings root readily under a hand-glass in sand.

Howick, seated in Northumberland, 7582.

Howe, a seat in Yorkshire, 7585.

Hoya, pentan. dig. and aclepiadea, a S. tr. Asia; a climber of easy culture.

Hucker, C., his works on gardening, page 1125.

Hucks, C. the plant, page 1101. A. D. 1665.

Huish, Robert, author and translator of some plays and novels, and of a work on bees, in which he seems to be an enthusiastic admirer and cultivator, 1573.

Hull botanic garden, 7581.

Humable plant, minima paludis.

Humulus, syngon. polyg. aegial and eoryombifera, G. binn. N. S. W. of easy culture.

Humulus lupulus, hop. duc. pentan. and urticae, a H. peren. Brit., see 1941.

Hunsdon, see Hunsdon.

Hunts, as garden buildings, 1751.

Hyneloth, see Hyneloth.
I. Iberis, a shrub, or a cult, tetrad. silic. and cruciferae, G. and F. tr. Amer. which grow in common soil, and are readily propagated by cuttings; and H. peren. and an. of easy culture.

II. Iep haus, its construction, 1789; management, 1730.

III. Ie-plant, meembyrranthemum crystallinum.

Iecolec, common Aegopodium, and apoecoeum, a S. tr. E. Ind. which thrive well in loam and peat, and cuttings root freely in sand under a hand-glass. Lekworth Park, 1725.

Ieolmullk, in 1826. Hebridies, early improvements there, 352.

Ihedphuson, near Madrid, gardens of, 294.

Ilex, horned, tetract., and rhomb. G. and F. tr. Amer. and Amer. which thrive well in loam and peat, and ripened cuttings root freely under a hand-glass in sand; the commoner H. tr. are increased by layers, and the finer sorts by grafting and budding.

IIe aquilicum, the common holly, 713.

Ilicecium, root-grass, pentan. monog. and amaranthaceae, a H. peren. Eng. a root which grows best in pots in light soil, and seeds ripen abundantly.

Illium, cut-and-tree, polyan. polyg. and magnol., a F. tr. Florida, which grows best in light loam, and is increased by layers, or ripened cuttings in sand under a hand-glass.

Impations balsamina, the garden balsam, 6479.

Imperatae, cut-and-root, pentan. and umbelliferae, a H. peren. Scot. of easy culture.

Implements, origin of, 31.

Implements of gardening, 1294; tools, 1895; the pick, lever, shovel, dibber, dibber's dibber, planter's back, planters's trowel, planters's pick-axe, garden trowel, transplanter, draw-hoe, prong-hoe, thrust-hoe, rake, drill-raise, hoe-raise, turfing-raise, turf-raise, turf-raiser, turf-scraper, wire-broom, dock-weller, besom, wire-besom, implement cleaner, 1296 to 1323.

Implement used in gardening, their further improvement, 1847.

Improvement, forming a plan of, 7364.

Improvement, rural, — see Landscape-gardening.

Implement, — see Landscape-gardener.

Indian corn, — see Zea.

Indian cress, — see Tropeolum.

Indian cuscuta, medicula virginica.

Indian fig, cactus opuntia.

Indian millet, sorghum vulgare.

Indian shot, conia indica.

Indigo, — see Indigofera.

Indigofera, indigo, diadel. decan. and leguminosae, S. tr. bien. and an. Ind. and C. B. S. which grow in loam and peat, and cuttings root readily in young wood under a bell-glass in sand; the H. an. are of easy culture.

Inga, polyg. monoc. and leguminosae, S. tr. E. and W. Ind. which grow in loam and peat, and cuttings root in sand in bottom heat under a bell-glass.

Ingestree Hall, Essex, 7542.

Ingestree Hall, Staffordshire, hawthorn-knife, asparagus-knife, grafting-chisel, forest-chisel, pruning-bill, forest-axe, pruning-saw, avvernuco.
but Pteridium, Inverary, Isola, Isles, Iron-tree, Iresine, Ipomopsis, Ixia, Isopogon, Isolepis, Isnardia, Isatis, Irrigation, Ireland, and an. glass, and peat, and same rains, and leaves bulbs, and young cuttings root readily under a hand-glass. 

Ipomea, pentan. monog. and convolvulaceae, S. peron, bien, and an. Ind. Amer. Eur. twiners which grow in rich light soil, and young cuttings root freely in sand under a hand-glass; the H. peren. and an. are the easiest culture. 

Ipomopsis, pentan. monog. and polemoniaceae, a G. bien and H. an. Amer. of common culture. 

Ireland, gardens and residences of, 703. 

Iresine, duce, pentan. and amaranthaceae, a F. peren. Amer. which grows in loam and peat, and is increased by dividing at the root. 

Iris, trian. monog. and irideae, G. and H. peren. Europ. and Amer. which grow in loam and peat, and increased by dividing at the root; some of them may be treated as marsh plants. 

Iris persica, tuberosa, susiana, xiphium, &c. 6394. 

Iron-tree, sideroconium triflorum, Iron-wort, — see Sideritis. 

Irrigation, 1868. 

Istroba, lepid. silic. and crucifereae, a H. peren. bien and an. Eur. of easy culture. 

Iscchium, polyg. marc. and gramineae, a S. peren. and an. Ind. of common culture. 

Isolepis, S. Isles of Anglesea, and gardens and residences of, 703. 

Isolepis of Man, as to gardening, 7588. 

Isles of Jersey and Guernsey, as to gardening, 7389. 

Istardia, tetran. monog. and onagraceae, a H. an. of easy culture. 

Ischocilus, gynan. monan. and orchideae, S. peren. and W. Ind. parasites which may be treated as aérilles, epidermum, &c. 

Isocit, quillwort, cryptoc. hydrog. and marsileaceae, a H. peren. Brit. a marsh plant. 

Isola bella, gardens of, 52. 

Isolani, trion. monog. typhaceae, a H. peren. and an. Brit. grasses of common culture. 

Isopocon, tetran. monog. and protaceae, G. tr. N. Holm. which grow in peat and sand well drained, and ripened cuttings root under a hand-glass, care being had to take off the glass occasionally to avoid damping. 

Ispopyrum, polyg. and ranunculaceae, a H. peren. and an. Eur. of easy culture. 

Italian books on gardening, 7049. 

Itea, pentan. monog. and saxifragaceae, a H. tr. N. Amer. which thrives well in sandy loam, and is increased by layers. 

Iva, syngon. polyg. necess. and corymbifereae, a S. tr. Can. Amer. both of common culture. 

Ivy, — see Hedera. 

Ixca, trian. monog. and irideae, G. peren. C. B. S. bulbs which grow best in sandy loam and decayed leaves of peat, and sand well drained, which have done flowering: they will do well in beds in the open garden treated in the same manner as cannas, guarding against frost and heavy rains, — see 6319. 

Ixodia, syngon. polyg. equal. and corymbifereae, a G. tr. N. Holm. which thrives best in sandy loam and sandy peat, and cuttings root freely in the same kind of soil under a hand-glass. 

Ixora, tetran. monog. and rubiaceae, S. tr. E. Ind. and, as a shrub, of greenhouse culture, which thrive well in loam and peat, and cuttings root freely in sand under a hand-glass. 

J. 

J. or Jus, A. J. de Jacquin's Genera Plantarum. 

Jacc, auct. J. Jacquin Flori Austriaca. 

Jac. vind., N. J. Jacquin Hortus botanicus Viennobonensis. 

Jacaea, arctocarpus integrifolia. 

Jacaranda, a-box, hennanica sonora. 

Jacksonia, dian. monog. and onagraceae, G. tr. N. Holm. which grow in sandy loam and peat, and young cuttings may be rooted in sand under a hand-glass or ripened on pots under a hand-glass. 

Jacob, R., his works on gardening, page 1123. A.D. 1797. 

Jacobseil, a seat in Sweden, 498. 

Jacqy, of Restad, a German gardener, employed by the Grand Seigneur at Constantinople, 398. 

Jacquinia, pentan. monog. and sapotaceae, S. tr. W. Ind. which thrive freely in loam and peat, and cuttings (with care) will root in sand under a hand-glass. 

Jadap, ipomoea jalapa. 

Jacintha, mass-eiser. 

Japonicola, octan. monog. and onagraceae, a S. tr. which grows in light loam, and cuttings root freely in sand under a hand-glass. 

Japon, gardens of, 469. 

Jardin electoral de Saxe, at Warsaw, 281. 

Jardin des Plantes, at Paris, described, 7331. 

Jasione, sneeze's scabious, pentan. monog. and campanulaceae, a H. peren. and an. Eur. which do well in common soil, or in pots (being rather tender of frost), and are increased by cuttings or seeds. 

Jasmine, — see Jasminum. 

Jasminum, dian. monog. and jasminaceae, S. and G. tr. E. Ind. and Amer. S. tr. which grow in loam and peat, and cuttings root readily in sand under a hand-glass; the H. tr Eur. grow in common soil, and are increased by layers or cuttings. 

Jatropha, physic-nut, monan. and euphorbiaceae, S. tr. peren. and an. W. Ind. which thrive well in loam and cuttings root best stuck in the tain in a good heat. 

Jawne, St. Hilaire, his works on gardening, page 1121. A.D. 1830. 

Jenner, F., his works on gardening, page 1122. A.D. 1816. 

Jeffersonia, octan. monog. and papaveraceae, a H. peren. N. Amer. which grows best in peat, and is increased by seeds or dividing at the root. 

Jet d'eau, spout or fountain of water, 1829. 

Jock's lodge nursery, Midlothian, 7618. 

Johnson, Thomas, M.D., his work on gardening, page 1099. A.D. 1829. 

Jonesia, heptan. monog. and .........., a S. tr. 12 Ind. which grows freely in light loam, and large cuttings root well in sand under a hand-glass. 

Jordens, J. H., his works on gardening, page 1125. A.D. 1739. 

Journeymen gardeners, 7390. 

Juglans, walnut, mono. polyg. and terebintaceae, H. tr. N. Amer. increased by layers or seeds, and some kindly budding and inarching. 

Juglandis, B. F., his work on gardening, page 7453; as a fruit-tree, 7066. 

Julien, A., — see his work on gardening, page 1122. A.D. 1819. 

Julius, nux, hexan. monog. and juncaceae, H. peren. Brit. grasses, generally marsh plants. 

Juniperus, duce. monag. and conifereae, F. and H. tr. Eur. a more delicate species prefers peat and soil; but the cedar and savin grow in common garden earth: they are best managed by seeds, but cuttings may be rooted under a hand-glass. 

Justic, Bernard de, his works on gardening, page 1117. A.D. 1739. 

Justicia, dian. monog. and acanthaceae, S. and G. tr. and an. Ind. and Amer. chiefly aquatics of common culture. 

Justice, James, Esq. F. R. S., his works on gardening, page 1104. A.D. 1734. 

Justice, dian. monog. and acanthaceae, S. and G. tr. and an. Ind. and Amer. of easy culture in loam and peat, and cuttings root freely in heat under a hand-glass.
K.

Kämpferia, galangale, dian., monog. and scitaminee, S. peren. E. Ind. which grow freely in rich light soil, requiring little water when not in a growing state, and are increased by dividing at the root.

Kaufmann, a Keldoscope of Dr. Bradley, 6109.

Kailan, gardens of, in the East Indies, 462.

Kalon, Peter, his works on gardening, page 1130. A.D. 1754.

Kalan, tuh. ocean. mohod and rhobarcan, H. tr. N. Amer. under shrubs which require peat soil, or very sandy loam, and are increased by layers or seeds.

Kanguri, vine, eissus antarectum.

Kreet, J. G., his works on gardening, page 1277. A.D. 1813.

Mallows, — see Malva.

Malo, Charles, his work on gardening, page 1152. A.D. 1815.

Malope, monad. polyan. and malacaceae, a. G. bien. and barb. of easy culture.

Malpighia, Barbadoes cherry, decan. trig. and malpighiaceae, S. tr. W. Ind. and Amer. which grow in light soil, and ripened cuttings are not difficult to root under a hand-glass in sand.

Malva, gardening of, 506.

Malva, mallow, monad. polyg. and malacaceae, G. tr. Eur., Afr. and H. an. and bien. Eur. which succeed in any light, rich soil, and cuttings root freely under a bell-glass in sand, or under a hand-glass in any light soil; seeds are also frequently produced in the manure.

Mammee, mammee-tree, polyg. monan. and gut-
tiereae, a. tr. S. Amer. the mammee-tree, 5198.

Management of gardens, see Management.

Management of gardens, science of, 2334.

Manchinea, hippocampe manchilina.

Man德拉, — his works on gardening, page 1118. A.D. 1717.

Mandragora, mandrake, pentan. monog. and salicaceae, a. H. peren. Levant, which succeeds well in light, sandy soil, and is increased by seeds.

Mandrake, — see Mandragora.

Manetia, tetran. monog. and rubicinaceae, a. tr. S. Amer. Guiana, which grows in loam and peat, and cuttings root readily under a hand-glass.

Mangifer, mango-tree, pentan. monog. and tere-
bintaceae, a. tr. S. E. Ind. 5996.

Mango-tree, mangifer indica, 5996.

Mangosteen, Mangostana.

Manursis, polyg. monec. and gramineae, S. an. E. Ind. of common culture.

Mansion and offices, their situation, 7429.

Mansion-office, 7571; their management, 7443.

Manulea, didyn. angios. and scrophulariaceae, G. tr. bien. and an. C.B.S which grow in light rich soil, and are readily increased by young cuttings planted under a hand-glass.

Manures, 1111; of animal and vegetable origin, 1112; theory of their operations, from land plants, sea weeds, dry straw, inverte peaty matter, wood ashes, animal substances, bones, blood, urine, night-soil, dung of fowls, of cattle, preservation of manures of animal and vegetable origin, 1113. to 1116.

Manures of mineral origin, 1153; theory of their operation, different species, lime, chalk, marl, magnesia, gypsum, application of mineral ma-

Manure Hill, a seat in Middlesex, 7290.

Marble Hill Cottage, Middlesex, 7550.

Marcevania, polyg. monad. and capparaceae, a. tr. W. Ind. which grows in loam and peat, and roots by cuttings.

Marchand, — a French author on gardening, page 1116. A.D. 1701.

Marte’s tail, — see Hippuris.
GENERAL INDEX.

Myrica, cangleberry-myrtle, diosc. tetran. and ameetence, G. tr. C. B. S. which grow in loam and peat, and cuttings root freely under a bell-glass; the H. tr. Brit. and Amer. prefer a moist peat soil, and are annually increased by seeds or layers.

Myriophyllum, water-milfoil, monoe. polyandric and naledace, H. peren. Brit. aquatics increased by seeds.

Myristica, the nutmeg, diosc. monad, and myristicee, S. tr. Ind. which grow in light loam, and have yet been little propagated.

Myrothamnus, monad, polyan. and malvaceae, a S. tr. W. Ind. which grows readily in light, rich soil, and cuttings root readily in sand under a bell-glass.

Myrt, — see Myrth. Myrth, myrth, pentan. dig. and umbellifere, a H. peren. Brit. of easy culture.

Myrtus, myrtle, linn. monog. and myrtaceae, G. tr. C. B. S. evergreens which grow in loam and peat, and cuttings root readily in sand under a bell-glass.

Myrtophyllum, hexan. trig. and similaceae, G. peren. C. B. S. climbers which thrive in loam and peat, and are increased by division at the root.

Myrtus, myrtle, linn., monog. and myrtaceae, G. tr. Eur. and W. Ind. which grow freely in rich loam, and are increased by cuttings; M. tomentosa requires the heat of a dry stove, and the cuttings, which must not be too old, will root under bell-glasses.

N.

N. Cours, s. Nouveau Cours complet d’Agriculture, k. c. page 110. A.D. 1790.

Nails and other fastenings for wall-trees used in gardening, 1514.

Nairnshire, as to gardening, 7642.

Nama, pentan. dig. and convolvulaceae, a S. an. Jamaica, of common culture.

Nandina, hexan. monog. and berberideae, a G. tr. China, which thrives well in loam and peat, and ripened cuttings, with their leaves not shortened, will root in sand under a hand-glass.

Nannaw, a seat in Merionethshire, 7612.

Nana, monad, polyan. and malvaceae, H. peren. Virginia, which grow freely in common soil, and increase by seeds or dividing the roots.

Naravelia, polyan. polyg. and rhamnaceae, a S. tr. Ceylon, a climber which grows in loam and peat, and young cuttings planted thinly in a pot of sand, will root under a hand-glass.

Narcissus, hexan. monog. and amaryllidaceae, H. peren. Eur. bulbs of common culture: the daffodill narcissus, the white narcissus, the jonquil, and polyanthus narcissus, 6284.

Nardus, mat-grass, tris. monog. and garamniec, H. peren. Eur. grasses of easy culture.

Narthexium, hexan. monog. and asphodelaceae, H. peren. Brit. and Amer. of easy culture in peat, 6750.

Naseberry-tree, achras sapota, var. B. zapotiila.

Nasturtium, tetrad. siliqu. and cruciferaceae, H. peren. and an. Eur. two of which are aquatic, and the other a garden culture.

Nasturtium officinale, the common water-cress, 4652.

Native or neglected fruits which might be cultivated and improved, 4764.

Nauclea, pentan. monog. and rubiaceae, a S. tr. Ind. which grows well in loam and peat.

Nebeliea, syn. syngon. segr. and corimbifere, a H. an. S. Amer. of common culture.

Navelwort, — see Cotyledon.

Navestock Hall, Essex, 7645.

Necol’s seat in the county of Mayo, 7673.

Necol’s, Adam, his Orchid catalogue, 7588.

Neatness, its importance in gardening, 2551.

Nefiet, — see his work on gardening, page 1100.

A.D. 1791.

Nelt, Patrick, Esq. secretary to the Caledonian Horticultural Society, his writings on gardening, page 1114.

Nelumbium, sacred bean, polyan. polyg. and hydrocharideae, S. peren. India and Carolina, aquatics increased by seeds, and dividing at the root, 6750.

Nemesia, didyn. angios. and scrophulariaceae, G. peren. and an. C. B. S. which grow in any light rich soil; and young cuttings planted under a hand-glass, will soon strike root.

Neotia, gynan. monan. and orchideae, S. peren. W. Ind. which thrive best in loam and peat with little water, and the plants are increased by dividing at the root.

Nepenthes, pitcher-plant, a S. peren. China, an aquatics, as yet scarce in British gardens.

Nepeta, catmint, digyn. gymnos. and labiateae, H. peren. Eur. of the easiest culture.

Nephele, monan. pentan. and corimbifereae, a S. tr. E. Ind. which grows in loam and peat, and cuttings root in sand under a hand-glass.

Nephrodiun, kidney-fern, cryptog. filices et filices, S. and H. peren. ferns of common culture.

Nerium, oleander, digyn. dig. and apoecyceae, G. and S. tr. Eur. and Ind. which thrive in light, rich soil, and cuttings root readily in sand plunged under a hand-glass in moist heat.

Netting, for shelter, 1512.

Nettle-rose, — see Celta.

Nettleworth, a seat in Nottinghamshire, 7576.

Neuenhahn, K. Ch. Adf. his work on gardening, page 1125. A.D. 1796.

New Cross nursery, Deptford, 7536.

New-ground workmen, — see Contracting Gardeners.

New Jersey tea, — see Ceanothus.

New Tartar, a seat in Ross-shire, 7647.

New Zealand, leptosperm um scoparium.

Newbattle Abbey, Midlothian, 7618.

Newbrook House, a seat in the county of Mayo, 7673.

Newby Hall, Yorkshire, 7582.

Newlinton, a seat in Linliithgowshire, 7635.

Newpark House, a seat in the county of Mayo, 7673.

Newstead Abbey, Nottinghamshire, 7576.

Newton, a seat in Hampshire, 7504.

Newton, a seat in the county of Tipperary, 7657.

Newton Hall, Durham, 7584.

Newton House, a seat in Caernarvonthshire, 7514.

Newtown Mount Kennedy, a seat in Wicklow, 7645.

Newtown Park, a seat in the county of Dublin, 7653.

Nicandra, pentan. monog. and solanaeeae, a H. an. Peru, of common culture.

Niches, in arboreticume, 1813.

Nicker-tree, guillandina bondou.

Nicot, Walter, his works on gardening, page 1112. A.D. 1798.

Nicotiana, tobacco, pentan. monog. and solanaeaceae, a G. tr. peren. and H. an. America and China, which thrive in any light soil, and are readily increased by seeds.

Nigella sativa and arvensis, as culinary plants, 4035.

Nightschade, — see Solanum.

Nipplcowort, — see Lupana.

Nissolia, diadal. decan. and leguminoseae, a S. tr. S. Amer. which thrive in sandy loam, and cuttings may be rooted in sand under a hand-glass.

Nitraria, dodoc monog. and ficeolidae, a H. tr. Siberia, which thrives best in sandy loam, with some salt occasionally put round it, being a salt marsh plant; it may be increased by layers or cuttings under a hand-glass in sand.

Nivenia, tetran. monog. and proteaceae, tr. and peren. C. B. S. which grow in soft loam, peat, and sand, the pots well drained and placed in any situation; rooted cuttings taken off at a joint without shortening their leaves, will root in sand under a hand-glass, in a cool shady situation.

Nolans, pentan. monog. and boraginoseae, a H. an. Peru, of common culture.

Nolana, hexan. trig. and melannaceae, a H. peren. Georgia, which thrives best in peat soil, and is increased by seeds or dividing at the root.

Norwich Upland, 7588.

Norton Park, a seat in Berkshire, 7577.

North, S. Amer. which thrives in sandy loam, and cuttings may be rooted in sand under a hand-glass.
Northcourt House, Hampshire, 7394.
Northumberland, gardens and residences of, 7398.
Northwicke, Worcestershire, 7366.
Norwich, celebrated for its florists, 7532.
Nottinghamshire, gardens and residences of, 7756.
Novel, E. de Bot., Reichard's Nouveau Éléments de la Botanique, 7753.
Novar, a seat in Ross-shire, 7397.
Nunecham Courtenay, Oxfordshire, 7538.
Nummery, seat in Devonshire, 7548.
Nuphar, polyan. monog. and hydrocharidee, H. peren. Eur. and Amer. aquatics of easy culture, and increased by dividing at the root, or by shootings, 7342.
Nurseries, public, of Middlesex, 7518; of Surrey, 7293; of Kent, 7535.
Nurseries, public, its formation, 7335; management, 7498.
Nursey for trees, its formation, 6073; culture and management, 6082.
Nursery foreman, 7851.
Nursery gardeners or nurserymen, 7399.
Nut-bearling fruit-trees, 4732.
Nut-tree, — see Corylus.
Nutmeg, — see Myristica.
Nutwell, a seat in Devonshire, 7500.
Nyctanthes, dian. monog. and jasminenee, a S. tr. Per. which grow in soil and peat, and cuttings, not too ripe, root readily in sand under a hand-glass.
Nysa, tulopo, polyg. dioec. and sanctahæe, H. tr. Amer., which thrive in common soil, but prefer a damp situation; they are increased by layers or seeds.

O.

Oak, — see Quercus.
Oakley Grove, Gloucestershire, 7565.
Oakley Park, Shropshire, 7569.
Oaks, a seat in Surrey, 7298.
Oest, — see Avena.
Oatlands, Surrey, 7398.
Ochca, polyan. monog. and guttiferenee, a S. and G. tr. E. Ind. and C. B. S. which grow freely in low land and peat, and cuttings root in sand under a hand-glass.
Ochra, gland, decad, and leguminosee, a H. an. Eur. of common culture.
Ochtertyre, a seat in Perthshire, 7586.
Ockenden, — Esq., his work on gardening, page 1101. A.D. 1770.
Octomeria, gynan. monan. and orchidee, a S. peren. V. a parasite, which requires the same treatment as aires.
Ocymum, didyn. gynos. and labiatee, S. tr. bien, and an. and H. an. Ind. and China, of easy culture, and thrives in rich soil, as tender annuals.
Ocymum basilicum and minimum, the sweet basil, 4174.
Gleditsia oxyuon, polyg. segr. and coryntherfere, a G. tr. C. B. S. which grows in any light soil, and cuttings root readily under a hand-glass.
Ochetora, oenan. monog. and ognarenee, H. peren. bien. and an. A true monocotyl culture.
Ofelia, to propagate by, 1968.
Ofelia nut, hamiltoniaw olifera.
Oglyn, — see Sesamum.
Oglyn palmo, clai. guineenses.
Okeham Park, Surrey, 7398.
Oleaspy, Olaf, his works on gardening, page 1100.
Olef D., Olaf.
Old man's beard, — see Geropogon.
Oldenlandia, tetra. monog. and rubiaceae, a S. peren. and an. E. and W. Ind. of common culture.
Olea eurycarpa, the common olive, 5958.
Oleander, — see Nerium.
Oleaster, — see Elaeagnus.
Olive, — see Olea.
Olive bark-tree, buced bueras.
Olive-wood, — see Elaeodendrum.
Oliveria, panten. dig. and umbilliferenee, a H. an. Bagdad, — see Colnon culture.
Olyra, monoc. trian. and graninenee, a S. peren. W. Ind. a grass of easy culture.
Ombre, — see Ochrea. W. Worcester, cuttings, 7566.
Omphale, monan. monadel. and euphorbiaceae, a S. tr. Jamaica, which grows in light land, and cuttings root in sand under a hand-glass in heat, care being taken not to injure the leaves.
Oncidium, glynn. monan. and orchidee, S. peren. Ind. which require the same treatment as aires.
Onion, — see Allium.
Oniscus asellus, the wood-louse, 2273.
Onobloa, cryptog. ilices and filiceps, H. peren. Eur. and Amer. — see common culture.
Ononis, rest-harrow, diadel. decan. and leguminosee, G. tr. and peren. Eur. and C. B. S. which thrive in well drained peat, and are increased by seeds or young cuttings under a bell-glass in sand.
Onopordum, cotonothistyle, syninth. polyg. eucalyce, gynan. tr. bien. and an. Eur. of common culture.
Onopordum acanthum, 3560.
Onosma, monan. monog. and boraginee, a G. peren. and H. peren. Br. and S. Eur. which succeed best in rich, light soil, and are increased by cuttings under hand-glasses in sand.
Onosmodium, pentan. monogyn. and boraginee, a H. peren. N. Amer. which may be treated as ononos.
Operations of gardening, 1853; mechanical lifting, carrying, drawing, pushing, &c. 1856. to 1861.
Onions, laborious, on the soil, 1862; picking, digging, shovelling, excavating, levelling, marking with the line, trenching, ridging, forking, hoeing, raking, scraping, sweeping, wheeling, beating, rolling, sitting, &c. 1863. to 1881.
Operations, laborious, with plants, 1882; sawing, cutting, clipping, splitting, mowing, weeding, watering, &c. 1883. to 1895.
Operations in which skill is more required than strength, &c. transferring designs from ground to paper or memory, dimensions of simple objects, forms of surface, irregular figures, raised and depressed surfaces, delineating by ground-lines only, elevations, brochures, circular profiles, bird's-eye views, general views, &c. 1895. to 1912.
Operations, transferring figures or designs from paper to memory by plain surfaces, 1914; perpendiculars, angles, ovals, gardener's oval, a spiral line, centre of three points, polygons, polygonal gardens, fancytol figures, 1915. to 1924.
Operations of gardening; transferring figures and designs to irregular surfaces, 1925; straight lines, continuous lines, curved lines, level lines, &c. 1825. to 1920.
Operations for the arrangement of quantities, by trial and correction, by measure superficial, by solid measure, 1853. to 1892.
Operations, preparing designs into execution, 1940; removing surface encumbrances, smoothing surfaces, drawing off water by under-drains, by surface; forming excavations for retaining water, removal of earth, forming the bed or bottom, head, sluice; surfaces to imitate nature, artificial surfaces; walks, form of their surface, weeds, resistance of walks to animals, to weather, 1941. to 1968.
Operations of propagation, 1953; by seed, by bulbs, offsets, slips, division of the -plant, runners, suckers, twisters, twisting, ring-boring, and wire-layers, layering trees in the open garden, stools, Chinese layering, inarching, grafting,
theories of whip-grafting, cleft-grafting, crown-grafting, side-grafting, saddle-grafting, shoulder-grafting, root-grafting, terebration (laceratio, Lat. a boring with a Willie), stocks, free-growing stocks, and trained standards; grafting by budding, shield-budding, shield-budding reversed, scollop-budding, budding with double ligatures, stocks for budding, instruments and materials for, 2264 to 2266.

Operating for propagating by cuttings, 2053; choice, preparation, insertion, and management, 2064, to 2069.

Operations of rearing and culture, 2070.

Operations in sowing and planting, sowing, patches, broad-cast, planting, and watering, 2071 to 2078.

Operations in transplanting, 2077. The defoliation or partial removal of the plant, inserting, spade-planting, hole-planting, trench-planting, trenching in planting, slit-planting, holding in planting, digging into planting, cutting, frower-planting, dibble-planting, trowel-planting, planting with balls, planting by mudding in, paving, mulching, edgings, verges, turfing, transplanting stock, 2080, to 2108.

Operations in pruning, 2110; for promoting the growth and bulk of a tree, for lessening the bulk of a tree, for modifying the form of a tree, for forming dwarf standards, conical dwarfs, convex or conical dwarfs, horizontal dwarfs, spiral dwarfs, fan dwarfs, distals, natural dwarfs, pruning half and entire trees, thinning, retarding, or enlister, pruning for blossom-bud, pruning for the enlargement of the fruit, for adjusting the stem and branches to the roots, for renewal of the hedge, for pruning dwarfing, dwarfing stocks, for breeding herbaceous plants, seasons for pruning, summer pruning, 2111, to 2139.

Operations in training, 2140; object of training, modes of training trees with flexible stems, fan-training, horizontal training, horizontal training with screw stem, oblique training, perpendicular training, stellite training, open fan, wavy or curved training, vertical training, performing the operation on walls, sheds and nails, herbaceous training, 2141, to 2155.

Operations in blanching, 2156; by earthing, by tying together the leaves, by overlaying, by covering with utensils, 2157, to 2160.

Operations for inducing a state of fruitfulness, 2161; laying bare the roots, cutting the roots, notching the stem, partial decortication, stripping off pieces of the bark, ringing, renewal of the soil, bending down the branches, application to herbaceous plants, 2182, to 2173.

Operations for retaining vegetation, 2177; by the form of surface, by shade, by the ice-cold room, 2179, to 2180.

Operations for accelerating vegetation, 2181; by the form of surface, by shelter, by soil, by previous preparation of the plant, by inducing a state of dormancy, artificial green-houses, hot-houses, cold-frames, walls, by glass cases, by hot-beds, by walled pits, by hot-houses, temporary emplacement in hot-houses, permanent, 2182, to 2203.

Operations in hot and arid warm climates, 2201; general principles, green-house, dry-stove, bark-stove, watering, insects, 2205, to 2206.

Operations of protection from atmospheric influences, protecting by fronds and frond-like branches, by straw-rope, nets, canvass or bunting screens, mats, straw, and litter, oiled paper-frames, prescribing paper, preserving paper, parent covers, transparent screens, 2206 to 2218.

Operations relative to vermin diseases, and other casualities of plants, 2219; kinds of vermin, human enemies, vermin, hard vermin, soft vermin, gathered enemies, insects, coleoptera, hemiptera, lepidoptera, neuroptera, hymenoptera, diptera, apoder, worers, slugs, 2250, to 2279.

Operations relative to subduing vermin, 2276; insect vermin, preventative operations, palliative operations, destructive operations, 2277, to 2283.

Operations relative to diseases and other casualities, 2286 to 2288.

Operations of gathering, packing, preserving, and keeping, 2289; gathering fruits and seeds, preserving flowers or leaves, roots or bulbs, pears, and apples, sweating fruit, preserving seeds, roots, cuttings, grarts, roots, &c, 2290 to 2291.

Operations relating to the final products derived of gardens and garden-scenery, vegetable products, fruits, seeds, roots, stems and stalks, leaves, flowers, barks, woods, entire plants, 2325, to 2333.

Operations for the beauty and order of garden-scenery, 2343; color, propriety, decorum, neatness, importance of the profession of a gardener, &c, 2345 to 2373.

Opecularia, tetran. monig. and nyctaginaceae, a G. tr. N. 8. W., which thrives in loam and peat, and cuttings root freely in sand under a hand-glass.

Ophiopogon, snake's beard, hexandria monogyne. For the Japanese, and Smith, in the nursery, temporary and final distances, culture of the soil, of standard fruit-trees, only situation and soil, sorts, age of the plants, design for one to surround a kitchen-garden, 2548 to 2554.

Orchard, general culture and management of, 2610; manuring, cropping, watering, protecting and sheltering, clothing the stems, pruning aged trees, season of pruning, insects and diseases, gathering and storing orchard fruits, preserving, storing and packing for carriage, general culture and management, 2614, to 2643.

Orchardists, 2793.

Orchard, as a garden, its construction, 2171; for produce fruit, 2528.

Orchard, formation and planting of one subsidiary to the kitchen-garden, 2527; site, manure, screens, rotations of kinds, age of plants and the nursery, temporary and final distances, culture of the soil, of standard fruit-trees, only situation and soil, sorts, age of the plants, design for one to surround a kitchen-garden, 2548 to 2554.

Orchard, general culture and management of, 2610; manuring, cropping, watering, protecting and sheltering, clothing the stems, pruning aged trees, season of pruning, insects and diseases, gathering and storing orchard fruits, preserving, storing and packing for carriage, general culture and management, 2614, to 2643.

Orchardists, 2793.

Orchard, as a garden, its formation, 7455, and 7493; management, 7493.

Orchis, gynan. monan. and orchideae, G. and H. peren. Eur. and Barberry, which succeed best in a mixture of loam, peat, and chalk broken small; the best time to transplant them, as well as most other orchideous plants, is when they are growing; they are increased by seeds, which should begin as soon as they are ripe.

Ornmore Castle, a seat in Galway, 7612.

Orange, — see Citrus.

Oregny, ornamental, its construction, 2171; for producing fruit, 2528.

Ophrys, gynan. monan. and orchideae, G. and H. peren. Eur. and Barberry, which succeed best in a mixture of loam, peat, and chalk broken small; the best time to transplant them, as well as most other orchideous plants, is when they are growing; they are increased by seeds, which should begin as soon as they are ripe.

Ornmore Castle, a seat in Galway, 7612.

Orange, — see Citrus.

Oregny, ornamental, its construction, 2171; for producing fruit, 2528.

Orchard, general culture and management of, 2610; manuring, cropping, watering, protecting and sheltering, clothing the stems, pruning aged trees, season of pruning, insects and diseases, gathering and storing orchard fruits, preserving, storing and packing for carriage, general culture and management, 2614, to 2643.

Orchardists, 2793.
other plants. The common broom-rape, an. major, may be sown or planted at the root of the common broom, spartium, and the others at the roots of such plants as they are seen to affect in their wild state.

Orobus, bitter vetch, diadel. decan. and legumi-
nose, H. peren. Eur. of easy culture.

Orobus tuberosus, the tuberous-rooted bitter vetch, 4929.

Orontium, hexan. monog. and aroides, H. peren.

Amer. and Japan, which grow in light sandy soil, and are increased by division at the root.

Orpine, -- see Telephium.

Ortegia, trian. monog. and Caryophyllaceae, H. peren. Endr. which thrive in light rich soil, and cuttings root freely under a hand-glass.

Orthopogon, trian. dig. and gramineae, a s. tr. W. Ind. and Pakenham, which thrive in sandy soil, and are increased by cuttings.

Oryza, rice, hexan. dig. and gramineae, a s. an. Ethiopia, of easy culture as a marsh plant.

Oxaban, a seat in Derbyshire, 7577.

Oxax, P. A. Torren, and Captain Eckeburg, their voyage to China, page 1130. A. D. 1772.

Oxbeckia, octan. monog. and melastomeae, a s. bien. Ceylon, of common culture.

Oxier, -- see Salix.

Osmite, syngen. polyg. frustran. and corymbifereae, a G. tr. C. B. S. which grows well in light rich soil, and cuttings root freely under a hand-glass.

Ostings Hold, Nottinghamshire, 7576.

Osten, Van, his works on gardening, page 1129. A. D. 1703.

Ostospermum, syngen. polyg. necess. and corym-
biereae, G. tr. C. B. S. which may be treated as osmides.

Osterton House, Nottinghamshire, 7576.

Ostrya, hose-, dience. monog. polyan. and amen-
tecas, H. tr. Italy and N. Amer. which grow in any soil, and are increased by seeds or lay-
ering.

Ostroega tea, -- see Monarda.

Ostrois, poet's cassia, diac. trian. and santalaceae, a G. S. tr. Eur. which thrives in light soil, and ripened cuttings will root in sand under a hand-
glass.

Otaheite chestnut, inacarpus edulis.

Otaheite myrtle, securigeira nigita.

Othonia, ragwort, syngen. polyg. necess. and corym-
biereae, G. and F. tr. and peren. C. B. S. which grow in any light, rich soil, and cuttings root freely under a hand-glass.

Otto, Frederick, C. M. H. S., inspector of the botanic garden, Berlin, 219.

Owston, a seat in Yorkshire, 7582.

Oxyace, -- see Buphthalmum.

Oxy-eye daisy, chrysanthemum leucanthemum.

Oxy-lip, -- see Primula.

Oxy-tongue, -- see Ficris.

Oxys, -- see Sorex.

Oxys, saw-sorrel, dianvr. pentagyn. and gerani-
aceae, G. and H. peren. C. B. S. bulbs of easy culture.

Oxalis acetosella, the common wood-sorrel, 4075.

Oxto Garden, Oxford, 7559.

Oxfordshire, gardens and residences of, 7559.

Oxyanthus, pentan. monog. and rubiaeae, a s. tr. Sierra Leone, which thrives well in sandy loam and peat, and cuttings root in sand under a hand-glass.

Oxybophyllum, umbrell-a-wort. trian. monogyn. and nytigamineae, S. peren. and an. S. Amer. which grow in loam and peat, and are increased by young cuttings under a bell-glass in sand.

Oxyccoes, cranberry, octan. monog. and ericeae, a S. tr. and H. tr. Eur. and Amer. which require a peat soil, and moist situation.

Oxydendrum, macrocarpaeae, and palustris, 4708.

Oxylobium, decan. monog. and leguminoseae, G. tr. Austral. which grow in sandy loam and peat, and young cuttings root in sand under a hand-glass.

Oystelma, pentandria digynia and asclepiadeae, a S. peren. E. Ind. which thrives well in loam and peat, and cuttings root freely in sand under a hand-glass.

Oxytropis, diadel. decan. and leguminoseae, H. peren. and an. Eur. which prefers a light sandy soil, and are readily increased by seeds.

P.

Pachysandra, monoe-. tetran. and euphorbiaceae, a H. peren. N. Amer. which succeeds well in any common light soil, and increases freely by suckers from the roots.

Packenham Hall, a seat in Westmeath, 7665.

Paddock, puddock, or purrock, a country term, originally applied to a small space enclosed by pales from a park, for hounds to run matches in, now generally applied to the small grass enclosures commonly attached to a park, or kept in the hands of the resident on the demesne.

Pedaralia, monoe-. rubiaeae, a D. S. tr. China, a climber which thrives in loam and peat, and cuttings root readily.

Peonia, peony, polyan. dig. and ramunculaceae, the Chinese tree-peony, a F. tr. China, with numerous varieties, thrives in any rich, light soil; and ripened cuttings slipped off, and planted in the ground in a shady place, without cover, will root freely. The H. peren. Eur. requires a deep, rich, loamy soil, -- see 1639.

Peony, -- see Peonia.

Pine's Hill, a seat in Surrey, 7571.

Paisley, manufacturers, their gardens and florists' meetings, &c., 7658.

Palafoxia, monoe-. polyg. and malvasieae, a H. an. Perú, of common culture.

Paliade (pallisade, Fr.), any fence of poles, a palis; the term is generally used when an ornamental palisading is intended.

Palsely, Bernard de, a French author on gardening, page 1115. A. D. 1563.

Pallasia, syngen. polyg. frustran. and corymbifereae, a G. tr. which thrives well in any rich, light soil, and cuttings root freely under a hand-glass.

Palma Christi, -- see Ricinus.

Panax, polyg. dier. and arileae, S. tr. Amer. and China, which thrive well in light loam, and cuttings root readily in sand under a hand-glass; the H. peren. grow in similar soil, and are increased by seeds set to rooting in the sand at the root.

Pancreatium, hexan. monog. and amarillideae, S. and G. peren. and H. peren. Eur. Amer. and India, which thrive in light loam and vegetable mould, with little water when not in a growing state.

They are increased by seeds and suckers.

Pandanus, screw-jine, dicac. monan. and pandana-
cele, S. tr. Ind. and N. S. W. which thrive in

loamy soil; but rarely produce growths which admit of removal for propagation.

Panicum, -- see Panicum.

Panicum, panic-grass, trian. dig. and gramineae, S. tr. and bien. and H. peren. and an. Ind. Amer. and Eur. grasses of common culture.

Panneper, a term signifying the feed which swine or cattle may derive from the mast, acorns, or herbage of woods.

Panning, forming a pan or saucer-like hollow round newly planted trees, to receive and retain water, 2098.

Pansharper, a seat in Hertfordshire, 7544.

Panton House, Lincolnshire, 7577.

Papaver, poppy, polyan. monog. and papaveraceae, H. peren. Eur. of easy culture.

Papaw-tree, -- see Carapa.

Papaw-tree, Acer pseudobalanus, morus papyrifera.

Papilio, the butterfly, a lepidopterous insect, 2251.

Pappilio machaon, 6194.

Parasitic plants, their culture and management, 6736.

Parasitic plants, such as root into other living plants, and derive their nourishment from them; some root into the stem or branches, as viscus, the mistletoe; others attach themselves to the root, as hyphates, and some of the indocordae and acridae will grow either on living or dead trees.

Pardanthus, trian. monog. and iridesceae, a G. peren. Chi bi, a bush which is treated as Ixia.

Parke Hall, a seat in Sussex, 7561.

Pariana, monoe-. polyan. and gramineae, a S. tr. Cayennae, which grows in loam and peat, and cuttings root in sand under a bell-glass.

Parietaria, pollin. polyg. monoe. and urticaceae, a S. peren. and an. and H. peren. Eur. and India, of easy culture in light soil.

Amer. which succeed best in peat soil and a moist situation, and are increased by seeds. Peel Hall, Cheshire, 1590.

Peganum, dodec. monog. and rutaceae, H. peren. Eur. which thrive in rich, light soil, and cuttings root freely under hard-glasses. Pekra, a seat near Moskwa, 262. Pelargonium, stork's bill, monadelph. heptan. and geniculata, G. tr. geniculata, and an C. B. S. and some S. tr. and peren. all of easy culture in any rich, light soil, the succulent sorts well drained and not fertilized, 603.

Félice, M. de St. Maurice, a French author on gardening, page 1116. A. D. 17\text{--}.

Pelliontis, hexan. monog. and \ldots\ldots., S. peren. E. in peat root well and in loam, and are increased by dividing at the root. Pellepoir-Saune, M., his work on gardening, page 1122. A. D. 1813.

Peltophyllum, bell-glass, Peltaria. Peltaria, tetrad. silic. and cruciferae, a H. peren.

Austral. of common culture. Pembroke, gardens and residences of, 7609. Penza, teucrium and Jasminaceae, G. tr. C. B. S. which thrive in loam and peat, with the pots well drained, and young cuttings root without difficulty in sandy soil and sand.

Pendervase, a seat in Cornwall, 7601. Penguicul, a seat in Flintshire, 7606. Penicillium, pol. monog. and Gramineae, a S. and H. an. Beech, an Ind. of common culture, 7607.

Penthorum, decan. pentag. and S. peren. P. five-petalled, which grows freely in light, sandy soil, and is readily increased by dividing at the root, or by young cuttings under a hothouse. Pentro, a seat in Pembroke, 7609. Pentstemon, didyn. angios. and bignoniacceae, a F. tr. and H. peren. N. Amer. which grow in light, rich soil, and is increased by dividing at the root. Pepper, see Piperc. Pepper Harrow, a seat in Surrey, 7528.

Pepperwort, capsas., P. Pepworth, see Lepidium. Pericallis, monog. super. and corymbifereae, a H. peren. P. P. which grows well in rich, light soil, and cuttings root freely under a hothouse.

Pepis, water-purslane, hexan. monog. and salicaceae, a H. an. Brit. a marsh plant of easy culture. Peper, see Piperc. Pepper Harrow, a seat in Surrey, 7528.

Pepperwort, capsas., P. Pepworth, see Lepidium. Pericallis, monog. super. and corymbifereae, a H. peren. P. P. which grows well in rich, light soil, and is increased by dividing at the root. Perfect, Thomas, his works on gardening, page 1102. A. D. 1779.

Perforated piers, piers for fruit-tree walls, the projecting part of which are perforated to admit of training the shoots through the pier, instead of stopping them there, or bending them over it. It is an ingenious mode, but the rounded pier (1727, \textit{ibid.}, p. 172) which is practicable, is to be preferred, as more readily admitting the taking down and replacing of the branches at the pruning season.
are increased by cuttings under a hand-glass or seeds.

Phlox, lychnidea, pent. monog. and polyanthroseae, | H. peren. This prefers a loamy soil, and is increased by cuttings or dividing at the roots.

Phlox paniculata, dixie, trian. and palmeae, S. tr. and G. tr. Levant, C. B. S. and E. Ind. which require a light soil, and are increased by seeds.

Phlox Park, Dublin, 7633.

Phormium: 1. Bright, easy to propagate, monog. and asphodelaceae, a G. peren. N. Zeland, which thrives in any light, rich soil, and is increased by offsets from the roots.

Phryma, didym. gymnos. and labiateae, a H. peren. N. Amer. which thrives well in rich, light soil, and cuttings root freely in sand under hand-glass.

Phyllum, monan. monog. and cannae, S. peren. E. Ind. which thrive in rich, light soil, and are increased by dividing at the root.

Phylica, pentandria monogynia and rhamnaceae, G. tr. C. B. S. which grow best in sandy peat, and young cuttings root readily under a bell-glass in sand.

Phyllanthus, monac. monad. and euphorbiaceae, S. tr. and an. chiefly W. Ind. which succeed well in loam and peat, and cuttings root freely in soil under a hand-glass.

Phyllis, pentan. dig. and rubiaceae, a G. tr. Canar. which grows in loam and peat, and cuttings root in sand under a hand-glass.

Phyllopsoma, hexan. monog. and asphodelaceae, a S. tr. Bourb, which thrives well in sandy loam, requires very little water, and is increased by suckers.

Phys. des Arts, Dulhame sur le Physique des Arbes.

Physalis, winter cherry, pentan. monog. and solanaceae, S. tr. and G. tr. and H. peren. and an. chiefly N. Amer. which thrive well in rich, light soil, and are increased by young cuttings under a hand-glass or seeds.

Physic-gardeners, herbalists, or simplicists, 7464.

Physic-mut, see Jatropha.

Physic-mutes, or gardeners, their formation, 5360.

Physutena, rampon, pentan. monog. and campulaceae, a G. peren. and H. peren. and a bien. chiefly Europe, which thrive in rich, light soil, do well in pots, and are increased by dividing at the root: the garden rampon is a campanula.

Phytolacca, dodec. decag. and chenopodiaceae, S. tr. Amer. and Amer. which thrive well in loam and peat, and are increased by cuttings or seeds.

Phytolaccaceae, 4196.

Phyllanthus, monac. monad. and euphorbiaceae, S. tr. and an. chiefly W. Ind. which succeed well in loam and peat, and cuttings root freely in soil under a hand-glass.

Picking, 1296.

Picking, 1863.

Pierandria, dioec. pentan. and .........., a S. tr. Amer. which thrives in loamy soil, and large cuttings root freely in sand under a hand-glass.

Pieridium, syngen. polyg. squam. and eichoreaceae, a H. peren. and an. France and Barb. of common culture.

Picris, syngen. polyg. squam. and eichoreaceae, H. peren. and an. chiefly Europ. of common culture.

Picris hieracioides, hawkweed-like ox-tongue, 4951.

Pitton, a seat in Pembrokehire, 7609.

Pierard, Charles Francis, his work on gardening, page 1122. A. D. 1839.

Pierrefield, a seat in Monmouthshire, 7567.

Pier尾, Louis-elle, his works on gardening, page 1106. A. D. 1772.

Pigeon-house, see Columbarium.

Pigeon-houses of Persia, 496.

Piggott, Richard, his work on gardening, page 1114. A. D. 1820.

Pileweed, House, Hampshire, 7594.

Pilewort, sicaria vernia.

Pilwort, pilularia globuliferia.

Pilularia, pilwort, cryptog. hydrophyte and mariesiaceae, H. peren. Brit. with an aquatic common culture.

Pimelea, dixie, monog. and thymelaeaceae, G. tr. Austral. which thrive best in loamy peat, and young cuttings root in sand under a bell-glass.

Pimpemelle, see Anagallis.

Pimpinella, burnet-saxifrage, pentan. dig. and um.
bollifereae, H. peren, and am. chiefly Europ., which grows in rich, light soil, and is increased by seeds.

Pimpinella anisum, the anise, 4213.

Pimpinella, pentan. monog. and E. baldianca, a F. tr. Genus, which grows in sandy loam and peat, and cuttings root in sand under a hand-glass.

Pimedont, Ipomolito, his works on gardening, page 1129. A.D. 1818.

Pimenta, 514. — see Bromelia.

Pine-tree, — see Pinus.

Pinery, its construction, 2645; general culture and management, 2597.

Pinguicula, butterwort, dian. monog. and lenticularis, a G. an. Carolin. and H. peren. Europ., which grow naturally in swamps, and succeed in pots of any species of sphagnum. With a little peat at the bottom, like drosera; they are increased by offsets from the heart of the plant, and from seed.

Pinguicula vulgaris, the common butterwort, 4320.

Pink, — see Dianthus.

Pinking House, East Lothian, 7219.

Pine, the pine-dr and larch, monoc. monad. and confereae, a F. tr. Amboya, G. tr. E. Ind. and H. tr. Eur. and Amer. ; the S. species succeed in light, loamy soil, and ripened cuttings taken off at a joint will root, though not readily, in sand under a hand-glass; the G. species require the same soil, and roots more freely; the H. species grow in light soil, and are commonly increased by seeds.

Pinus abies, the spruce-dr, and other firs in common cultivation, 7058, to 7087.

Pinus cedrus, and P. larix, the cedar-larch, and common larch, 7051. and 7033.

Pinus sylvestris, the Scotch or wild pine, and the other pines in common cultivation, 7101-7121.

Piper, pepper, dian. trig. and urticulas, S. tr. chiefly climbers, peren. and an. W. Ind. mostly succulents which grow in sandy loam and peat, and are readily increased by cuttings and suckers.

Pipewort, eric caulon septangulares.

Placera, syngon. polyg. aequal and corymbifereae, a G. peren. Mex. which grows freely in any light, rich soil, and cuttings root readily under a hand-glass.

Piscidea, Jamaica dogwood, diadel. decan. and leguminoseae, a S. tr. W. Ind. a strong fast-growing plant in sandy loam, and cuttings root in sand under a hand-glass.

Piscinaria, 1767.

Pisces, or ex pines, (ex pire or en pire), in the worst manner, that is, as a last resource, a mode of building mud walls, 1564.

Pisum, heptan. monog. and nasi caugiae, S. tr. Vic. a species of a G. tr. partly a G. tr. in loam and peat, and cuttings root in sand under a hand-glass.

Plataelia-tree, — see Pterostigma.

Platiflora, diece. pentag. and terebintinaceae, G. tr. Barb. and H. tr. S. Eur. the G. species grow in loam and peat, and ripened cuttings root in sand under a hand-glass. the H. tr. rather tender, but grow in common soil, and are increased by layers or cuttings under a hand-glass in sandy soil.

Pismium maritimum, the sea-pea, 4309.

Pismium saltatile, the garden-pis, 3597; to force the pea, 3539.

Pit, a structure with a glass cover or roof, used as a hot-bed, for plants of earth, of fire, and of puppy plants, M’Phail’s pit, Alderstone pit, with rising frame, West’s pit, &c. 1540. to 1544.

Pit, in the conservatory, the bed of earth in which the plants are planted, covering the principal part of the area of the house.

Pit of a stove or hot-house, an excavation in the moist or dry, containing inflammable materials in order to supply bottom heat.

Pitcairnia, hexan. monog. and bromeliaceae, S. tr. W. Ind. and S. Amer. which flower freely in light, rich soil, and are increased by suckers from the root.

Pitcheer-plant, nepenthis distillatoria, 293.

Pitlinstorm, a seat near Worcester, 352.

Plante-tree, — see Platanius.

Plank-plant, bossiaea scelopodarium.

Planter (Scotch), a maker of plans, — see Horticultural Architect.

Plans for improving country-residences, 7364; how to form, 7364; important uses of, 7569; how to carry into execution, 7370.

Plans of gardens and garden objects, how to form, 1892; to transplant them to ground, 1913; to execute them, 1940.

Plant, grass, — Histoire des Plantes Grasses. Par A. P. Decembre.

Planting package, different sorts of, 1404.

Plantage, plantain, tetran. monog. and plantagineae, a G. tr. and bien. C. B. S. and H. peren. and an. chiefly Eur. all of very easy culture in common soil.

Platango comosus, star of the earth, 4315.

Plantain, — see Plantago.

Plantain-tree, — see Musa.

Plantations, neglected, to improve, neglected hedge-rows, hedge-row timber, neglected ornamental plantations, 6291. to 6294.

Plantations, ornamental, their formation, 6532; form, extent, disposition, general form, situation, arrangement of species, size of plants, 6533. to 6576.

Plantations of trees, their uses, as to shelter and climate, improving soils, shade, separation, seclusion, distinction, appropriation, concealment, to heighten and adorn objects, direct the eye to objects, render indifferent objects agreeable, enhance the value of landed property, afford profit, 6703. to 6712.

Plantations, their different kinds, group, clamp, woods, copse woods, 6510. to 6514.

Plantations, their disposition in the ancient style, 7210; in the modern style, 7214.

Plantations, useful, their formation, 6815.; preparing the soil, form, enclosing, fences, species of tree, mixture, whether to be sown or planted, disposition of, the number of plants and distance, size of the plants, seasons for planting, operations of, 6816. to 6851.

Plantations, useful and ornamental, their culture and management, 6874.; culture of the soil, filling up blanks, pruning, for utility, for ornament, seasons for, for implements for, resinus trees, non-resinous trees, and the head, wind trees, pruning for bends, coppices, osier rolls, strips and screens, trees for shade, trees in parks, in pleasure-gounds and lawns, thinning, 6878. to 6913.

Plantations, valuation of, 6915.

Planting, — see Arboriculture.

Planting, different modes of performing the operation, 2077. to 2109.

Planting in horticulture, operation of, by pitting, by the diamond dibber, by the planter’s mattock, by the planter, by slitting, 6841. to 6851.

Plants, — see Vegetables.

Plants, as indicative of soils, list of, 1096.

Plants used as preserves and pickles, 4258.

Plants used in tarts, confectionary, and domestic medicine, 6916.

Plas Newydd, a seat in Anglesea, 7603.

Plat (plat, Fr. flat), a piece of ground of determinate form, small compared with a field, but larger than a border, bed, or stripe, — see Plat.

Plat-band (plat bande, Fr.), a border round a flat.

Platanius, plane-tree, monoe. polyan. and amentaceae, H. tr. Levant, and N. Amer. handsome timber trees which grow in common soil, and are propagated by layers and cuttings.

Platt, Sir John, his works on gardening, page 1099. A.D. 1594.

Plattes, Gabriel, his works on gardening, page 1100. A.D. 1635.

Platylobium, flat pea, diadel. decan. and leguminoseae, G. tr. Austral. which grow in sandy loam and peat, and cuttings root in sand under a hand-glass.

Plaz, Anthony William, his works on gardening, page 1123. A.D. 1764.

Pleacher (from plateo, to plait or weave), an arbormaker. — see Copiarus.

Pleasure-ground, garden-scenery devoted to show and recreation, generally placed near the house, and consisting of lawn, shrubbery, flower-gardens, walks, water, seats, &c.

Plectranthus, didym. gymnos. and labiateae, a S. tr. an. and G. tr. and a bien. Africa and E. Ind. of easy culture in light soil.
Electroota, pentan. monog. and rhamneece, a G. tr.

C. B. S. which thrives in loam and peat, and ripened cuttings root under a hand-glass in sand.

Picea, the Norway pine, juncece, a G. peren. Carol. of common culture.

Phayck, J. J., his work on gardening, page 1125.

Philec, limb, icones Plantarum, &c., or figures of plants, &c. by Dr. J. J. Plueck.

Pleurothalis, gynan. monan. and orchideae, a S. peren. W. Ind. A parasite which requires to be treated as aëricce, &c.

Placra, pentan. monog. and rubiaceae, a G. tr. Cannar. which grows in loam and peat, and ripened cuttings root in sand under a hand-glass. Plot (from computer, to contrive or design), a plot laid out in figures or contrivances, as a parterre.

Ploughed gardens and their management, 7433, to 7493.

Plunkman's spikenard, see Baccharis.

Pluk. phlyt., L. Plukennett Phytography.

Plukenedia, monec. monad. and euphorbiaceae, a S. tr. W. Ind. A climber which grows best in loamy soil, and cuttings root in sand under a hand-glass.

Plum-tree, see Prunus.

Plumeria, pentan. dig. and apocynce, S. tr. E. and W. Ind. which flower freely in light, loamy soil, and require but little water, especially when not in a growing state. Plant cuttings laid to dry for a considerable time, and stuck in the tan, will root freely.

Plumptre, scenery of, in Yorkshire, 7592.

Pluviometer, or rain-gauge, 1288.

Poa, meadow-grass, trian. dig. and gramminece, S. peren. and on. E. Ind. and H. peren. and an. E. Ind. and N. Amer. requires the easier culture.

Podalyria, decan. monog. and leguminoseae, G. tr. C. B. S. pretty plants which grow in loam and peat, and are increased by ripened cuttings in sand, under a hand-glass, or by seeds.

Podocarpus, monec. monadel. and coniferece, G. tr. China and C. B. S. which grow in loam and peat, and ripened cuttings root readily under a hand-glass in sand.

Podolepis, syngyn. polyg. super. and corymbiferece, G. tr. Amer. Austrail. which thrive well in loam and peat, and are increased by dividing at the root.

Podolobium, decan. monog. and leguminoseae, a G. tr. Amer. A plant which grows in loam and peat, and young cuttings may be rooted in sand under a bell-glass.

Podophylum, duck's-foot, polyg. and portulaceae, W. Ind. A plant which thrives in rich, light soil, and is increased by dividing at the root.

Peter, — I'aine, his works on gardening, page 1129. A.D. 1773.

Poet's cassia, osyris alba.

Pogonia, gynan. monan. and orchideae, a G. peren. and In. peren. N. Amer. which grows best in peat, and is increased by offsets from the bulbs.

Poisunia, Barbadoes flower-fence, decan. monog. and leguminoseae, S. E. Ind. which require a strong heat to make them flower. They grow in loam and peat, and are increased by cuttings in sand, under a hand-glass, or by seeds.

Potatis —, his work on gardening, page 1121. A.D. 1804.

Poison-nut, strychnos nux vomica.

Populus, aspen, rhus toxicodendron.

Poisonous plants, of common occurrence, in Britain, 4234.

Polemonium, Greek valerian, pentan. monog. and polyanthaceae, H. peren. N. Amer. and Brit. of the easiest culture.

Polosden, a seat in Surrey, 7527.

Pollenites, tuberose, hexan. monog. and hemerocalliceeae, a G. peren. E. Ind., 6328.

Policie, the Scotch term for pleasure-ground.

Polychest, the English manug. and fireman, 7527.

Polichius, monan. monog. and chenopodeae, a G. bien. C. B. S. of easy culture.
GENERAL INDEX.

Potentilla anserina, the wild tansy or goose-grass, 4307.
Potter, sanguisgirius, the common burnet, 4372.
Postos, tetran. monog. and aroides, S. peren. W. Ind. and a H. peren. N. Amer. all of which thrive well in loam soil, and are increased by dividing the roots, or by seed.
Potsdam, gardens of, 238.
Powell, see C. E. E. Pemberton, 7600.
Powe, Anthony, Esq. his work on gardening, page 1107. A. D. 1799.
Powerscourt, a seat in Wicklow, 7674.
Poynton, a seat in Montgomeryshire, 7677.
Poynton, a seat in Cheshire, 7690.
Pozzi, George, his works on the vine, page 1126.
A. D. 1810.
Praslin, didyn, gymnos, and labiateae, F. tr. S. Eur. which thrive in rich light soil, and young cuttings root under a hand-glass.
Praslin, formerly Vaux le Vicompte and v. le Vil-lars, now Vauosome Praslin, a seat near Paris, the first attempt of Le Nôtre’s to lay out grounds.
Preserving vegetables, operation for, 2389.
Preston Hall, in East Lothian, 7619.
Prestwood, a seat in Staffordshire, 7570.
Prestwood Hall, Leicestershire, 7573.

Prop for plants, different kinds of, used in gardening, 1570.
Proposis, decan. monog. and leguminoseae, a S. tr. E. Ind. a prickly plant of which the pods are eaten as a spice in India; it grows in loam and peat, and cuttings root in sand under a hand-glass.
Prospect towers, their use in gardening, 1806.
Prosopis, monog. and protocaceae, a G. tr. N. S. W. a beautiful plant which thrives in loam and peat, and cuttings root in the same soil under a hand-glass.
Protocaceae, tetran. monog. and proteaceae, G. tr. C. B. S. magnificent plants which grow best in light turfy soil, with one third fine sand; the pots well drained, and furnished with a stratum of shers or gravel; care must be taken not to let the plants drop for want of water, as they will soon recover. Ripened cuttings taken off at a joint, and pared quite smooth, and thinly planted in pots of sand, will root under a hand-glass, but not plumped; dump must be avoided by wiping the glasses frequently.
Protecting vegetables, 2306.
Pruning, — See dibber, dibby, gymnos, and labiateae, H. peren. and an. N. Amer. and Eur. which thrive in light rich soil, and are increased by dividing at the root.
Pruning, — See dibber, dibby, 4332.
Pruning, science of, 2110.
Prunus, the plum and cherry, icos. di-pentag. and rowan, and the C. tr. F. W. and E. Ind. and H. tr. Eur. and N. Amer. The G. and F. sp. grow in loam and peat, and cuttings root in sand under a hand-glass: the H. sorts grow in any loamy soil, and are increased by all the modes of propagating trees.
Prunus avium, the jean, 4571.
Prunus cerasus, the cherry, 4571; cherry-house, 5741.
Prunus domestica, the common plum, 4520; to force the cherry, 3117.
Prunus spinosa, the sloe, 4765; P. padus, the bird-cherry, 4763.
Psidium, gen. polyg. necess. and corymboseae, a S. tr. Maur. which grows freely in rich light soil and cuttings will root readily under a hand-glass.
Psidium guava, icos. monog. and myrtaceae, S. tr. W. Ind. grown there for their fruit: here they thrive in loamy soil and pineapple, and rich fruit soil; they are increased by cuttings in sand under a hand-glass, or by layers.
Psidium guajava, peren., Psidium guajava, fc. 5092.
Pisonia, cryptog. stachyopt. and lycopodiacea, a S. peren. W. Ind. a fern which grows in loam and peat, and cuttings will root under a hand-glass in sand.
Psoralea diadelph. decan. and leguminoseae, a S. bien. and G. tr. and peren. chiefly C. B. S. which grow freely in loam and peat, and are increased by cuttings in sand, or printed on a bell-glass, or by seeds, which they ripen abundantly.
Psoralea esculenta, the bread-root, 4533. 6031.
Psychotria, pantan. monog. and rubiaceae, S. tr. W. Ind. which thrive in loam and peat, and cuttings root in sand under a hand-glass.
Pterocarpus, diadelph. decan. and leguminoseae, a S. tr. E. W. Ind. which thrive in light loamy soil, and cuttings not deprived of their leaves, root in sand under a hand-glass.
Pteronia, synygen. polyg. equal. and caryophyllaceae, G. tr. which thrive in loam and peat, and cuttings root freely under a hand-glass.
Pterospermum, monat. dodec. and malvaceae, G. tr. E. Ind. which thrive well in light soil, and cuttings not deprived of their leaves, root freely in sand under a hand-glass.
Pterostylis, genan. monan. and orchideae, a G. peren. S. W. which thrives in sandy loam and peat, without much water after it has done flower-
Pteropodium, genan. monan. and orchideae, a G. peren. C. B. S. which may be treated as ptero-
stylos.
Pukane-qua, villa of, near Canton, 676.
Public gardens, to lay out, 7312.
Public laws relative to gardening, 7700.
Public parks, their formation, 7313; management, 7492.
Public squares, their formation, 7319; management, 7491.
Puccoon, sanguinaria canadensis.
Puddling or muddling the roots of plants, 6849.
Pudica hold water, 7190.
Pulhawa, a seat near Lublin, in Poland, 283.
Puzzlein, Samuel, M. A., his work on gardening, page 1193. A. D. 1801.
Pulmonaria, lungwort, pantan. monog. and boraginacea, H. peren. Eur. and N. Amer. of easy cult.
through in light soil.
Pulmonaria, lungwort, polyan. polyg. and ranun-
Epulmonaria, H. peren. Eur. which grow best in light sandy soil, and may be increased by division at the root.
Pulmonaria, decan. monog. and leguminoseae, S. tr. Austral. which grow in sandy loam and peat, and cuttings root readily under a bell-glass in sand.
Quaking grass, — see Briza.
Quassia, decan. monog. and magnoliaceous, S. tr. W. Ind. which grows freely in loam and peat, and ripened cuttings, taken off at a joint, not defoli- ated, root readily in sand under a hand-glass.
Queenby Hall, Leicestershire, 7573.
Queensborough, a seat decan. away, 7672.
Quever, J, — his works on gardening, page 1120.
A. D. 1800.
Quercitrin, the dyer's oak, 7072.
Quercus, oak, moneyn. polyan. and amameetia, H. tr. N. Amer. and Eur. which grow in loamy soil, and are increased by seeds, and some sorts by layers and grafting.
Quercus cerris, the locumbe oak a variety of the Turkey oak, 7071.
Quercus robur and pedunculata, the common oak, 7070.
Queria, trian. monog. and Caryophylleace, a H. an. Spain, of common culture.
Quillwort, Isoetes linzae, a H. tr. Quince-tree, — see Cydonia.
Quinunx, a mode of planting or disposing of objects, 7073.
Quinteine, Jean de la, his writings on gardening, page 1116. A. D. 1666.
Quisqualis, decan. monog. and combretaceae, S. tr. E. R. Pombers, 7103.
Rabbi Castle, Durham, 7385. 
Radiola, all-seed, tetran. tetrag. and sempervirens, a H. an. Brit. of easy culture.

Radish, — see Raphanus.
Radiorhiza, gardens of, 7610.
Rafflesia arnoldii, and R. horsfieldii, 6757.
Rafnia, decid. decid., and humming, a G. bien. C. B. S. of common culture.
Ragged Roof, lynchnis floraecull.
Pumpkin, see Cucurbita, and cucurbitaceae, a H. tr. in rich soil, and cuttings root under a hand-glass.
Rains, or railings, used in gardening, 1803, and 6092.
Rain-gauge, or piolometer, 1286.
Rainham, a seat in Norfolk, 7554.
Raiith, a seat in Fife, described, 7635.
Rajania, diec. hexan. and discoerese, a S. peren. W. Ind. which thrives well in rich loam, and is increased by dividing at the roots.
Rank (raceu, Fr.), different kinds of, 1314.
Raking, — see Arrangement.
Ramonda, pentan. monog. and solanaceae, a H. peren. Pyrenees, which thrives in dry rockwork or in pots, in loam and peat, and is increased by dividing the root, or by seeds.
Ramoon-tree, — see Trophis.
Rampion, — see Campanula and Phyteuma.
Ranait, James, a Scotch landscape-gardener, 583.
Ramson, allium urisinum.
Rana arborea, or tree-frog, 6086.
Randia, pentan. monog. and rubiaceae, S. tr. Afr. and W. Ind. which grow best in sandy loam and peat, and cuttings root in sand under a hand-glass, in moist heat.
Ranft, J. F., his works on gardening, page 1125.
A. D. 1788.
Ranaiebens, his essay on gardening, page 1127. A. D. 1817.
Randunculus, crowfoot, polyg. polyg. and ranuncu- laceae, H. peren. bien. and an. of easy culture in common garden-soil, some requiring a moist situation, and others, as R. aquatilis, to be planted in shallow water.
Randunculus asieicus, the garden ranunculus, 6256.
Rape, brassica napus.
Raphanus, radish, tetard, silic. and cruciferese, a H. peren. bien. an. and Eur. of easy culture.
Raphanus, sativus, the garden radish, 3574; to force the raics, 3405.
Raphis, René, a French writer on gardening, page 1116. A. D. 1665.
Rapietra, a genus of, and silic. and cruciferese, H. an. Egypt and Eur. of common culture.
Rarities, as garden decorations, 1841.
Raspberry, rubus idaeus, 4936. — see Rubus.
Rastilhon, a seat in the county of Cork, 7665.
Rathfranham Castle, a seat in the county of Dub- lin, 7653.
Rea, Filippo, his works on gardening, page 1128. A. D. 1809.
Rea, John, gent., his works on gardening, page 1101. A. D. 1655.
Read's garden syringe, 1419.
Reauumuria, polyan. pentag. and sciochex, a F. tr. Syria, a handsome flowering plant in sandy loam and peat, and young cuttings root under a hand-glass.
Red Castle, a seat in Ross-shire, 7647.
Red cereus, jasperm virginiann.
Red Rose, a seat in Hampshre, 7594.
Red spider, — see Acratus.
Redgrave Hall, Suffolk, 7652.
Reeds, — see Arundo.
Reed's coverings, of, used in gardening, 1520.
Regent's Park, London, 7313.
Regina Claudia (Reine Claudia, Fr.), Queen Claudine, a plum, the green gage of this country, — see Plums, low in loam and peat, and root freely in sand under a hand-glass.
Relf, John, his works on gardening, page 1101. A. D. 1683.
Relhania, syngen. polyg. super. and corymbiferese, a G. tr. C. B. S. which grows in rich, light soil, and cuttings root under a hand-glass.
Religions, its influence on gardening, 512.
Rendome, a seat in Gloucestershire, 7593.
GENERAL INDEX.

Rendella, Prospera, his work on gardening, page 1198. A. D. 1629.
Rendlesham Hall, Suffolk, 7592.
Renshawshire, gardens, 7528.
Repton, Humphrey, Esq. his writings on gardening, page 1111. A. D. 1795.
Reseda, dodex. trig. and caparidice, G. tr. Spain, G. S. H. and H. peren. lien. and Eur. all of easy culture.
Reseda odorata, the mignonette, 6494; tree-mignonette, 6497.
Rested, the formation and laying out of, 7250; mansion and demesne, villa, farm, hall, ferme, orne, temporary residences, cottage orne, etc.
Rhee,fections, house with carriage-entrance, house with covered entrance, house and conservatory, house and flower-garden-entrance, house and French parterre, covered for garden, farmer's garden, laborer's cottage and garden, 7271. to 7311.
Resinous timber-trees, the most useful sorts described, 7639.
Reseca, Jean Baptiste Deschines de, a French author on gardening, page 1117. A. D. 1716
Ress-harrow,—see Ononis.
Restic, rhubarb, green, pin, and restisaceae, a G. peren. C. B. S. which thrive in peat soil, and is increased by dividing at the root.
Retarding vegetation, operations for, 2177.
Retea, a dividing operation, 2177.
Retzia, pentan. monog. and cono vouloaceae, a G. tr. C. B. S. which thrive in any rich soil, and cuttings root freely in sand under a hand-glass.
Rhagadiolus, Rhagodia, Rhodiola, Rhododendron, Ribes, Phillipine, and other species, which thrive in moist places, and thrive in loam, and are increased by suckers.
Rhedin al., Hortus Indicus Malabaricus, Adonatus per Honr. van Rheede van Drakenstein.
Rhein, rhubarb, oncean. trig. and polygoneae, H. peren. Eur. and Asia, of easy culture.
Rheum rhaponticum, common culinary or tart-rhubarb, 4196; to force rhubarb, 4033.
Rheum, ornan. monog. and melacace, a S. tr. S. Amer. and F. and H. peren. N. Amer. beautiful plants which grow best in peat soil, and are readily increased.
Rhinanthus, yellow rattle, didyn. angios. and scrophularineae, a H. an. which prefers a peat soil, and a moist situation.
Rhispalp, lecanon. monog. and cacteae, D. S. tr. W. Ind. and S. Amer. succulents of easy culture.
Rhodiola, rosea-root, dioec. octan. and sempervirec, a H. peren. Brit. of easy culture in dry soil.
Rhodendron, decan. monog. and rhodacaceae, G. F. and H. tr. chiefly N. Amer. which prefer peat soil, and are increased by layers or seeds, 9565.
Rhodora, decan. monog. and rhodacaceae, a H. tr. N. Amer. which may be treated like rhododenron.
Rhododendron, tetran. monog. and proteaceae, S tr. which grow in sandy loam, with a little peat, and cuttings root in sand under a hand-glass.
Rhubarb,—see Rheum.
Rheum, which prefers a peat soil, and thrives in loam and sand, to increase cuttings, and cuttings root freely under a hand-glass, is increased by layers or seeds, and cuttings are increased by cuttings of the roots, or layers.
Rhynchospora, trian. monog. and cyperecaceae, H. peren, till/grass, or cereale culture.
Rb-grass, planctano lanceolata.
Ribes, the currant and gooseberry, pentan. monog. and cacteae, H. tr. Eur. and N. Amer. of easy culture.
Ribes grossularia, the gooseberry, 4634.
Ribes nigrum, the black currant, 4678.
Ribes rubrum, the red currant, 4690.
Ribes quinaturn, the acid or tree currant, 4679.
Riblestown Hall, Yorkshire, 7592.
Rice,—see Oryza.
Richard, —his works on gardening, page 1121. A. D. 1802.
Richardia, hexan. monog. and rubiaeaceae, a S. tr. Vera Cruz, which grows in loam and peat, and cuttings root in sand under a hand-glass.
Richmond Park, Surrey, 7529.
Richinus, palm Christii, moncece, monad. and euphorbiaceae, S. bien. and an. G. tr. E. Ind. and Africa, of easy culture: the S. tr. species root from cuttings taken off at a joint, and planted under a hand-glass.
Ribat, terraced, and cruciferece, a H. an. Egypt, of common culture.
Ridgind, 1871,—see Operations.
Riding, a carriage-road or indicated path fit for horses and carriages, made for the display of the scenery of a residence, 7295.
Riedel, J. C., his works on gardening, page 1123. A. D. 1731.
Riefenbarn, F., his works on gardening, page 1127. A. D. 1810.
Rills, how to form or improve in garden-scenery, 7282.
Ring-fence,—see Kitchen-garden.
Ringing for maturation of fruits, 2168.
Ringing to induce a state of fruitfulness, different modes of using, 3576; for the display of the scenery of a residence, 7297.
Rivenhall Place, a seat in Essex, 7104.
Rivers, to improve in garden-scenery, 7233; to imitate their effects on plants in an aquarium, 4169.
Riviere, de la, and Du Moulin, their work on gardening, page 1117. A. D. 1739.
Rivinia, commun. monog. and chenopodiac, S. tr. W. Ind. which grow freely in light, rich soil, and are readily increased by cuttings or seeds.
Roads, to form, 1905.
Robin, C,—his works on gardening, page 1121. A. D. 1801.
Robinia, diadel. decan. and leguminoseae, S. tr. F. and W. Ind. and H. tr. Siberia, the S. species grow in sandy loam, and are increased by seeds from India, or young cuttings planted in sand under a bell-glass; the H. species grow freely in common soil, and are increased by layers or grafting, or rooting on H. pseudacacia, or from seeds.
Robania pseudacacia, the common acacia, or American locust-tree, 7105.
Robinson,—his works on gardening, page 1112. A. D. 1795.
Robambelle, allium scorodoprasum.
Roche Great Court, Wiltshire, 7596.
Rockhall, A,—his works on gardening, page 1126. A. D. 1832.
Rock rose,—see Cistus.
Rocket,—see Hesperis.
Rocks, as decorations of gardening, 1357; natural rocks, how to operate on, in garden-scenery, 7268.
Rockwork, how to form and plant, 6525.
Rockes, Bartholomew, his new work on gardening, page 1104. A. D. 1753.
Rode,—his works on gardening, page 1128. A.D. 1798.

Rochampton Grove, Surrey, 7597.
Roeiia, pentan. monog. and campanulaceae, a S. tr. peren. and Arch. S. tr. Ind. and Ind. peren. which grow in loam and peat, and are increased by seeds or young cuttings under a hand-glass.
Rolanda, synugen. polyg. extir. and cypoarabegineae, a S. tr. of easy culture: the S. tr. species root in peat, rich soil, and is readily increased by cuttings.
Roller, 1455.
Rolling, 1838.
Rümmer, J. Jacques, his works on gardening, page 1125. A. D. 1791.
Rondeleth, pentan. monog. and rubiaeaceae, G. tr. W. Ind. which grow in loam and peat, and cuttings root in sand under a hand-glass.
Rookery, a seat in Surrey, 7597.
Rook's Nest, a villa in Surrey, 7597.
Root-cellars, 1794.
INDEX.

Ruellia, didyn. angios. and acanthaceae, S. tr. and G. pern. Ind. and Amer. pretty plants of easy culture in light rich soil.

Rulers as objects in garden-scenery, 1859 and 7267.

Rupia, monad. polyan. and malvaccea, a S. tr. and Am. which grows in low and peat, and cuttings thrive in sand under a glass-heat.

Rumex patientia, patience-dock, or spinage-dock, 3267.

Rumex scutatus and acetas, the garden-sorrels, 5799.

Runners, to propagate by, 1911.

Sapippe, duvan, tetrag. and moniec., a H. peren. Brit. a submarine aquatic, which should be grown in sand, kept moist, and occasionally strewed with salt.

Rupture-wort, — see Hernia.

Rushborough, a seat in Wicklow, 7554.

Ruscus, butcher’s broom, dicoc. monad. and siliaceae, a G. and H. tr. Eur. under-shrubs, evergreens, which will grow in shady situations, and are increased by dividing at the root.

Rush, see Juncus.

Rush-broom, viminaria denudata.

Rush-nut, cyperus esculentus, — see Cyperus.

Rushbrook Hall, Suffolk, 7552.

Ruttalton, a seat in Northamptonshire, 7550.

Rusell Square, London, 7320.

Russel, hardly. angios. and scrophularineae, a S. tr. S. Amer. a pretty plant which thrives in light rich soil and cuttings root readily under a hand-glass in heat.

Ruta, rue, decan. monog. and rutaceae, G. and H. and pern. Afr. under-shrubs, evergreens, which prefer light soil and are readily increased by cuttings or seeds.

Rutlandshire, gardens and residences of, 7579.

Ruderat, and Daniel Butler, their works on gardening, page 1107. A.D. 1767.

Rye, — see Secale.

Rye-grass, leucom perenne.

S.

Sabal, hexan. trig. and palmae, a S. peren. Florida, which grows in low sandy loam, and may be occasionally increased by suckers.

Sabb. hort., Sabbati (liberatus) Hortus romanus.

Sabbatia, pentan. monog. and gentianaceae, H. biun. N. Amer. of easy culture.

Sacharum, canar. cane, triuran., digy. and gramineae, a S. peren. Ind. which grows in rich loam, and is increased by suckers or cuttings of the stem.

Sagittaria, agrostis, his work on gardening, page 1128. A.D. 1767.

Sacred bean, — see Nelumbo.

Sage, — see Salvia.

Sagittaria sagittifolia, common arrow-head, 4300.

Sago-palm, sagus rupibus.

Sagus, sagus, monoe. palmae, and palmae, a S. tr. which requires a sandy loam and a strong moist heat.

S. Andrew’s cross, asynum cruc Andreae.

S. Anne’s Hill, a seat in Surrey, 7267.

Saint Etienne, Claude de, a French author on gardening, page 1116. A.D. 1690.

S. John’s Port, — see Hytheport.

S. Laurence’s Cottage, Hampshire, 7594.

S. Mary’s Isle, a seat in Kirkcudbrightshire, 7625.

S. Peter’s wort, symphicta glomerata.

Saint Patrick, see Royer.

Saint Simon, Marquis de, his works on gardening, page 1118. A.D. 1789.

Sainttofin, — see Hedysarum.

Salal, to grow in cellars, 3929.

Salad-plants, — see Aetarious Plants.

Salads of wild plants, 4317.

Salicornia, glasswort, monoe. monog. and chenoideae, a G. tr. Arabia, and a H. tr. peren. and an. Brit. succulent salt-marsh plants, which grow in rich light soil not overwatered.
Sali corridor, saxifrage, saphire, 4282.
Salix, see monoece. poplen, and popocarpacea, a H. tr. Japan, which grows in sheltered situations, in common garden soil, and is increased by layers.
Salisbury Craig, a hill at Edinburgh, how to improve, 1117.
Salisbury, William, his writings on gardening, page 1117. A.D. 1797.
Salix, willow, dioec. monan. and amenacetum, a S. tr. E. Ind. and H. tr. Eur. and N. Amer. which grows mostly in moist soil, and are readily increased by cuttings.
Salix alba, the Huntinton and other tree willows grown for timber, 7144.
Salix viminalis, the common osier, and other basket and hoop willows, 7149.
Sallows, see Salix.
Salix, see Tragopogon.
Salvia, see officinalis, dig. and chenopodceae, a G. tr. S. Eur. and a H. peren. and an. Eur. and Afr. which may be treated like salicornia.
Salt, as a manure, 1189.
Salt-tree, robinia haldendorfi.
Salt-wort, see Salsola.
Salt, J., his work on gardening, page 1114. A.D. 1816.
Salon Hall, a seat in East Lothian, 7619.
Salam, a seat in Devonshire, 7600.
Salvias, see, dian. monog. and labiatea, S. and G. tr. and an. and peren. and an. all of easy culture in light sandy soil.
Salvia officinalis, the common sage, 4140.
Salvia scarceae, clary, 4145.
Salustrua, F. Z., gave the King to the Prussia, 208; his works on gardening, page 1124. A.D. 1781.
Sang., Samouelle's Entomologist's Useful Companion.
Salusbury, ——, his poem on gardens, page 1131. A.D. 1788.
Sambucus, elder, pentan. trig. and caprifolium, H. tr. and a peren. Eur. and Amer. of easy culture, and increase by cuttings or seeds.
Sambucus nigra, the common elder, as a fruit-tree, 4527; as a forest tree.
Sangh, see Crtinium and Inula.
Sannfricq, C. L., his works on gardening, page 1125. A.D. 1788.
Salvia, decan. monog. and homalineae, a S. tr. W. Ind. which grow, though shily, in loam and peat, and cuttings root in sand under a hand-glass.
Sandalwood, santalum album.
Sandbeck (sand-brook), a seat in Yorkshire, 7582.
Sandbox-tree, see Hura.
Sanddon, a seat in Staffordshire, 7570.
Sandwell Park, Staffordshire, 7570.
Sandwort, see Arenaria.
Sang, Edward, his edition of Nicol's Planter's Calendar, page 1112.
Sanginum, parchou, polyan. monog. and papa-veraceae, a H. peren. which grows best in light sandy soil, and increases by seeds, or offsets from the root.
Sangulorbia, great burnet, tetan. monog. and rosacea, H. peren. Brit. and Amer. of common culture.
Sancle, see Sanieula.
Sanicula, sanicule, pentan. dig. and umbellifereae, H. peren. Brit. and Amer. of easy culture.
Sans Socul, a royal palace at Poisdam, 2008.
Sans Souci, hexan. monog. and hem派遣ia, S. peren. and a H. tr. E. Ind. and China, succulents increased by suckers.
Santalum, sandalwood, a tetr. monog. and santalaceae, a S. tr. E. Ind. which grows in light loam, and cuttings root in sand under a hand-glass.
Sapindus, lavender-cotton, syngen. polyg. equal. and corymbifereae, H. tr. and per. Eur. which grow in common garden soil, and are readily increased by cuttings.
Sarantia, syngen. polyg. super. and corymbifereae, a H. an. Mexico, of easy culture.
Sapindus, soapberry, oclan. trig. and sapindaceae, a S. tr. and G. tr. Amer. which thrive well in loam and peat, and large cuttings root in sand under a hand-glass.
Sapium, monoece. monad, and euphorbiaceae, a S. tr. W. Ind. which grows in loam and peat, and cuttings root in sand under a hand-glass.
Saponaria, soapwort, decan. dig. and carpyphyllae, H. peren. Eur. of easy culture.
Sarcophyllum, diadel. decan. and leguminosee, a G. tr. C. B. S. a succulent which grows in loam and peat, not overwatered, and cuttings root readily in sand under a bell-glass.
Sarcostemma, pentan. dig. and asclepiadeae, a S. tr. E. Ind. a climber which grows in loam and peat, and cuttings root in sand under a hand-glass.
Sarracenia, side-saddle flower, polyan. monog. and .........., F. peren. N. Amer. which grow in pots, with turfy peat at the bottom, and the upper part filled with magnolia, in which the plants must be set, and then placed in pans of water in a shady situation.
Sartorelli, G. B., his works on gardening, page 1129. A.D. 1816.
Sassafras-tree, laurus sassafras.
Satureja, savory, didyn. gymnos. and labiatea, a S. tr. G. tr. and H. peren. and an. Eur. and N. Amer. of easy culture.
Satureja montana and hortensis, winter and summer garden savory, 4170.
Saxifraga, brick tail, heptan. tragan. and lanaeae, a H. peren. an aquatic increased by parting at the root.
Sawas, le Sier de, a French writer on gardening, page 1117. A.D. 1729.
Sawassure, Nicolas de, his works on gardening, page 1124. A.D. 1775.
Sawanna-flower, echtes suberecta.
Saw, Gers, his work on gardening, page 1118. A.D. 1811.
Savin, juniperus sabina.
Savory, ——; see Satureja.
Saw, 1531.
Saw-wort, ——; see Serratula.
Sawing, 1853.
Saxifraga, crassifolia, ssauber, and saxifragae, F. and H. peren. and an. Eur. and N. Amer. chiefly alpine, and well adapted for rockwork; but some, as S. nivalis, hierculu, &c. are marsh plants; all are of easy culture.
Saxifraga crassifolia, as a tea-plant, 4519.
Saxifrage, ——; see Saxifraga.
Scarious, ——; see Scabiosa.
Scevolus, pentan. monog. and goodeneae, a S. tr. G. tr. and peren. W. Ind. and Austral. which grow freely in loam and peat, and cuttings root readily under a hand-glass.
Scammony, see Conversewoll scammonia.
Scandix cerefolium, chervil, 4107.
Scandix odoratus, sweet celeriac, 4314.
Scare, for birds and vermin, used in gardening, 1483.
Schabel, Jean Roger, his works on gardening, page 1118. A.D. 1767.
Schaffera, dioec. tetran. and ............, a S. tr. W. Ind. which grows in loam and peat, and may be increased by layers or cuttings in sand under a bell-glass.
Scheucheria, hexan. trig. and alismaceae, a H. peren. Eng. a marsh plant increased by seeds.
Schider, I., his works on gardening, page 1125. A.D. 1705.
Schinus, dioec. decan. and terebintheae, G. tr. and H. tr. S. Amer.—which grow in loam and peat, and ripened cuttings, with their leaves not shorted, will root freely in sand under a hand-glass.
Schisandra, monoece. pentan. and menispermeae, a G. tr. N. Amer. a climber which grows in sandy peat and loam, and ripened cuttings root in sand under a bell-glass.
Schkubri, syngen. polyg. super. and corlymbeae, a H. an. Mexon. of common culture.
Schmeha, C., his works on gardening, page 1125. A.D. 1796.

Schweitzingen, Duke of Baden's gardens at, 214.
Schwenkia, dian. monog. and scrofularinese, a S.
bien. Guinea, of easy culture.
Schwobber, gardens of, in Hanover, 204.
Scilla, squill, hexan. monog. and asphodeleae, a G.
peren. and H. peren. Eur. and C. B. S. bulbs of
easy culture.
Scilla esculenta, the quamash, 4334.
Scions for grafting {scion, Fr.), 2043.
Scirpus, club-rush, triand. monogynia and cyperaceae, a S. peren. E. Ind. and H. peren. Brit, marsh
grasses of easy culture.
Scirpus tuberosus, the water-chestnut, 6032.
Scleranthus, knawel, decan. dig. and portulaceae, a

H. peren. and an. Brit, which grow best in light,
sandy soil, and are easily propagated.
Sclerocarpus, syngen. polygam. frust. and corymbifereae, a G. an. Guinea, of common culture.
Sclerothamnus, decan. monog. and leguminoseae, a
G. tr. of N. Holl. which grows in sandy loam and
peat, and young cuttings root in sand under a
bell-glass.

Scleroxylon, pentandria monogynia and sapoteae, a
G. tr. C. B. S. which grows in loam and peat,
and ripened cuttings root in sand under a hand-

earth in the shade, or in pots.
Scolymus, golden thistle, sygen. polyg. aequal. and
cichoraceae, a F. bien. and H. peren. and an. Eur.
As. and Afr. of easy culture.
Scone Palace, Perthshire, 7636.
Scoparia, tetran. monog. and scrophularineae, a S.
an. Jamaica, of common culture.
Scopolia, pentan. monog. and thymelese, a S. tr. E.
Ind. which grows in loam and peat, and cuttings
root in sand under a hand-glass.
see Myosotis.
Scorpion-grass,
Scorpion-senna, coronilla emerus.
Scorzonera, viper's grass, syngen. polyg. sequal. and
cichoraceae, H. peren. and bien. Eur. of common
culture.
Scorzonera hispanica, the garden viper's grass, 3746.
Scotland, gardens and residences of, 7615.
Scottia, diadel. decand. and leguminoseae, a G. tr.
N. Holl. which thrives in loam and peat, and
young cuttings, taken off at a joint, root in sand

Shrubbery, planting of, 6138: in the mingled manner, select manner, systematic manner, general practice, fruit-trees in shrubberies, decorations, 6133 to 6138.
Shrubbery, the culture and management, 6187: times of planting and sowing, pruning, training, thinning, and dressing, grass plots, protecting, water, insects, 6188 to 6201.
Shrubbery, considered in respect to landscape-gardening, 6092.
Shrubby trefoil, pletea trifoliata.
Shrub, ornamental, wall, skull—see Scelolauria.
Slane Castle, a seat in Eastmeath, 7601.
Slane Castle, a seat in Abbeyfeale, 7639.
Silage, county of, to gardening, 6765.
Silphium, a stripe root of, growing in the ditches, 6242 to 6252.
Slippers, —see Calceolaria.
Slopes, to propagate by, 1893.
Slo. sist.? A passage to the islands of Madeira, Bar.
Slo. Jam. bades, Nevis, St. Christopher's, and Jamaica; with the natural history of the last of these islands. By Hans Sloane.
Sloane Square, London, 7521.
Sloanea, polyan. monog. and tilicææ, a S. tr. S. Amer. which thrives in loam and peat, and cuttings may be rooted in sand under a hand-glass.
Slothorpia, didyn. angios. and scrophulariaceæ, a H. peren. Eng. which grows well in peat and loam, in rockwork or in pots, and is increased by dividing at the root.
Slecker, T. Volkmann, his works on gardening, page 1125. A. D. 1794.
Slycos, single-seeded cucumber, monoc. monad. and cucurbitaceæ, a H. an. Amer. of common culture.
Sida, monad. polyan. and malvaceæ, S. and G. tr. bien. and an. W. Ind. C. B. S. and S. Amer. which flower freely in rich light soil, and are readily increased by seeds, or cuttings will root well in sand under a hand-glass.
Side-saddle flower,—see Sarracenia.
Sideritis, iron-wood, didyn. gymnos. and labiateæ, G. and F. tr. peren. and an. S. Eur. and E. Ind. which grow freely in rich light soil, and are readily increased by cuttings.
Siderodendrum, iron-tree, tetran. monog. and rubiaceæ, a S. tr. W. Ind. which grows in loam and peat, and cuttings root in sand under a hand-glass.
Sideroxylon, iron-wood, pentan. monog. and sapoteæ, a G. tr. C. B. S. which thrive in loam and peat, and cuttings, a little ripened, root in sand under a hand-glass.
Siegel, D. 1802.
Siegesbeckia, syn. polyg. superf. and corymbifereæ, H. an. India and Peru, of common culture.
Siemssen, A. C., his work on gardening, page 1125. A. D. 1797.
Sieve, the garden, 1394.
Silene, catchfly, decan. trig. and Caryophyllaceæ, G. bien. and H. peren. bien. and an. a numerous genus, which thrive in loam soil, suit well for rockwork or pots, and are readily increased by division, seeds, or cuttings.
Silene inflata, the bladder-catchfly, 6392.
Silk cotton tree,—see Bombax.
Silphium, syn. polygam. necess. and corymbifereæ, H. peren. N. Amer. robust, unsightly plants, easily increased.
Silva, Sigismondo, his work on gardening, page 1128. A. D. 1803.
Silver-tree, leucadendron argentsumæ.
Simplex,—see Physic Gardeners.
Snapis, mustard, tetrad. silic. and cruciferæ, a G. tr. and a H. peren. bien. and an. Eur. and E. Ind. of easy culture.
Snapis alba and nigra, white and black mustard, 4020.
Snapis arvensis, field-mustard, 4257.
Snapis Pekinensis, 4325.
Sinclair, Sir John, his writings on gardening, page 1114. A. D. 1813.
Single-seeded cucumber, sicyia angulata.
Sion,—see Scion.
Sion Hill, a seat in Middlesex, 7591.
Sion House, Middlesex, 7522.
Sison, honowert, pentan. dig. and umbellifereæ, H. peren. and a H. Amer. of easy culture.
Sisyrium, tetrad. silic. and cruciferæ, a G. tr. Canaries, and H. peren. bien. and an. Eur. which grow in any soil, but most of them prefer a moist situation: S. renifolium, however, grows on old walls.
Sisyrium officinalis, common water-cress, 4652.
Site (Silus, Lat.), the situation, or ground on which a building, garden, or other object stands.
Sium sibiricum, the skimperweed, 7494.
Skelton Castle, Yorkshire, 7592.
Skibo, a seat in Sutherlandshire, 7546.
Skirret,—see Scion.
Skirret,—see Scelolauria.
Slane Castle, a seat in Eastmeath, 7601.
Slaines Castle, a seat in Abbeyfeale, 7639.
Silo, county of, to gardening, 6765.
Silo, a stripe root of, growing in the ditches, 6242 to 6252.
Silper-wort,—see Calceolaria.
Silps, to propagate by, 1893.
Slo. sist.? A passage to the islands of Madeira, Bar.
Slo. Jam. bades, Nevis, St. Christopher's, and Jamaica; with the natural history of the last of these islands. By Hans Sloane.
Sloane Square, London, 7521.
Sloanea, polyan. monog. and tilicææ, a S. tr. S. Amer. which thrives in loam and peat, and cuttings may be rooted in sand under a hand-glass.
Slopes, a shooting party at Windsor, 6159.

Smyth, — see Limax.

Stoenus, their form and situation, 1531.

Small salads, 4076; to force, 4302.

Smith, hexam. monog. and simileace, H. peren North America, which succeed best in light sandy soil, and are increased by dividing the root.

Smith, dicere, hexam. and simileace, G. and F. tr. and peren. which grow freely in loam and peat on rich light soil, and are increased by dividing at the root, and the woody kinds also by cuttings.

Snow, diadel. decent and leguminosae, a S. an. E. Ind. of easy culture.

Snit, — see Ustilago.

Snow, fungi, alexanders, pentan dig. and umbelfe-
re, H. peren. and a bien. Eur. and N. Amer. of easy culture.

Smyrnium olusatrum, the garden alexanders or alliace, 9494.

Snaill, — see Helix.

Snake’s beard, phylopogon japonicus.

Snake’s tongue, lysodium scandens.

Snakewood, cercopis peltata.

Snap-dragon, antirrhinum majus.

Snap-tree, justicia hispinofolia.

Snowberry, white or purple flower.

Snow, its formation, 1554; heat from, &c. 1907.

Snow, T., his works on gardening, page 1105. A.D. 1715.

Snowberry, chioscoca racemosa.

Snow-drop, galanthus nivalis.

Snow-flake, — see Leucojum.

Soapberry, — see Sapopamia.

Society of Gardeners, their work on gardening, page 1165. A.D. 1750.

Society of Practical Gardeners, their work on gar-
dening, page 1192. A.D. 1802.

Sod, a turf, or thin layer of earth, covered with grass, taken from a lawn or pasture with a spade.

Sodcrini, G. and Bernardo Davazzati, their work on gardening, page 1128. A.D. 1622.

Sodercini, S., his works on gardening, page 1128. A.D. 1811.

Sorrel, the, — see Holcus.

Sorrel, wood-nymph, 7125.

Sorrel, mixed soils, 932; aquatic soils, 932; earthy soils, 930; vegetable soils, 938.

Sorrel, as indicated by spontaneous vegetables growing in fresh cuttings, 1031; of plants indicating the more common soils, 1037.

Sorrel, improvement of, 1068; by pulverisation, aeration, alteration, removal of superfluous ingredients, incinera-
tion changing the condition of lands as to water, draining, embanking, subterraneous irrigation, surface irrigation, changing the condition of lands in respect to atmospheric in-
fluence, solar influence, shelter, rotation of crops, Sir H. Davy’s opinion on rotations, Grien-
swhteave’s opinion, 1069. to 1110.

Soils, table of, their nomenclature and classification, 1094; discovering their qualities, 1033; uses of soil to vegetables, 1051.

Solandra, pentan. monog. and solaneace, S. tr. Ja-
maica, free-growing plants, which, when it is in-
tended they should flower, must be put in a state of rest by withholding water till their leaves drop. The plants are very easily rooted asexually.

Solana, nightshade, pentan. monog. and solane-
aceae; G. and S. tr. peren. and an. and H. peren. and an. all of easy culture in rich light soil.

Solana, lycopersicum, the love-apple, 4599.

Solana, melongena, the egg-plant, 4566.

Solana, tuberosum, the potatoe, 3044; to force the peren. 3581.

Soldanella, pentan. monog. and primulaceae, H. peren. Germ. alpines, pretty little plants, which grow well in rockwork or in pots, in two or three sandy loams; they are increased by parting the root.

Soldier-wood, inga purpurea.

Sonchus, golden rod, argirodesia polygonia super-
flua and corymbiferus, H. peren. N. Amer. and Eur. large cushionsome plants of the easiest cul-
ture.

Solomon’s seal, — see Phomanoma.

Somerfeldt, Christian, his work on gardening, page 1150. A.D. 1785.

Somesethire, gardens and residences of, 7599.

Somolus, brook-weed, pentan. monog. and primula-
ceae, G. tr. peren. N. S. W. and H. peren. Brit. The first grows in loam and peat, and cuttings root under glass; the other prefers a moist situation, and is increased by dividing at the root.

Sonchus, corydicus, syngen. polyg. aquil. and el-
chreanthera, G. tr. and H. peren. Madeira, N. Amer. and Eur. of easy culture.

Sonchus oleraceus, the common sow-thistle, 4299.

Somnun, — see P. S. S., his works on gardening, page 1121. A.D. 1894.

Sophiowski, a fine seat in Podolia, now much ne-
glected, 504.

Sophora, pentan. monog. and leguminosae, a S. tr. India, H. tr. Japan, and H. peren. Eur.; the tender species thrive well in light loam, and cut-
tings may be raised and set under a hand-glass; the hardy herbs require a rich loam, and are increased by seeds or dividing at the root.

Sorghum, polyg. monoc. and gramineae, a S. bien. and H. peren. and an. As. and Eur. of easy cul-
ture.

Sorocephalus, tetran. monog. and proteaceae, G. tr. C. B. S. which require to be treated as protea.

Sorrel, — see Rumex.

Sour gourd, adansonia digitata.

South America, fruits deserving cultivation, 6500.

South Lodge, Middlesex, 7525.

South Sea tea, ilex vomitoria.

Southam House, Gloucestershire, 1565.

Southernwood, artemisia abrotanum.

Southgate Grove, Middlesex, 7580.

Sow-thistle, — see Sonchus.

Sowthistle, pentan. monog. and asphodeleen, G. peren. N. S. W. which thrives in peat soil with plenty of water, and is increased by dividing at the root.

Sowerby, James, F. L. S., his works on gardening, page 1110. A.D. 1789.

Sowing, different modes of performing the opera-
tion, 2641.

Spade, Roman (lígo), Italian (sappa), French (beche), and Chinese, 31.

Spade, spí or spitter (spada, Lat. and Sax. spade, Dan.), an implement for penetrating and breaking up the soil, different kinds of, 1300.

Spananthe, pentan. dig. and umbelfeere, a S. bien. Caraccas, of easy culture.

Spanish elm, cordia gerasanthus.

Spanish nut, mora sisyrinchium.

Sparaxis, triand. monogyn. and irideae, G. peren. C. B. S. bulbs which require the same treatment as ixia.

Spardoni, Paulo, his work on gardening, page 1128. A.D. 1812.

Sparrmannia, polyan. and toldiceae, a G. tr. C. B. S. grows in sand and peat, and cut-
tings root readily under a hand-glass.

Sparrow-wort, — see Passerina.

Sparrow-berry, diadel. decent. and leguminosae, G. and H. tr. Europe and Africa, which thrive in loam and peat, and are readily increased by seeds, or by young cuttings in sand under a bell-glass.

Spatalla, tetran. monog. and proteaceae, G. tr. C. B. S. which require the same treatment as protea.

Squalia, pentan. trig. and terebinaceae, a S. tr. Jamaica, which thrives in light loam, and cut-
tings root readily under a hand-glass.

Spreckley, William, his works on gardening, page 1108. A.D. 1779.

Speedwell, — see Veronica.

Spergula, spanyren, decem. pentag. and caryophyllaceae, H. peren. and an. of easy culture in soft moist soil.

Spermacoce, button-weed, tetran. monog. and ru-
hicaceae, H. peren. and an. Brit. As. and C. B. S. which grow freely in loam and peat, and are in-
creased by cuttings under a hand-glass, or by seeds.

Sphacelanthus, syngen. polyg. segreg. and cynaroco-
phaceae, a S. peren. É. Ind. and G. an. C. B. S. of easy culture.

Sphacelochiton, decem. monog. and leguminosae, G. tr. N. Holl. pretty plants, which grow in sandy loam and peat, and young cuttings root readily in sand under a bell-glass.
Sphenogyne, syngon. polyg. frut. and corymbifl., G. tr. and a H. an. C. B. S. which thrives well in light rich soil, and cuttings root readily under a hand-glass, root freely.
Sphinx elpenor, the elephant hawk-moth, 6193.
Spiderwort, — see Tradescantia.
Spinacia, didyn. angios. and verbenaeeae, a G. tr. C. B. S. which may be treated as sphenogyne.
Spinellia, worm-grass, pentan. monog. and gentianaeae, a S. an. W. Ind. and H. peren. Amer. which are best grown in sandy loam and peat, and are readily in- creased by cuttings.
Spinellia, — see Athamanta.
Spike-rush, — see Eleocharis.
Spinacea palustris, Valeriana satamansi. V. celtica and officinalis may be used as substitutes by those who prefer this sort of perfume.
Spiranthes, syngon. monog. and corymbifl., a S. peren. C. B. S. which grows in rich light soil, and cuttings root readily under a hand-glass.
Spatula, — see Athamanta.

Stock, — see Mathiola.

Stokesia: polyg. segreg. and corymbiferae, G. tr. C. B. S. which may be treated as stizolium.

Stoke; a seat in Herefordshire, 7568.

Stoke-hole, the excavation in one side of which hot-house furnaces are often built, and the hole contains fuel for its supply.

Stone House, Gloucestershire, 7565.

Stoke Park, Buckinghamshire, 7547.

Stoke Park, Wiltshire, 7597.

Stokefield, Yorkshire, 7597.

Stokesia, syngen. polyg. equal. and corynacophala, a G. peren. Carolin. a pretty plant which grows in rich, light soil, and roots freely under a hand- glass.

Stoke-town, a seat in the county of Roscommon, 7530.

Stolton, from stol, Lat. a shoot or twig, trees which, when cut over by the surface, shoot up again.

Stone-crop, — see Sedum

Stone-fruit, catalogue of, 4480.

Stoneham Park, Hampshire, 7594.

Stones, how to operate with in gardening-scenery, 7230.

Storax, — see Styrax.

Storr's hill, — see Pelargonium.

Stornberg, his plan of a Chinese garden, 478.

Stourhead, a seat in Wiltshire, 7597.

Stout Hall, Glamorganshire, 7598.

Stout's Hill, Gloucestershire, 7565.

Stove, dry, — see Dry-stove.

Stove-plants, or bark-stove, — see Bark-stove.

Stove-plant, — see Bark-stove and Dry-stove.

Stowe, a seat in Buckinghamshire, 7548.

Stowels, a seat in Gloucestershire, 7565.

Strange Hall, in Queen's County, 7609.

Stradmore, or bennet cranberry, 7283.

Strawberry, — see Fragaria.

Strawberry, trit., see Rubus.

Strawberry-bite, — see Blitum.

Strawberry Hill, Middlesex, 7590.

Strawberry-tree, — see Arbutus.

Stream of water, how to improve in garden-scenery, 7235.

Strathearn, Surrey, 7297.

Street-gardens, 7596; their management, 7496.

Strelitzia, peand. monogyn., and musaceæ, S. tr. C. B. S. which grow in sandy loam, and are increased slowly by suckers. By rubbing the pollen on the stigma, the plants are in bloom, perfect seeds are readily obtained. (Sweat.)

Streptopus, hexan. monogyn. and sinuaceæ, H. peren. Hung. and N. Amer. with succulent best in light, sandy soil, and are increased by dividing at the root.

Structures, in gardening, 1393; portable or moveable structures, canvas screen, canvas curtain, oiled paper frame netting screen, common glass case, glass tent, common hot-bed frame, separating frame, moveable bottomed frame, Mallet's frame, &c, 1524, to 1538.

Structures, partly moveable, 1399; earth-pit, bark-pit, flued pit, M'Palt's pit, A. d'Leon's pit; pit with rising frame, pits in, 1540, to 1544.

Structures, fixed, 1355; garden walls, brick, stone, or mud walls, solid brick wall, flued wall, cellular wall, mud wall, earth walls, soil wall, wall, wavy wall, gular wall, zigzag wall, square pier wall, nurseryman's wall, pier wall, sheltering pier, arched or roofed walls, espalier rails, wooden espaliers, framed wooden espalier rail, cast-iron espalier rail, horizontal espalier rail, oblone espalier rail, 1536. to 1585.

Structures, permanent, 1853; hot-house, accumulated semi-globe, accumulated semi-dome, semi- ellipse, parallelogram with curved roof and ends, with ridge and furrow roof, polyprosopic hot-house, mushroom-houses, sleeve mushroom-houses, German mushroom-house, cold-houses, 1554. to 1657.

Structures, their further improvement, 1850.

Sumach, hexan. monogyn. and amaryllidææ, G. peren. C. R. S. bulbs which thrive in sandy loam and decayed leaves, require little water when not in a growing state, and are increased by offsets or seeds.

Struthiola, tetrandria monogynia and thyme- lea, G. tr. C. B. S. which grow in sandy peat, and young cuttings root freely in sand under a bell-glass.

Strycnos, pentand. monogyn. and apocynaceæ, S. tr. E. Ind. which grow in sand and peat, and cuttings root in sand under a bell-glass.

Stuartia, polyg. sect. tillicaeæ, H. tr. Amer. handsome plants which thrive in peat soil or very sandy loam; they flower after attaining a good size, and are increased by layers in peat.

Sub House, Durham, 7384.

Studley Royal, Yorkshire, 7582.

Suez, Egypt, 7592.

Stylium, gynan. dian. and styleideæ, a G. tr. and peren. Austral. which grow in sandy loam and peat, of increased by seeds or parting at the root: the shrubby species by cuttings under a hand-glass.

Styphelium, pentand. monogyn. and epcideææ, G. tr. N. S. W. beautiful plants which grow in sandy loam and peat, and young cuttings root in sand under a bell-glass.

Styrax, stratox, hexan. monogyn. and ephedraceææ, H. tr. Italy and N. Amer. which thrive and flower freely in light sandy loam, and are increased by layers or seeds.

Suburban villa, 7285; suburban house, 7286; their improvements, 1543, to 1544.

Sugar-cane, repellant (from succeda, Lat. to cut down, and repululata, Lat. to bud or sprout), trees which stoil, or which being cut over spring again.

Sucrey, see Churum.

Succovia, tetrasilic. and crucifereæ, H. an. Nicora, of common culture.

Suckers to plant by, 1539.

Sudborne Hall, Suffolk, 7592.

Suffocation, see Eruca.

Sugar-cane, increased, 7568.

Suffolk, gardens and residences of, 7529.

Sultan Court, Herefordshire, 7568.

Sugar-cane, - see Saccharum.

Suir Castle, a seat in Tipperary, 7607.

Sulphur-wort, — see Peucedanum.

Sultan's garden at Constantinopile, 508. 1108.

Summer Hill, a seat in Kent, 7538.

Sun-dew, see Drosera.

Sun-dials, as garden-decorations, 1834.

Sun-fern, polypodium phegotepis.

Sun-flower, — see Helianthus.

Sun-rue, — see Helianthus.

Supple-jack, phegopteris.

Surrey, gardens and residences of, 7294.

Sutherland, Buckinghamshire, to 7592.

Sussex, gardens and residences of, 7509.

Sutherlandia, diacl. delcan. and leguminoseææ, C. B. S. which thrives in loam and peat, and is readily increased by seeds.

Sutherland, gardens of, 7466.

Swallow-wort, — see Asclepias.

Sweet flag, acorus calamus.

Sweet gale, myrica gale.

Sweet gum tree, Liquidamar striatcula.

Sweet herbs, 4131.

Sweet pea, lathyrus odoratus.

Sweet peas, 1108.

Sweria, felwort, pentan. dig. and gentianaceææ, H. peren. Eng. a marsh plant which prefers a peat soil.

Swietenia, mahogany-tree, decan. monogyn. and me- laceææ, S. tr. W. and E. Ind. which grow in loam and peat, and rip cuttings, with their leaves not shortened, root freely in sand under a hand-glass in moist heat.

Swinden, N., his work on gardening, page 1108. A. D. 1778.

Swine's meucory, see Hypoëris.

Swings as garden decorations, 1831.

Switzer, Stephen, his works on gardening, page 1102. 1774.

Symphoria, St. Peter's wort, pentan. monogyn. and ca- pilarifolium, a H. tr. N. Amer. a dwarf shrub which grows in the shade of other trees in any soil, and is increased by cuttings in the open ground.

Symphytum, comfrey, pentan. monogyn. and boraginaceææ, H. peren. Edit. of easy culture.
Syndrela, syngenesis polygamia superflua and corymbiferae, a S. an. W. Ind. of common culture, 1749.

Syrian rue, peganum harmala.

Syringa, Iliac, dian., monog. and oleincra, H. tr. Persia and China, of easy culture.

Syringa, common, see Philadelphia.

Syringe, garden, different sorts of, 1418.

T.

Tabern., lceons plantator (eaden ac in tabernamentanei Krauterbuch).

Tabernanthes, pentan., dig. and aceplacea, S. tr. W. and S. Ind. of loam and peat, and cuttings root in sand under a hand-glass.

Tacca, hexan., monog. and aroidice, S. peren. E. Ind. which grow in loam and peat, and are increased by suckers.

Tazacacham, populus balsamifera.

Tagetes, syngen., polyg., supr., and corymbiferae, a G. peren. and H. an. S. Amer. of easy culture.

Tallie d'ete, summer pruning, 2138.

Tallari, vegetables or crops, see Gathering.

Taliaris, a seat in Caermarthenshire, 7614.

Talinum, docec., monog. and portulacaceae, S. tr. and bien. W. Ind. and S. Amer. of a succulent nature, which grow in light sandy loam, and cuttings root freely.

Tallies, or numbering instruments, different kinds of, 1577.

Tallow-tree, stillingia sibifera.

Tamarind, see Tamarindus.

Tamarindus, tamarind-tree, monadelph. tr. and leguminosae, a S. tr. W. Ind. which grows in loam and peat, and cuttings root under a bell-glass in sand.

Tamarisk, see Tamarix.

Tamarix, ornamental, tr. and portulacaceae, a S. tr. E. Ind. and H. tr. Eur. of easy culture, and increased by cuttings.

Tamus, black briony, dicot. hexan. and smilacaceae, a G. tr. Cor., S. and H. peren. Eur. The G. species T. elephantipes, or elephant’s foot, is a curious plant which thrives in light, rich soil, not overwatered when the plant is in a dormant state. Great recommendation is made of conservatories, the plants being taken off at a joint, and planted in pots of sand in bottom heat under a hand-glass. (Bot. Cult. 202.)

The H. sorts are of easy culture.

Tunica covalens, the common black briony, 4285.

Tan, see Bark for the use of tanners.

Tun-y-Bwlch, a seat in Merionethshire, 7614.

Tannacetum vulgare, the common tansy, 1517.

Tee, see Tannacetum.

Tarchonanthus, African fleabane, syngen. polyg. aequal., and corymbiferae, a G. tr. C. B. S. of easy culture.

Tea, see Ervum.

Tea, A., his works on gardening, page 1120. A. D. 18—.

Tattton Park, Cheshire, 7591.

Tawdria, gardens of, 259.

Tavistock, a seat in Devonshire, 7600.

Taxus, yew-tree, dicot. monad. and confereae, a G. tr. China, and G. tr. B. S. and H. peren. Eur. The G. species T. chinensis, or Chinese yew, is a very fine tree, and thrives exceedingly well in loam and peat, and are increased by cuttings root freely in sand under a hand-glass.

Teedia, didyn. angios. and scrophulariaceae, G. bien. Eur. or S. Amer. of easy culture.

Teesdale, tetrad, silic. and cruciferacea, a H. an. Brit. of common culture.

Telipolium, orange, pentan., tr. and portulacaceae, a H. peren. S. Eur. well adapted for rockwork, and easily increased.

Telocep, waratah, tr. monog. and proteaceae, a G. tr. N. S. W. one of the most beautiful of green-house plants, which grows in equal parts of loam, peat, and sand, well drained, not over-watered, and is at its best in an airy situation; ripened cuttings, taken off at a joint, just before growth commences, root in sand under a bell-glass, but not plunged in best.

Temple, Sir William, his works on gardening, page 1101. A. D. 1685.

Temple Grove, formerly Sheen Grove, near East Sheen, Surrey, the seat of Sir William Temple’s horticultural operations referred to by Evelyn and himself. The house is now a boardingschool, 1686.

Templemore, a seat in Tipperary, 7607.

Temples, 1812.

Templetonia, diadel. decan. and leguminosae, a G. tr. N. Holl. which grows in sandy loam and peat, and young cuttings root freely under a bell-glass in sand.

Temporary country-residence, 7821.

Tenthredinicideae, a natural order of insects, comprizing chidly the Linnsean genus tenthrered, or saw-dy.

Tephrosia, diadel. decan. and leguminosae, S. and G. tr. peren. and bien. C. B. S. and Amer. which thrives in loam and peat, and are increased by cuttings in sand under a bell-glass.

Terebinhinate trees, such as have a resinous, or turpentine odor.

Terebration, or blade of grafting, 2038.

Terebinthus pinorium, the noctua pinastri, L. a moth whose caterpillar feeds on the leading shoot of the common pine, and often leaves that tree without a leader, 7044. and 990.

Terminalia, polyg. monosc. and combretaceae, S. tr. E. Ind. which grow in sandy loam, and ripened cuttings, not defoliated, root in sand under a bell-glass.

Terraces, 7566.

Tessier, A. H., his works on gardening, page 1120. A. D. 1791.

Tetragonia, io. di-pentag. and ficoidea, G. tr. peren. bien. and an. C. B. S. and Austral, some-what succulent, which prefer sandy soil, and root readily by cuttings.

Tetragonia expansa, New Zealand spinage, 7594.

Tetragonothea, syngen. polyg. superflue, and corymbiferae, a H. peren. Virgin. which grows in light, rich soil, is increased by dividing at the root, or by seed.

Tetratheca, octan. monogyn. and tremandreae, a G. tr. N. S. W. very pretty plant, which thrives in loam and peat, and cuttings root in sand under a bell-glass.

Tetseady Park, Cornwall, 7601.

Tetruncium gramineum, digit. gymnos. and labiateae, G. F. and H. tr. and H. peren. and an. Eur. and Amer. of easy culture in almost any soil.

Thalia, monan. monogyn. and connexae, a G. peren. S. Carolia, an aquatic, rather hardly, and increased by dividing at the root.

Thalictrum, meadow-rue, polyan. polyg. and ranunculaceae, H. peren. and S. Amer. some of which are adapted for rockwork, or growing in pots, and all are of easy culture.

Thame Park, Oxfordshire, 7588.

Thapsia, deadly carrot, pentan. dig. and umbel lifereae, H. peren. Eur. of easy culture.

Thelygonum, monosc. polyan. and urticaeae, a H. an. S. Eur. of easy culture.

Thelmitra, iron pond, pinnatula. and orchideaee, a G. peren. N. S. W. which grows in sandy loam and peat, and requires little water when not in a growing state.

Theobalbis, a seat in Hertfordshire, 7544.

Thecorhona, chocolate-nut, polyan. decan. and mal- vaceae, S. tr. S. Amer. which grows in light, rich soil, and cuttings root in sand under a hand-glass.

Thermometer, different sorts of, for gardens, 1488, 1498, and 1490.

Thermopsis, diadel. monog. and leguminosae, a H. peren. Siberia, a pretty plant, rather difficult of culture; it grows best in light loam, and is increased by seed.

Thebus, a seat in toad-flax, pentan. monog. and santallocaeae, a G. tr. and H. peren. Eur. Amer. and C. B. S. of which the H. species grow best in chalky soil, and are increased by seeds, and the G. tr. is of common culture in light loam.

Thevus, Theodore, his works on gardening, page 1125. A. D. 1695.
Thier-garten, (wild beast garden) at Berlin, 208.

Thierrot, — his works on gardening, page 1118. A. D. 1769.

Thistle, — see Carduus.

Thlaspi, shepherd's purse, tetrad. silic. and cruci-flora, a H. peren. and of easy culture.

Thompson, John, his work on gardening, page 1105. A. D. 1757.

Thoresby Park, Nottinghamshire, 7516.

Thorn-apple, — see Rubus.

Thornbury Castle, in Gloucestershire, 399.

Thornhill, Essex, 7542.

Thorn Grove, a seat in Worcestershire, 7566.

Thory, Claude Antoine, his works on gardening, page 1192. A. D. 1819.

Thouin, André le Chevalier de, his works on garden- ing, page 1147. A. D. 1757.

Thouin, Mons. Gabriel, his works on gardening, page 1192. A. D. 1819.

Thomson, M. Jean, his works on gardening, page 1152. A. D. 1816.

Throckmorton, Sir Charles Peter, M. D. his works on gardening, page 1130. A. D. 1799.

Thunbergia, dicyan. angios. and acanthaceae, a S. tr. E. Ind., a pretty climbing plant, in flower the greater part of the year, which grows in low soil and peat, and young cuttings root readily under a hand-glass.

Thurso Castle, a seat in Caithness, 7644.

Thyme, — see Thymus.

Thymus, thyme, dicyan. gymnosperm. and labiatea, G. F. and H. tr. Eur. very low shrubs, all of easy culture in dry soil, and increased by cuttings or seeds.

Thymus vulgaris, the common thyme, 4102.

Thorntree, &c. a hemicycl. and asphodelaceae, a G. peren. N. S. W. which grows in low soil and peat, and is increased by dividing at the roots.

Tiarre, decan. dig. and saxifragaceae, a P. peren. and H. peren. N. Amer. which grow in light soil, rockwork or small pots, and are increased by dividing at the root.

Tiecke, — see Conopomum.

Tiger-flower, — see Tigridea.

Tigridia, tiger-flower, monad. trian. and irideae, a H. peren. Mex. a splendid plant which thrives in common soil, but the bulbs must be taken up as soon as they have done flowering, kept dry and free from frost during winter, and planted again in the following spring.

Tiken Hall, a seat in Worcestershire, 7506.

Tilbury Hill, a seat in Surrey, 7527.

Tille-root, — see Geissorhiza.

Tilia, Balsam. monog. and tiaceae, H. tr. Eur. and N. Amer. which grow in any soil, and are increased by layers.

Tiliaceae, a family of species tree-lee, 7128.

Tilia, Tilia, hemicycl. and monog. and tiaceae, H. tr. Eur. and W. Ind. of which some species are parasitical, and may be treated as acridies, the others may be treated like the pine-apple or pit-calamia.

Tillboide, a seat in Clackmannanshire, 7533.

Tiltware, different kinds and qualities of, 6770.

Timber-measurer, 1364; Montefelti's 6770.

Timperary, gardens of, 7667.

Tiptop, the crane-fly, a genus of dipterous insects, 1529; T. oleracea, 4873.

Toad-flax, — see Linaria.

Tobacco, — see Nicotiana.

Toel, George, his work on gardening, page 1114. A. D. 1812.

Toddington House, Gloucestershire, 7565.

Tofeldia, hexan. trig. and melanthaceae, H. peren. Brit. and N. Amer. which do best in a peat soil in a moist situation, and are increased by dividing the root.

Tollagh Palace, in the county of Dublin, 7653.

Tolpis, syngen. polyc. equal. and cichoraceae, a H. tr. France, of easy culture.

Tonquin bean, dip terix odorata.

Toulon, — see Toulon.

Touch me not, imputatios nolantere.

Toulon, botanic garden of, 153.

Tourretia, didyn. angios. and bignoniaceae, a S. au. Peru, of common culture.

Tournefortia, pentan. monog. and boraginaceae, S. and G. tr. and a H. peren. which grow in rich, light soil, and cuttings root freely in sand under a hand-glass.

Touchau de Linseny, Charles Francois, his work on plantations, page 1118. A. D. 1789.

Tower-mustard, 1757.

Tower, Mr. — see Turris.

Tower, 1706.

Towney Hall, Lancashire, 7588.

Tractéc, October Targioni, M. D., his work on gardening, page 1128. A. D. 1777.

Tozzetti, trian. dig. and gramineae, a H. an. of common culture.

Trachelium, throatwort, pentan. monog. and campanulaceae, a G. tr. and H. bien. France and Brit. of common culture.

Trichocarpus, his writings on gardening, page 1109. A. D. 1656.

Tradesman-gardener, 7588.

Tradesman's villa, 7583; their management, 7494.

Tragia, monoc. tetran. and euforbiaceae, a S. peren. and an. and H. an. W. Ind. and H. peren. and S. Amer. all of easy culture in light, rich soil.

Tradesman-gardener, 7588.

Tradescantia, — see Conopomum.

Tree-celandine, — see Tournesol.

Tree-transplanter, 7547.

Tree-planting, 2140.

Trees, and their uses in different sorts of, used in gardening, 1435 and 1473.

Tree-saw, a seat in Westmeath, 7662.

Travelling gardener, 7385.

Trachelium, — see Tradescantia.

Trachilium, — see Tradescantia.

Tragopogon porrifolius, the salby, 5750.

Treasing trees and plants, different methods of, 5140.

Transplanter, for herbaceous plants, 1369.

Transplanting, different methods of performing,

Trapa, water-calitrops, tetran. monog. and hydrocharideae, a G. peren. and H. an. aquaticis of easy culture, 6537.

Trapa natans and bicornis, 6537.

Traps for vermin, different sorts of, used in gardening, 1435 and 1473.

Tresternough, a seat in Westmeath, 7662.

Trellis, — see Rowel.

Tree-mallow, lavatera arborea.

Tree-surveyor, 7461.

Tree, — see Rowel.

Trees, their uses individually, 6744; in civil architecture, military architecture, naval architecture, construction of machines, implements, utensils, fuel, tanning, dying, various uses, food, medicine, poison, 6745 to 6760.

Trees, classification of, according to their uses, 6760; for timber, building, charcoal, ashes, pales and fencing, hoops, &c. shelter, shade, improving bad soil, separation and defence, exclusion, &c., 6760 to 6769.

Trees, their uses in ornamental scenery, 6785; form, mode of growth, duration, and expression, 6756 to 6801.

Trees, their wounds, bruises, casualties, and defects, 6925.

Trees, insects and vermin by which they are infected, 6926.

Trees, their products, 6935; pruning, thinnings,
U.

Udun salictum (aulus, a, um), wet or moist, and saliva, i, a widow-ground), a proper situation for growing willows.

Ulex, liruce, diadel. deean. and leguminosaes, H. tr. Brit. which grow best in dry soil, and are increased by seeds.

Ulmus, elm-tree, pentan. dig. and amantaceae, H. tr. Brit. and N. Amer. and a G. tr. China, all of which thrive in loamy soil, and the G. is increased by cuttings under a hand-glass.

Umbrella-wort, Valiantia, Upsal, Underley Ulex, a carnation-saucer, sphagnum pump, glass, W. Eur. peren. thrives herb, and is increased for growing by dividing and outgrowths, in the next day, 548, to 554.

Vegetable kingdom, origin and progress of the study of, 547; among the ancients, in modern times, in the present day, 548, to 554.

Vegetable glossology, or the names of the parts of plants, 556.

Vegetable photography, or the nomenclature and description of plants, 557; vulgar mode of naming plants, scientific rules for names, names of classes and orders, names of general classes, of varieties and subvarieties, description of plants, herbariums, methods of study, &c. 558, to 582.

Vendler, G. tr. Brit. and amantaceae, H. tr. the common stinging nettle as a potherb, and to force, 4362.

Vegetables, a small fungus, which is thought to occasion the gout and smut, 878.

Utena, sp. 580; mould with an open sieve, mould-scuttle, mould-basked, flower-pot, store-pot, pot for bulbous roots, classic pot, stone-ware pot, glazed pot, flowerpot-gauge, square pot, saucer, carnation-saucer, propagation-pot, blanching-pot, plant-box, plant-basket, planter's basket, watering-pot, watering-tube, garden-yringe, hand-forcing-glass, portable canuous or grass case, oil-paper shade, straw-net, garden-net, horizontal shelter, plant-umbrella, earthenware shelter, leaden hand-glass, cast-iron hand-glass, wrought-iron hand-glass, green bell-glass, crystal bell or receiver, utensils for entrapping vermin, the common snail, 14378.

Utensil, as expressive of design in landscape-garden, 7109.

Utricularia, hooded milfoil, dian. monog. and len-tilaceae, H. peren. Brit. marsh plants, which prefer peat soil, or they will grow in pots of sphagnum with a little peat earth at bottom, set in pans of water.

Uvularia, sp. polyg. and annemoseae, S. E. and W. Ind. which thrive best in sandy loam, and ripened cuttings root in sand under a hand-glass in heat.

Uvulária, hexan. monog. and melanthaceae, H. peren. N. Amer. which grow in light sandy soil, and are increased by dividing at the root.

Valerian, valerian, trian. monog. and dicaceae, H. peren. and an. Eur. of easy culture; the smaller sorts grow best in light soil, and answer well for pots or rockwork.

Van Houtstia, or lambs-lettuce, — see Fedia.

Van Winkle, a seat in Fifeshire, 7855.

Van Dieman's Land, gardening of, 504.

Van Kameren's list, their works on gardening, page 1129. A. D. 1768.

Van Sterbeck, Francis, his works on gardening, page 1129. A. D. 1682.

Vanes as decorations, 1835.

Vanguardia, sp. monog. and rubiaeae, a S. tr. Ind. which grows in sandy loam and peat, and cuttings root freely in sand in heat under a hand-glass.

Vanilla, gynan. monoch. and orchideaes, S. tr. trailers and parasitic which root at every joint, and in the bark of the trees, on which they grow. They may be treated as aëries, and are readily increased by cuttings.

Various British authors, who have touched incidentally on gardening, page 1105. A. D. 1760.

Vegetable kingdom, origin and progress of the study of, 547; among the ancients, in modern times, in the present day, 548, to 554.

Vegetable glossology, or the names of the parts of plants, 556.

Vegetable photography, or the nomenclature and description of plants, 557; vulgar mode of naming plants, scientific rules for names, names of classes and orders, names of general classes, of varieties and subvarieties, description of plants, herbariums, methods of study, &c. 558, to 582.

Vegetable glossology, or the names of the parts of plants, 556.

Vegetable photography, or the nomenclature and description of plants, 557; vulgar mode of naming plants, scientific rules for names, names of classes and orders, names of general classes, of varieties and subvarieties, description of plants, herbariums, methods of study, &c. 558, to 582.

Vegetable organology, or the external structure of plants, 500. Perfect plants: their conservative organs — root, trunk, branches, leaf, food; conservative appendages — germs, plants, tendrils, stipula, petiol, lamina, arachis, anther, operculum, anther-scales, male-structures; reproductive organs — flower, flower-stalk, receptacle, inflorescence, fruit; reproductive appendages; appendages proper to the flower of the fruit. Imperfect plants: filices, equisitateae, and lycopodineae — conservative organs, reproductive organs; mucii — conservative organs, reproductive organs; hepaticae — conservative organs, reproductive organs; algae and lichens — conservative organs, reproductive organs, utility of the algae fungi — conservative organs, reproductive organs, reproductive uses of the fungi, 501, to 604.

Vegetable anatomy, or the internal structure of plants, 603. Decomposite organs — seed, nucleus, pericarp, exocarp, mesocarp, stach, leaf, fibre, leaf-stalk, leaf-blade, layer, lamina, lenticule, lenticel, appendages, epicarp, mesocarp, endocarp, propogus, gongylus, caudex, appendages; composite organs — epidermis, pulp, pith, cortical layers, ligneous layers, concentric layers, concentric layers; elementary or vascular organs — utricles, tubes, large tubes, small tubules, apertures, pores, gaps, appendages, 606, to 632.

Vegetable chemistry, or primary principles of plants, 635. Mechanical processes; chemical processes; compound products — gum, sugar, starch, gluten, albumen, quinina, extracbe, of quinone, of quinquinum, of safron, colorating matter, tan- nins, bitter principle, narcotic principle, oxalic acid, citric acid, malic acid, gallic acid, tartaric acid, benzoic acid, prussic acid, fixed oils, volatile oils, wax, butter of cacao, of coca, of nutmeg, tallow of croton, wax of myrtle, resin, rosin, gum, bloom, gum-resins, balsams, cam- phor, catouche, cork, wool, resin, charcoal, sap, proper juice, ashes, alkales, earths, silicone, magnesia, metallic oxides; simple products, 635, to 714.

Vegetable physiology, or the functions of plants, 715. Germination of the seed, physical phenomena, chemical phenomena, food of the plants, and the trans- planting plant — water, gases, carbonic acid gas, oxygen, nitrogen, hydrogen, extracts, salts, earths, manures; process of nutrition — intrasus- ception, conception, absorption of the sap; the ascent, elaboration of the sap, of carbonic acid, of oxygen, decomposition of water, descent of the proper juice, causes of descent; process of vegetal development; elementary organs — compo-
Vegetables, to form new varieties of, 1013.
Vegetables, to preserve for future use, 1019.
Vegetables compos'd by the Hortus Britannicus, ar-
ranged according to the Linnaean system, 588; the
Jussieuan system, 589; to the departments of horticulture, 858.
Vegetables which first attracted man's attention as
food, 96.
Vegetation to accelerate or force, operations for, 376.
Vegetation to retard, operations for, 2177.
Vecelea, pentan. dig. and caryophylleae, a H. an.
Spain, of common culture.
Voltheima, hexan. monog. and hemerocallidea, G.
peren. C. B. S. bulbs, which grow in light soil, and
are readily increased by offsets; or the leaves pulled
close to the bulbs, and planted, will de-
pose themselves as their base, as will many other
scaly and coated bulbs.
Venerie, a royal residence at Turin, 77.
Vent. mal, Jardin de la Malmaison: Par E. P. Ven-
ton.
Venus's comb, scandix pecten.
Venus's flytraps, dionea muscipula.
Veratrum, polygam. monog. and melancholeae, H.
peren. Eur. and N. Amer. which grow best in
rich sandy soil, and are increased by dividing at
the root, or by seeds, which should be sown
as soon as ripe.
Verbascum, mullein, pentan. monog. and solanum,
G. peren. and H. peren. bien. and an.
all of easy culture on light soil.
Verbena, vervain, dydian. angios. and verbenacea,
H. peren. bien. and an. Eur. and N. Amer. which
thrive in light and common soil, and are increased
by dividing at the root.
Verbesina, syngen. polyg. supr. and corymbiferia,
S. and E. Ind. and W. Ind. and G. peren. and
H. peren. Amer. which grow in common soil, and
are readily increased by cuttings, seeds, or
dividing at the root.
Vermin and snakes used for, in gardening, 1433. and
1473.
Vernonia, syngen. polyg. aequal. and corymbiferia,
a S. bien. E. Ind. and H. peren. N. Amer. which
grow well in rich loam, and make a fine show in
autumn.
Veronica, speedwell, dian. monog. and scrophulari-
nea, G. tr. and peren. N. Hol. and H. peren. and
an. E. Ind. of easy culture in light soil: the
species are propagated by cuttings under a hand-
glass, and all the rest by seeds, or dividing the root.
Veronica beccabunga, brookline, 600.
Vervain, see Verbena.
Vesicaria, tetrad. alicate and corymbiferia, H. peren.
and an. E. Ind. of common culture.
Vespa vulgaris, the common wasp, 4837.
Vestia, pentan. monog. and polonionica, a G. tr.
Chili, which thrives in loam and peat, and cuttings
root best in a hand-glass.
Vetch, see Vicia.
Viert, his works on gardening, page 1122.
Vibert, his work on gardening, page 1122.
A.D. 1819.
A.D. 1820.
Viburnum, pentan. trig. and caprifolae, a G. tr.
Canaries, and H. tr. Eur. and N. Amer. which
thrive in common soil, and are increased by
layers or cuttings under a hand-glass in a shady
situation; both the G. and H. kinds are early
flowerers, which render them very desirable.
Vicia, a dian. digladiata, dian. and leguminosea, a S.
of easy culture in light soil.
Vicia faba, the common bean, 3612.
Vigne de la Reine, a seat near Turin, 77.
Vilain, Madame, her villa near Ghent, 125.
Villa-farm, 7279; management of, 7430 and 7433.
Villa-ruralis, management of, 7433.
Villaneuve, a seat near Warsaw, 389.
Villarsia, pentan. monog. and gentianella, a G. peren.
and H. peren. aquatics which flower freely.
Vipinum, peren. trig. and monocotyleon, a deca.
and leguminosea, a G. tr. which grows in sandy
loam and peat, and is readily increased by seeds or
cuttings under a bell-glass in sand.
Vinea, peren. trig. monog. and apocynae, a S.
tr. and an. E. Ind. and H. peren. and an. shrub.
Eur. The species grows in light, rich earth, and
flowers the greater part of the year; the cut-
tings are increased by seeds or cuttings under a
bell-glass. The H. sorts are trailers, and are increased by cuttings,
layers, or dividing at the root.
Vine, see Viola.
Vine, a seat in Hampshire, 7594.
Vinery, its construction, 2666.
Vineyard-nursery, at Hammersmith, 7518.
Viola, peren. trig. monog. and violacea, a G. tr.
and H. peren. and an. N. Amer. and Eur. which
grow in light soil, are well adapted for rockwork
or pots, and are readily increased by seeds or
partly divided plants.
Violet, see Viola.
Viper's bugloss, see Echium.
Viper's grass, see Scorzonera.
Virginia, decin. monog. and leguminosea, G. tr.
Afr. and a H. tr. N. Amer. which thrive in loam
and peat, and young cuttings root in sand under a
bell-glass.
Virginian poke, phytolacca decandra.
Virgin's bow, see Clematis.
Viscum, mistletoe, dioec. tetran. and caprifolae, a H.
tr., Euro, 2889.
Visnaga, toothpick, pentan. dig. and umbelliferae, a H.
an. Eur. of common culture.
Visnea, dodce. trig. and ebeebaeae, a G. tr.
Canaries, which grow in loam and peat, and ripened cut-
tings root in sand under a hand-glass.
Vipse, Francis Xavier, his dissertation on the
growth of wine in England, page 1109. A.D.
1786.

Wallachendorf, trian. monog. and hemodoracce, G. peren. C. B. S. bulbs which grow in sandy loam and peat, with little or no water when not in a growing state, and are increased by offsets.

Walter, Walter, M. D., his tracts on gardening, page 1114. A. D. 1811.

Wakefield Lodge, Northamptonshire, 7580.

Walden, W., his works on gardening, page 1125. A. D. 1712.

Waldsteinia, icis. di-pentag. and rosaceae, H. peren. Hungary; very suitable for rockwork or pots; it grows in sandy loam and peat, and is increased by parting at the roots.

Wales, gardens and residences of, 7602.

Walford House, Devonshire, 7600.

Wales, their formation, 1936; in horticulture, 2400; in floriculture, 6105; in landscape-gardening, 7245.

Wall-flower, — see Chelanthus.

Wall-tree nials and other fastenings, 7514.

Wall-trees, their planting and management, 2499.

Wallerius, J. G., his works on gardening, page 1130. A. D. 1792.

Walls in gardening, structures for defence, enclosure, shelter, and the culture of the more delicate fruit-trees, different kinds of, 1550.

Walthall, — his works on gardening, page 1127.

Walthamstow House, Norfolk, 7554.

Walters, monad. pentan. and tilaccce, S. tr. and a bien, E. Ind. and S. Amer, which grow in light, rich soil, and cuttings root in sand under a handglass.

Waltou, a seat in Radnorshire, 7610.

Wampee-tree, cookea punctata.

Wanstead House, Essex, 7592.

Waratah, camellia, — see Camellia.

Waratah, telepa speciosissima.

Wardour Castle, Wiltshire, 7597.

Warsaw, gardens of, 282.

Wart-crush, Coronopus.

Wart-wort, euphorbia helioscopia.

Warton, a seat in Westmoreland, 7592.

Warwick Castle, Warwickshire, 7592.

Warwickshire, gardens and residences of, 7571.

Water, as its constituent parts, how obtained in hot-houses, 1601 and 1883; different modes of procuring and preserving in the open air, 1713 and 1822; forming excavations for, 1719; operating on in landscape, 7210.

Water-cultroo, — see Trapa.

Water-chickweed, months fontana.

Water-cress, — see Nasturtium.

Water-dropwort, — see Eranthis.

Water-henland, phellandrum aquaticum.

Water-horehound, — see Lycopus.

Water-lily, — see Nymphaea and Nuphar.

Water-milfoil, — see Myriophyllum.

Water-plantain, — see Alliana.

Water-soldier, stratolites aloides.

Water-starwort, calibirta aquatica.

Water-terebinth, behindum paliatrum.

Water-wort, elaine hydropiper.

Waterbourne Harrington, a seat in Dorsetshire, 7598.

Waterfalls, their kinds and construction, 1820, and 7295.

Waterford, county of, as to gardening, 7505.

Water-glasses, different kinds of, 1448.

Watering-pot, different kinds of, 1414.

Wattled hurdle (Sat.); a hurdle spaced or wrought of small poles, used to shade beds or rows of young plants, or new-sown seeds, in gardening.

Watton Woodhall, Hertfordshire, 7544.

Watsonia, trian. monog. and iridece, G. peren. C. B. S. which may be treated as isia in the greenhouse, or like the common ranunculus in the open air.

Wax-tree, ligustrum lucidum.

Wayfarer-tree, viburnum lantana.

Weald Hall, Essex, 7542.

Webera, pentan. monog. and rubaccce, S. tr. E. Ind. which thrive in loam and peat, and cuttings root in sand under a hand-glass.

Wedge, wedge, 1322; weaving pincers, 2071.

Weeks, Edward, his works on gardening, page 1114. A. D. 1785.

Weiss, F. W., his works on gardening, page 1121. A. D. 1755.

Welbeck Abbey, Nottinghamshire, 7576.

Wellfield House, a seat in Radnorshire, 7610.

Wells for water, 1713.

Wembly Manor House, Middlesex, 7520.

Wenray Castle, a seat in Shropshire, 7635.

Wenney House, or Gosford House, a seat in East Lothian, 7619.

Wencker, Jean George, his works on gardening, page 1121. A. D. 1769.

Wenelt, G. T. K., his works on gardening, page 1126. A. D. 1804.

Wendlingia, hexan. polyg. and menisperme, a H. tr. N. Amer. which grows in peat soil, and is increased by layers.

Wentworth Castle, Yorkshire, 7582.

Wentworth House, Yorkshire, 7582.

West Beechworth, Surrey, 7527.

West Grinstead Park, Sussex, 7501.

West India, fruits desirable cultivation, 6012.

Westmoreland, county of, as to gardening, 7602.

Westmoreland, gardens and residences of, 7592.

Weston, Sir Richard, his works on gardening, page 1100. A. D. 1704.

Weston, Richard, Esq., his works on gardening, page 1108. A. D. 1770.

Westringia, idyn. gymnos. and labienae, G. tr. Australian, which thrive in sandy loam and peat, and young cuttings root freely under a bell-glass in sand.
Zadntha, syngen. polyg. aequal. and cichoraceae, a H. an. S. Eur. of common culture.
Zaluzania, syngen. polyg. super. and corymboseee, a F. peren. Mex. which grows in rich, light soil, and cuttings root readily under a hand-glass.
Zamia, dicot. polyan. and cycadee, S. and G. tr. C. B. S. W. Ind. and Austral, which grow in light sandy soil, and some species may be increased by suckers.
Zamoyst, a seat in Poland, 283.
Zannichellia, pond-weed, monoe. monandria and naideae, a H. an. an aquatic.
Zanthorrhiza, yellow root, pentan. polyg. and ranunculaceae, a H. tr. which grows in common soil, and is increased by suckers.
Zanthoxylum, toothach-tree, dioecia pentand. and terebinthaceae, a S. and G. tr. and a H. tr. The tender species grow in sandy loam, and cuttings will root in sand under a hand-glass; the hardy sorts in any soil, and cuttings of the roots will shoot into plants in bottom heat.
Zapana, didyn. anglos. and verbenaceae, a S. and G. peren. W. Ind. and Amer. which grow in light, rich soil, and cuttings root freely under a hand-glass.
Zarriztina, or Tzaritzina, a palace and gardens near Moscow, 292.
Zarskoje-selo, or Tzarskoje-selo, an imperial residence near Petersburg, 157.
Zea, Indian corn, monoe. trian. and graminea, a H. an. Amer. of easy culture, 4335.
Zieria, tetran. monoe. and rutaceae, a G. tr. N.S.W. a pretty plant, which grows in sandy loam and peat, and young cuttings root in sand under a bell-glass.
Zingiber, ginger, monan. monoe. and scitamineae, S. peren. which grow in light, rich soil, and are increased by dividing at the root.
Zimia, syngen. polyg. super. and corymboseee, H. an. S. and N. Amer. of common culture.
Zizania, monoe. hexan. and gramineae, a H. an. N. Amer. an aquatic which only requires to be sown in shallow water or on the margin of a pond.
Ziziphora, dian. monoe. and labiateae, H. tr. peren. and an. Eur. which grow freely in rich, light soil, and are increased by seeds or cuttings.
Zizyphus, pentan. monogynia and rhamnea. S. G. and H. tr. As. Af. and Eur. of which the tender kinds grow well in loam and peat, and cuttings root in sand under a hand-glass; the H. species are increased by seeds or ripened cuttings under a hand-glass.
Zizyphus lotus, the true lotus, and Z. jujuba, the jujube-tree, 6016.
Zoega, syngen. polyg. frut. and cynarocaphelae, a H. an. Levant, of the usual culture.
Zornia, diadel. decan. and leguminoseae, a S. tr. and an. E. Ind. which grow freely in rich, light soil, and cuttings root easily under a hand-glass.
Zopfi, K., his work on gardening, page 1126. A. D. 1798.
Zygophyllum, bean-caper. decan. monoe. and rutaceae, G. tr. and a H. peren. C. B. S. which thrive in loam and peat, and cuttings root readily under a hand-glass.

THE END.
